PAUL I (1901–1964), king of the Hellenes from 1947, was born in Athens on Dec. 14, 1901, the third son of the future King Constantine by his wife Sophia of Prussia. He was educated at the Greek Naval Academy. He left Greece on June 12, 1917, when his father, acceding to the demands of the Allies that he should leave the country, appointed his second son, Alexander, to be king in his place. On the death of King Alexander (Oct. 25, 1920) the throne was offered to Prince Paul, but he declined it. He returned to Greece on Dec. 20, 1920, when his father was recalled. King Constantine abdicated on Sept. 27, 1922, being succeeded by his eldest son George; and Prince Paul then became *diadoch*, or crown prince. As republican feeling grew in the country, Prince Paul in December 1923 left Greece once more with his brother, ex-King George. He spent much of his time during the next ten years in the United Kingdom or in the United States. In October 1935 King George was recalled, and Prince Paul returned to Greece with him, resuming his career as an officer in the Greek Navy. He served on the staff during the Albanian campaign (1940–41), escaped from occupied Greece to Allied territory, and spent some time in South Africa.

Paul ascended the throne on the death of King George on April 1, 1947. His accession coincided with the assumption by the United States of responsibility for assisting his country in its economic recovery from World War II and in the war against the Communist guerrillas, which lasted till 1949. There was political instability until the premierships of Field Marshal Alexandros Papagos (1952–55) and Konstantinos Karamanlis, under whom the dispute with the United Kingdom and Turkey over Cyprus was temporarily settled.

Paul had married Princess Frederika of Brunswick (b. April 18, 1917) on Jan. 9, 1938, and had a son, Constantine (b. June 2, 1940), and two daughters, Sophia (b. 1938) and Irene (b. 1942). He died at Athens on March 6, 1964. (B. S.-E.)

PAUL OF AEGINA (PAULUS AEGINETA) (*c.* 615–690), the last of the great Greek compilers, was born on the island of Aegina. He traveled widely among the Arabians and flourished during the Muslim conquest. He was the last great physician of Byzantine culture to practice and teach in Alexandria just prior to the destruction of the great city in 640 by the forces of the caliph Omar I. Although little is known of his personal life, it is certain that Paul's obstetrical skill placed him in great demand among the Arabians. Much of his material is taken from Galen, Oribasius and Aëtius.

Greek manuscripts of the following works are extant: *Epitomae medicae libri septem*, *De succedaneis ex Galeno*, *De urinis libri VII*, *De mensuris et ponderibus* and *Excerpta varia*. There are Arabic manuscripts in Rome, Munich and Paris. The *Epitome*, Paul's most valuable work, consists of seven books containing practically everything known about the medical arts in his time. Rhazes, in his *Kitabu 'l-Maliki*, copiously employed it, and Al-

bucasis excerpted most of the surgical material in his *Surgical Tracts* from its sixth book. Thus Paul's surgery profoundly affected not only Arabian medicine but also medieval medicine in the west.

See also ABUL KASIM.

See D. Campbell, *Arabian Medicine* (1926); B. Gordon, *Medieval and Renaissance Medicine* (1960). (B. L. G.)

PAUL OF SAMOSATA (3rd century A.D.), heretical bishop of Antioch and proponent of a kind of Adoptionist (*see* ADOPTIONISM) doctrine on the nature of Christ. The only indisputably contemporary document concerning him is a letter written by his ecclesiastical opponents and preserved in Eusebius' *Church History* (bk. vii, ch. 30), according to which he was a worldly cleric of humble origin who became bishop of Antioch in 260.

Paul held that it was a man who was born of Mary, through whom God spoke his Word (*Logos*). Jesus was a man who became divine, rather than God become man. Paul's Christology was therefore a speculative form of the Adoptionism found among the primitive Ebionites of Judaea; in Theodotus and Artemon of Rome; and perhaps in other early Christian writers (and suggested by phrases in the New Testament such as Acts 2:36). Lucian (*q.v.*), the great exegete of Antioch, and his school were influenced by Paul and link him with Arianism. The later Paulicians of Armenia may have claimed to continue his traditions, hence their name.

Between 263 and 268 at least three councils were held at Antioch to debate the bishop's orthodoxy. The third synod condemned his doctrine and deposed him, nominating Domnus as bishop and notifying the bishops of Rome and Alexandria of the decision in the letter referred to above. But Paul enjoyed the patronage of Zenobia, queen of Palmyra, to whom Antioch was then subject, and it was not until late in 272, when the emperor Aurelian defeated Zenobia and brought Antioch under imperial rule again, that the sentence of deposition could be executed.

From the scattered fragments of Paul's writings his historical and philosophical interests can only be surmised. The Council of Nicaea in 325 condemned the Paulianists to be rebaptized (as not believing in the Trinity); but, paradoxically, the term consubstantial (Western counterpart of the Greek *homoousios*), condemned at the synod of Antioch in Paul's sense of the identity of the Father and his Word, became the watchword of orthodoxy and its condemnation a source of embarrassment. *See* also MONARCHIANISM.

Leclercq, *Histoire des conciles*, vol. i (1907); H. de Riedmatten, *Les actes du procès de Paul de Samosate, Étude sur la christologie du IIIe au IVe siècle* (1952). (E. R. Hv.)

PAUL, (CHARLES) KEGAN (1828–1902), English author and publisher, was born on March 8, 1828, at White Lackington, Somerset. Educated at Eton and at Exeter College, Oxford, he was ordained deacon in 1851 and accepted a curacy at Tew in Oxfordshire. Two years later he returned to Eton as a chaplain and later became a master. Through his friendship with Charles Kingsley he became associated with the Christian Socialists F. D. Maurice and Tom Hughes. After Bishop Wilberforce's objection to his almost Unitarian outlook, Paul left Eton in 1862 for Sturminster Marshall, Dorset, and broke with the Church of England in 1874; in 1890 he became a Roman Catholic.

In 1877 he became a partner in the publishing firm of Henry S. King, and, on King's retirement in 1881, Paul took over, inaugurating the house of C. Kegan Paul and Co. In the same year he took in A. C. Trench, who, as proprietor and with Paul as literary adviser in Kegan Paul, Trench and Co., published poems by Tennyson and William Barnes, Meredith's *The Egoist*, R. L. Stevenson's first books, and Gen. Charles George Gordon's *Journals*. In 1889 the firm merged with the late Nicholas Trubner's Oriental publishing business, following a take-over bid by Horatio Bottomley. Later, in 1911, the firm amalgamated with Routledge, but the two remained separate companies until 1947 when they became Routledge and Kegan Paul.

Kegan Paul died on July 19, 1902. His works and writings included *William Godwin, His Friends and Contemporaries* (1876), *Memories* (1899), numerous books and articles on faith and religion, and translations, including Goethe's *Faust* (1873) and Pascal's *Thoughts* (1885). (Co. E. F.)

PAUL-BONCOUR, JOSEPH (1873–), French left-wing politician, and for 16 years France's permanent delegate to the League of Nations. He was born at St. Aignan, Loir-et-Cher, on Aug. 4, 1873. After leaving the university and joining the bar, he apprenticed himself to politics as private secretary of P. M. R. E. Waldeck-Rousseau. His book *Le Fédéralisme économique* (1900) showed his interest in trade unionism. He was elected deputy as Independent Socialist in 1909 for his native *département*, and was minister of labour in 1911. He lost his seat in 1914, returned to parliament as a Socialist after World War I, but resigned from the party in 1931 and thereafter presided over a group of Independent Socialist deputies. Paul-Boncour was minister of war in Édouard Herriot's government of June–December 1932, prime minister December 1932–January 1933, and minister of foreign affairs in his own government, as well as under Édouard Daladier, Albert Sarraut, and Camille Chautemps (December 1932–January 1934). He was again minister of foreign affairs under Sarraut (January–June 1936) and in Léon Blum's second ministry (March 1938). In June 1940 Paul-Boncour advocated the continuation of the war from Algiers and voted against Marshal Philippe Pétain in July. A member of the consultative assembly in 1944, he led the French delegation at San Francisco after Georges Bidault's departure and signed the UN charter on behalf of France. He was a senator during 1946–48. (D. R. GE.)

PAULDING, JAMES KIRKE (1778–1860), U.S. public official and man of letters chiefly remembered for his early advocacy and use of native American material in literature, was born in Dutchess (now Putnam) County, N.Y., on Aug. 22, 1778. Starting his public career in 1815 as secretary of the Board of Navy Commissioners, he became in 1824 a Navy agent in New York City, and from 1838 to 1841 he served as secretary of the Navy under Pres. Martin Van Buren.

His literary work, however, overshadows his routine labours as a government official. As a boy of 18 he went to New York City, where he formed a lasting friendship with the Irvings. This association aroused his enthusiasm for literature, and he and Washington Irving founded the *Salmagundi* (1807–08), a periodical consisting mainly of light satires on local subjects. The outbreak of hostilities between England and America encouraged the assertion of Paulding's nationalism; in *The Diverting History of John Bull and Brother Jonathan* (1812) and *The Lay of the Scottish Fiddle* (1813), he satirized England's conduct toward America during the war. The same spirit of nationalism found expression in two satires on the English traveler entitled *A Sketch of Old England: by a New England Man* (1822) and *John Bull in America* (1825).

The advantages and hardships of western migration are the theme of *The Backwoodsman* (1818), a poem written to call the American author home in his search of literary themes. Novels, such as *Koningsmarke* (1823), *Westward Ho!* (1832), and *The Old Continental* (1846), represent Paulding's attempts to employ the American scene in fiction. His popular play, *The Lion of the West* (1831; ed. by J. N. Tidwell, 1954), introduced frontier humour to the stage by depicting a character based upon Davy Crockett (*q.v.*); the latter, as a consequence, inaugurated the long series of Davy Crockett publications. In his *Life of Washington* (1835), once commended by Edgar Allan Poe, lies further evidence of his staunch Americanism. Plain, even at times vulgar in style, he yet possessed a playful irony which he shared with the New York writers of his day.

BIBLIOGRAPHY.—W. I. Paulding, *Literary Life of James K. Paulding* (1867), which contains selections from his writings; A. L. Herold, *James Kirke Paulding* (1926), has a good bibliography. For backgrounds, *see* K. B. Taft (ed.), *Minor Knickerbockers* (1947). (N. F. A.; X.)

PAULET (PAWLET or POULETT), the name, derived from Pawlett near Bridgwater in Somerset, of a well-known English family, different branches of which have held the baronies of St. John of Basing (from 1539), of Poulett of Hinton St. George (from 1627), and of Pawlet of Basing (1717–54), the earldoms

of Wiltshire (from 1550) and of Poulett (from 1706), the marquessate of Winchester (from 1551), and the dukedom of Bolton (1689–1754).

The first Paulet of whom anything is certainly known was Sir John Paulet (d. 1356). His grandsons Thomas (d. 1407) and William (d. 1436/37) were the ancestors respectively of the Earls Poulett and of the marquesses of Winchester.

Sir William Poulet (d. 1488), son of Thomas, married Elizabeth, daughter and heiress of John Denebaud of Hinton St. George in Somerset. Their great-grandson, Sir Amyas (*c.* 1536–88), had charge of Mary Stuart from 1585 until her execution in February 1587. Sir Amyas's grandson, John (*c.* 1585–1649), created Baron Poulett of Hinton St. George on June 23, 1627, fought for Charles I in the Civil War. His great-grandson, another John (*c.* 1668–1743), was created Viscount Hinton of Hinton St. George and Earl Poulett on Dec. 24, 1706. From him is descended the 8th earl, George Amias Fitzwarrine Poulett (1909–).

Sir John Paulet (d. 1437), son of William (d. 1436/37), married Constance, a co-heir of Sir Hugh de Poynings, 6th Baron St. John of Basing, Hampshire. His grandson, Sir William (*c.* 1483–1571), was created Baron Seynt (St.) John of Basing on March 9, 1539. Lord president of the council (1547–50), he was created earl of Wiltshire on Jan. 12, 1550, and marquess of Winchester on Oct. 11, 1551. He held the post of lord high treasurer from 1550 until his death. His great-grandson William (*c.* 1560–1629), 4th marquess, entertained Queen Elizabeth I at Basing for 13 days in September 1601. His son John (*c.* 1598–1675) held Basing House for Charles I until it was sacked by Oliver Cromwell's troops in October 1645. His son Charles (*c.* 1630–99) was created duke of Bolton on April 9, 1689. For his immediate descendants, *see* Bolton, Dukes of. On the death without male heirs (Dec. 25, 1794), of the 6th duke, Harry, the dukedom became extinct, while the other honours passed to George Paulet (1722–1800), a descendant of the 4th marquess. The 17th marquess of Winchester is Richard Charles Paulet (1905–).

PAULI, WOLFGANG (1900–1958), Austrian physicist, born in Vienna, April 25, 1900, was awarded the 1945 Nobel Prize for physics "for the discovery of the exclusion principle, also called the Pauli principle." He received his early education in Vienna and then studied under Arnold Sommerfeld at the University of Munich, where he took his doctor's degree in 1921. He spent a year as assistant to Max Born at the University of Göttingen and a further year with N. H. D. Bohr at Copenhagen. In 1923 he was appointed lecturer at the University of Hamburg, where he remained until 1928 when he became professor of theoretical physics at the Federal Institute of Technology in Zürich, Switz. Under his direction this institution became a great centre of research in theoretical physics in the years preceding World War II. In 1935–36 he was visiting professor at the Institute for Advanced Study (Princeton University) and he held similar posts at the University of Michigan in 1931 and 1941 and at Purdue University in 1942. In 1940 he was appointed to the chair of theoretical physics at the Institute for Advanced Study; and in 1946 he became a naturalized United States citizen. Following World War II he returned to Zürich. Pauli became one of the most brilliant of the mid-20th-century school of physicists. While still a student he wrote a masterly exposition of the theory of relativity. The work for which he received the Nobel Prize relates to quantum mechanics (*q.v.*) and played an important part in the wave theory of the atom. Pauli was also the first to posit (1931) the existence of the neutrino (*see* Particles, Elementary). He died in Zürich on Dec. 15, 1958.

See S. A. Goudsmit, "Pauli and Nuclear Spin," *Physics Today*, vol. 14 (June 1961). (W. J. Bp.; X.)

PAULICIANS, a dualist Christian sect, influenced most directly by Marcionism and Manichaeism, which originated in Armenia in the 7th century. Most of what is known of them comes from the *Historia Manichaion* by Peter of Sicily, who was sent by the Byzantine emperor Basil I to the Paulician stronghold of Tephrice to make peace (869). The identity of the Paul after whom the Paulicians are called is disputed.

The fundamental doctrine of Paulician dualism is that "there are two principles, an evil God and a good God; the former is the creator and ruler of this world, the latter of the world to come." From this they deduced the docetic doctrine (*see* Docetism) that Jesus was the son of Mary not in truth but only in seeming, because the good God could not have taken flesh and become man. Like other dualist sects the Paulicians, though recognizing the Scripture as uniquely authoritative, rejected the Old Testament and also the Epistles of St. Peter. They especially honoured St. Luke's Gospel and the Epistles of St. Paul. Their belief that all matter was the creation of the evil God led them to reject the sacramental efficacy of water, bread, wine, and oil, and therefore all the seven sacraments, though they later conformed to the practices of the church to escape detection and persecution. They rejected the divine establishment of the church and in their own worship did not use its liturgy and rites. Their rejection of the sacrament of orders made them anticlerical; their early leaders they called merely "companions in travel" (Acts 19:29).

The founder of the Paulicians seems to have been an Armenian, Constantine (fl. between 641 and 648), who took the additional name of Silvanus (one of St. Paul's companions). He gave a more distinctively Christian character to the Manichaeism which at that time was prevalent in the Asiatic provinces of the Byzantine Empire (*see* Manichaeism). The sect seems early to have started a widespread political and military rebellion within the empire. Between 668 and 698 Constantine III and Justinian II sent two expeditions to repress it. Constantine-Silvanus was stoned to death, and his successor, Simeon-Titus, was burned alive. In the early 9th century Paulicianism was revived. It expanded into Cilicia and Asia Minor under Sergius-Tychicus, who made it strong enough to survive the persecution and massacre instigated by the emperor Michael I and the empress Theodora. The number and power of the Paulicians were at their greatest under their leaders Carbeas and Chrysochir in the third quarter of the 9th century. An expedition sent by Basil I in 872 broke their military power, but they survived in Asia at least until the Crusades. Their importance after the 9th century lay chiefly in Thrace, whither many Paulicians were forcibly transported (757, 778, *c.* 970) to serve as a frontier force against the Bulgarians. Paulician doctrines were disseminated among the Macedonians, Bulgarians and Greeks, especially among the peasants, and they contributed much to the development of the doctrines and practices of the Bogomils (*q.v.*), who first appeared in Macedonia in the early 10th century.

See S. Runciman, *The Medieval Manichee* (1947); D. Obolensky, *The Bogomils* (1948). (R. R. Bs.)

PAULING, LINUS CARL (1901–), U.S. chemist, winner of the Nobel Chemistry Prize for 1954 and the Nobel Peace Prize for 1962, who discovered fundamental principles determining the nature of the chemical bond and the structure (shape and size) of molecules, and their application to the explanation of the properties of matter. He was born on Feb. 28, 1901, in Portland, Ore., and educated at Oregon State College (Corvallis) and the California Institute of Technology (Pasadena). He joined the staff of the California Institute of Technology in 1922.

In large measure his work led to the general realization that the nature of the chemical bond and molecular structure is the central and most fruitful theme of modern chemistry. His discoveries about the nature of the chemical bond include directed valence and the hybridization of bond orbitals, electronic structure, and magnetic properties, and the effect of resonance on the shape and stability of molecules (*see* Resonance, Theory of).

From 1936 he and his colleagues applied this knowledge to the study of the properties of living systems. Their work includes the discovery of some of the arrangements of polypeptide chains in proteins, especially a linear helical structure called the α-helix, and the discovery that an abnormality in the molecular structure of hemoglobin is associated with sickle cell anemia, a hereditary disease. (N. Dx.)

PAULINUS, SAINT, of Nola (Meropius Pontius Anicius Paulinus) (353–431), bishop of Nola (in Campania, southern Italy) and one of the most important and attractive Christian Latin poets of his time, was born at Bordeaux, where his family, of Roman patrician origin, was settled. His father was

rich and influential and Paulinus, who was the favourite pupil of Ausonius (*q.v.*), was marked for a public career; he became successively a Roman senator, consul, and governor of Campania. Though not baptized until 389, he was brought up as a Christian and was dedicated to St. Felix, whose tomb at Nola was on one of the family estates. Returning to Aquitaine, he married a Spanish lady, Therasia, with whom in 389 he retired to Spain. The death of their only child in 392 made them decide to forsake the world; they sold their possessions in Gaul and Spain, and in 395, when Paulinus was already in priest's orders, they settled at Nola to live a life of ascetism and boundless charity.

This act of renunciation created a profound impression. Paulinus' old master Ausonius uttered his reproaches in verse to which Paulinus replied in poetical epistles. This exchange belongs to the time when Paulinus was still in Spain. He also corresponded in poetical epistles with Nicetas of Remesiana. His verses, in lyric measures, show how a Christian poet could subdue rhetoric to Christian ends. His poems as a whole abound in reminiscences of classical authors such as Virgil, Horace, Ovid, and Lucan, for he could not forget the methods of the schools. His charm as a poet is best seen in his poems on the feast day of St. Felix.

The collection of his letters is of equal interest, as he corresponded with famous men of his day: Augustine, Jerome, and Sulpicius Severus. His prose style, often rhetorical and exuberant, never descends to puerilities. He could describe in dignified language his cold reception by the pope, or satirize the ignorance of those who could not perceive the beauty of the life of renunciation, but his letters breathe above all the atmosphere of what has been called the cult of Christian friendship. About 409 Paulinus was consecrated bishop of Nola, where he died June 22, 431. His feast is still celebrated on the anniversary of his death.

Bibliography.—Works in J. P. Migne, *Patrologia Latina*, vol. lxi (1847) and W. von Hartel (ed.) in *Corpus Scriptorum ecclesiasticorum Latinorum*, vol. xxix–xxx (1894). *See* also A. Baudrillart, *S. Paulin, évêque de Nole* (1905); P. Labriolle, *La Correspondance d'Ausone et de Paulin de Nole* (1910); P. Fabre, *Essai sur la chronologie de l'oeuvre de S. Paulin de Nole* (1948); P. Fabre, *S. Paulin de Nole et l'amitié chrétienne* (1949); F. J. E. Raby, *History of Christian Latin Poetry*, 2nd ed. (1953); N. K. Chadwick, *Poetry and Letters in Early Christian Gaul* (1955). (F. J. E. R.)

PAULINUS, SAINT (d. 644), first bishop of the Northumbrians and bishop of York, was sent to England by Pope Gregory I in 601 to assist St. Augustine in his mission. He was consecrated in 625 and escorted the daughter of Aethelberht to the Northumbrian king Edwin (*q.v.*). As a result of his preaching, in 627 Edwin was baptized and assigned York to Paulinus as his see. In 632 Edwin was slain at Hatfield Chase and Paulinus retired to Kent, where he became bishop of Rochester. He received the pallium in 634 and died in 644. His feast day is October 10.

See Bede, *Historia ecclesiastica*, ed. by C. Plummer, vol. ii (1896); R. H. Hodgkin, *A History of the Anglo-Saxons*, vol. i, pp. 273–280 (1935).

PAULIST FATHERS (Society of Missionary Priests of St. Paul the Apostle; C.S.P.), founded in 1858 by Isaac Hecker and four other Redemptorist priests, are dedicated to the conversion of non-Roman Catholics. Except for establishments in Toronto, Ont., Johannesburg, S.Af., and Rome, the society exists only in the United States. *See* Hecker, Isaac Thomas; Orders and Congregations, Religious.

PAULO AFONSO FALLS are formed by the confluence of several branch streams about 190 mi. from the mouth of the São Francisco River on the Alagôas-Bahía border in Brazil. Set amid splendid scenery in the centre of a national park, the rapids reach a height of 279 ft. The falls are the site of a great hydroelectric project, begun in the late 1940s, to supply power to northeast Brazil. *See* São Francisco.

PAULSEN, FRIEDRICH (1846–1908), German philosopher and advocate of educational reform, was born at Langenhorn in Schleswig on July 16, 1846. He was educated at Erlangen, Berlin, and Bonn. He was professor of philosophy and pedagogy at Berlin from 1878 until his death there on Aug. 14, 1908. Paulsen was the greatest of the pupils of G. T. Fechner and his major philosophical work, *Einleitung in die Philosophie* (1892; Eng. trans. 1895), which attempted an epistemological account of our knowledge of the psychophysical, gave great prominence to Fechner's doctrine of panpsychism. He also paid considerable attention to Kantian philosophy, on which he wrote several studies, including *Immanuel Kant, sein Leben und seine Lehre* (1898; Eng. trans. 1902). In general, however, Paulsen's best-known philosophical works are somewhat oversimplified and his ideas unoriginal (partly because he deliberately wrote for a wide audience); he is best remembered for the part he played in the reorganization of higher education in Germany by leading the attack on the monopoly of the *Gymnasien* in the preparation of students for the university. His educational writings include *Geschichte des gelehrten Unterrichts auf den deutschen Schulen und Universitäten vom Ausgang des Mittelalters bis zur Gegenwart* (1885; Eng. trans. 1895), and *Das deutsche Bildungswesen und seine geschichtlichen Entwicklung* (1906; Eng. trans. 1908). He also wrote a *System der Ethik, mit einem Umriss der Staats- und Gesellschaftslehre* (1889; Eng. trans. 1899).

See T. Lorenz (trans. and ed.), *Friedrich Paulsen, an Autobiography* (1938).

PAULUS (Silentiarius) (d. A.D. 575), Greek poet, surnamed from his office of "silentiary" or usher at the court of Justinian I, was a member of the circle of classicizing writers at the imperial court in Constantinople. He was a contemporary and friend of Agathias. He wrote two elaborate poems describing Justinian's new church of Hagia Sophia, read at the dedication of the church in 537, which are important sources for the history of Byzantine art and architecture. About 80 of his epigrams on various subjects are preserved in the Greek Anthology.

Bibliography.—Poems on Hagia Sophia ed. by P. Friedländer with introduction and commentary (1912), Italian verse trans. with commentary by A. Veniero (1916). *See* also S. G. Xydis in *Art Bulletin* 29:1–24 (1947), and on the epigrams *see* B. L. Gildersleeve in *American Journal of Philology* 17:42–72 (1917). (G. Do.)

PAULUS, FRIEDRICH (1890–1957), German army officer, field marshal in World War II, was born at Breitenau, Hesse, Sept. 23, 1890. He served in World War I and helped plan World War II. He was chief of operations from Sept. 1940 to Jan. 1942, when Hitler entrusted him with the command of the 6th army in southern Russia. By late summer he reached Stalingrad (now Volgograd), high-water mark of Nazi conquest. Then, cut off by the Soviet counter-offensive that started in November, Paulus and his 300,000 men were abandoned by Hitler. He surrendered remnants of his army, after a bitter defense, on Jan. 31, 1943. On the same day, Berlin announced his promotion to the rank of field marshal.

In Soviet custody, Paulus joined the National Free Germany committee to agitate against the Nazis and he later testified at the Nürnberg trials. After his release in 1953, he settled in East Germany and publicly attacked the West German government for its rearmament and pro-United States policies. Paulus died in Dresden on Feb. 1, 1957. (P. N. T.)

PAULUS (older form Paullus), **LUCIUS AEMILIUS,** surnamed Macedonicus (*c.* 229–160 B.C.), Roman general and patrician, son of the consul of the same name who fell at Cannae. Praetor in 191 and consul in 182, he campaigned against the Lusitanians (191–189) and the Ligurian Ingauni (181). Consul again in 168, he ended the Third Macedonian War at Pydna (*q.v.*). A commemorative monument was erected at Delphi, and the captive king Perseus was shown at Paulus' triumph. He settled Greece and on senatorial orders he sacked the cities of Epirus. He was censor in 164 and died in 160. At his funeral games the *Hecyra* of Terence was acted for the second and the *Adelphi* for the first time. Of the vast sums brought by him into the Roman treasury from Spain and Macedonia he kept nothing for himself. A fine general and a strict disciplinarian, an aristocrat, yet popular, he united Roman tradition with Hellenism. His most famous son was Scipio Aemilianus.

Bibliography.—Plutarch, *Aemilius Paulus;* Polybius, xxix–xxxi; Livy, xliv, 17 ff.; xlv–xlvi; H. H. Scullard, *Roman Politics, 220–150 B.C.* (1951). (H. H. Sc.)

PAULUS DIACONUS (Paul the Deacon) (*c.* 720–?799), the historian of the Lombards, came of a noble Lombard family in

Friuli, and was educated at the royal court at Pavia. During the reigns of Ratchis and Desiderius he remained in close contact with the royal family. He taught Desiderius' daughter Adelperga and probably followed her to Benevento after her marriage with its duke. he composed for her his first historical work, the *Historia Romana* (ed. by A. Crivelluci, 1914), an expansion and continuation of Eutropius's *Breviarium*. Probably after the collapse of the Lombard state in 774, he entered the monastery of Monte Cassino. In 782 he went to Charlemagne to plead for his brother Arichis who had taken part in an anti-Frankish rising; he thus joined the group of scholars whom Charlemagne had gathered at his court, and became a prominent figure in the Carolingian Renaissance. His interest in classical Latin grammar is reflected in his *Epitome* of Festus' *De verborum significatu*, while his poems (ed. by K. Neff, *Die Gedichte des Paulus Diaconus*, 1908) are outstanding examples of the classical revival. He continued his historical writing with a history of the bishops of Metz, which became a model for later similar histories, and with a life of Gregory the Great. But his greatest achievement was his *Historia Langobardorum* (ed. by L. Bethmann and G. Waitz, in *Monumenta Germaniae Historica, Script. rer. Langob.*, II, 1878; also ed. *in usum scholarum*; Eng. trans. by W. D. Foulke, 1907) to the death of Liudprand (744). Based on written sources such as the *Origo gentis Langobardorum*, and on oral tradition, which would otherwise have been lost, it is the work of a scholar and a patriot, and remains the most important source of Lombard history. The *Historia* was written in Monte Cassino where Paul had returned by 787, and where he died on April 13, perhaps in 799. His other works include a collection of homilies for the ecclesiastical year, and a commentary on the Rule of St. Benedict.

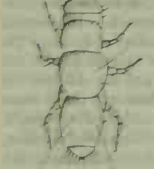
PAUROPODA, a class of many-legged, air-breathing arthropods that superficially resemble tiny centipedes or millipedes. In fact, when Sir John Lubbock announced the discovery of pauropods in 1866, he regarded them through a representative genus *Polyxenus*, as linking forms between centipedes and millipedes. The largest pauropods are only about 1 mm. in length, the smallest about 0.5 mm. Their soft, pale or whitish bodies may be found in decaying vegetation upon moist soil; they are quite inconspicuous in this habitat where they feed and lay their eggs.

FROM J. LUBBOCK IN "TRANSACTIONS"

FIG. 1.—PAUROPUS HUXLEYI ADULT SEEN FROM ABOVE (greatly magnified)

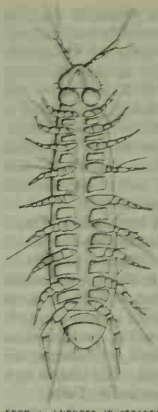
The body is composed of 12 segments, but because of the coupling of dorsal plates (tergites) of the first 10 segments, the number appears to be less than 12 when the animal is viewed from above. The adult has nine evident pairs of legs. Pauropods resemble centipedes in body form and in number of legs per segment: one pair of legs is found on each true segment except the last two, which are legless; the legs of segment one are so degenerate that they are hardly noticeable. Fusion of tergites indicates a beginning of the process, carried to completion in millipedes, of the doubling of segments.



FROM J. LUBBOCK IN "TRANSACTIONS"

FIG. 2.—YOUNG PAUROPUS WITH ONLY THREE PAIRS OF LEGS (greatly magnified)

The most distinctive characteristic of pauropods is the possession of branched antennae, a characteristic separating them from other arthropods. Each antenna consists of four segments, of which the end one bears two branches; the upper branch is a simple filament of many segments; the lower branch bears two filaments, between the bases of which is a characteristic rounded knob (globulus) thought to be a special sense organ. Eyes are absent, but behind the base of each antenna is an eyelike spot (pseudoculus) possibly homologous with the organ of Tömösvary of centipedes. The mouthparts resemble those of millipedes.



FROM J. LUBBOCK IN "TRANSACTIONS"

FIG. 3.—PAUROPUS HUXLEYI SEEN FROM BELOW (greatly magnified)

The internal structure is relatively unspecialized; pauropods lack both special respiratory and circulatory systems. The simple alimentary canal, though it bears a pair of degenerate excretory tubules (Malpighian tubules), appears to effect excretion chiefly through its own epithelium. As in millipedes the reproductive organs open at the bases of the second legs, males having a pair of penes. From the egg arises a pupoid larva, which in turn gives rise to a free larva having three pairs of legs. Later larval phases have been observed with five, six and eight pairs of legs.

Pauropods are classified under three families: Pauropododae, Eurypauropodidae and Brachypauropodidae.

BIBLIOGRAPHY.—A good summary is given by K. W. Verhoeff in Bronn's *Klassen und Ordnungen des Tier-reichs* (1933–34); and C. Graf Attems in Kukenthal and Krumbach's *Handbuch der Zoologie* (1926). (R. V. C.)

PAUSANIAS, of the Agiad royal family of Sparta, succeeded his father Cleombrotus in 480 B.C. as regent for Leonidas' young son Pleistarchus. As commander of the Greek army he defeated the Persians under Mardonius at Plataea in 479 (*see* GRECO-PERSIAN WARS). Next year he led an allied fleet to Cyprus, then captured Byzantium, to command the crossing between Asia and Europe. Here his arrogance and his adoption of Persian clothes and manners offended the allies and raised suspicion of treachery. Recalled to Sparta, he was acquitted on the major charge but was not restored to his command: the allies now separated from Sparta and formed the Delian League (*q.v.*) with Athens. Pausanias returned privately and held Byzantium until dislodged by the Athenians, probably in 477, when he retired to Colonae near Troy. Eventually the Spartan ephors again recalled him, and he obeyed the summons and successfully defied his enemies to bring him to trial. In the end one of his messengers opened and gave to the ephors a letter from Pausanias to the Persian king, and this letter and an overheard conversation between Pausanias and the messenger encouraged the ephors to arrest him. He took refuge in the Temple of Athena of the Brazen House but was walled in and starved to death, probably between 470 and 465.

Pausanias' real plans and the degree of his guilt are hard to estimate. Herodotus had some doubt about the story, whereas Thucydides, writing later and in different circumstances, had none: the Spartans had perhaps made Pausanias a scapegoat for their failure to retain the leadership of Greece. The ephors' long delay in acting against him suggests that he had supporters who believed him innocent, and it is likely enough that he headed a party wishing to dispute the leadership with Athens. But some of his actions do not look innocent, and his agent Gongylus, who held Byzantium for him during his first recall, certainly received large rewards from Xerxes afterward. (A. As.)

PAUSANIAS, Greek traveler and geographer of the 2nd century A.D., was probably a native of Lydia. It has been stated with perfect justice by J. G. Frazer that "without him the ruins of Greece would for the most part be a labyrinth without a clue, a riddle without an answer."

Before visiting Greece he had traveled widely in Asia Minor, Syria, Palestine, Egypt, Macedonia, Epirus, and parts of Italy. His *Description of Greece* takes the form of a tour starting from Attica. It is divided into ten books: (i) Attica and Megara; (ii) Corinth and Argolis; (iii) Laconia; (iv) Messenia; (v) and (vi)

Elis, including Olympia; (vii) Achaea; (viii) Arcadia; (ix) Boeotia; and (x) Phocis, including Delphi. He probably planned to write on the remaining regions as well. The books seem to have been written in the order in which they stand, over a period of about 15 years. No event after about A.D. 176 is mentioned.

The work has no formal preface or conclusion. The author's aim may be inferred from his statement at the close of his account of Attica: "Such (in my opinion) are the *most famous* of the Athenian *traditions* and *sights;* from the mass of materials I have aimed from the outset at selecting the really *notable*." In the hope of giving variety to the topographical details the author intersperses them with lengthy historical disquisitions. In the subsequent books his account of each important city begins with a sketch of its history; in his descriptions he adopts a topographical order. He gives a few glimpses into the daily life of the inhabitants, ceremonial rites and superstitious customs. He frequently introduces history, legend, and folklore; but it is only rarely that he allows something of the scenery to be seen.

He was inspired by interest in the ancient glories of Greece and seems to have had little love for Roman rule. He is most at home in describing the religious art and architecture of Olympia and Delphi and was interested in visiting the battlefields of Marathon and Plataea, in viewing the Athenian trophy on the island of Salamis, the tombs of famous men, and the colossal lion guarding the tomb of the Thebans on the Boeotian plain.

At Olympia he takes note of the ancient quoit of Iphitus inscribed with the terms of the Olympia truce, the tablets recording treaties, and the memorials of victories. At Delphi he marks the trophies of the Athenians, the united Greeks, the Spartans, the Thebans, and the shields dedicated in memory of the repulse and defeat of the Gauls at Delphi. At Athens he sees pictures, portraits, and inscriptions recording the laws of Solon, on the Acropolis the great bronze statue of Athena, and outside the city the monuments of famous men and of all the Athenians who fell in battle, except the heroes of Marathon, "for these, as a meed of valour, were buried on the field."

In the topographical part of his work, he is fond of digressions on the wonders of nature, the signs that herald the approach of an earthquake, the tides, the icebound seas of the north, and the noonday sun which at the summer solstice casts no shadow at Syene (Aswan). His main interest is in works of art: he prefers the works of the 5th and 4th centuries B.C. to those of later times.

In all parts of Greece the accuracy of his descriptions has been proved by the remains of the buildings; but he made appalling mistakes especially when he followed other authors. His style, despite rhetorical artifice, is undistinguished. Pausanias' work was little known in antiquity, but now it is an invaluable guide to the ruins of ancient Greece.

See Teubner Series text by F. Spiro (1903); "Loeb Series" ed. by W. H. S. Jones, H. A. Ormerod and R. E. Wycherley (1918–35). Commentary with trans. by J. G. Frazer (1898). (E. BA.)

PAVANE (Italian PADOVANA, from Padua), a slow 16th-century dance in duple or quadruple rhythm. It became important as the first of the 15th century *basses danses* (popular dances) to enter aristocratic court circles. It traveled to France by way of Spain where its vogue undoubtedly added Spanish characteristics as a result of performances on solemn occasions in the churches of southern Spain. Thus arose the possibly disputable claims of its Spanish origin, and the still widely believed derivation of its name from *pavo* ("peacock"). A stately processional, its basic movements consisted of step close, step close, and step, step, step, close, alternately forward and backward. Customarily followed by the lively Galliard, it retained its popularity as a dance until about 1650. (L. Ilt.)

PAVELIC, ANTE (1889–1959), Croatian nationalist leader, dictator of the independent Croatian state sponsored by the Germans and Italians during World War II, was born at Bradina, in the Bosnia Region, on July 17, 1889. He studied at Zagreb University and later practised law at Zagreb. He joined the nationalist Croatian Party of Rights and became its secretary. In 1920 he was elected city and county alderman at Zagreb. A deputy to the Yugoslav *skupstina* from 1927, he opposed the amalgamating policy of the government. In January 1929, when King Alexander established his dictatorship, Pavelic escaped to Italy where he organized a revolutionary Croatian nationalist movement, the *Ustasa* (insurgent). It was this movement that organized the assassination of King Alexander in Marseilles on Oct. 9, 1934. Aiming to destroy Yugoslavia and to establish an independent Croatian state, Pavelic joined forces with Hungarian, German, and Italian adversaries of the existing territorial settlement in Europe and ultimately became an instrument of Fascist imperialism in the Balkans. In April 1941, when Germany and Italy conquered and dismembered Yugoslavia, an independent Croatian state was established, and Pavelic became the head (*poglavnik*) of the new state. He ruled as a dictator and, because of wide popular opposition to his regime and policy, with ruthlessness and brutality. In May 1945 when the Croatian state ceased to exist, Pavelic left Zagreb to escape capture by Yugoslav Communists. After hiding under false names in Austria and Italy he arrived in Argentina in 1948. In 1957 the Yugoslav government demanded his extradition as a war criminal, but this was refused by the Argentine government. Wounded during an attempt on his life in Buenos Aires (April 10, 1957), Pavelic fled from Argentina and settled secretly in Spain where he died in Madrid on Dec. 28, 1959. (A. S. PA)

PAVIA (ancient TICINUM), a city of Lombardy in northern Italy, capital of the province of Pavia, is situated on the left bank of the Ticino River, 4 km. (3 mi.) above its junction with the Po and 36 km. (22 mi.) S of Milan by road and rail. Pop. (1961) 78,069 (commune). On the other side of the river is the suburb of Borgo Ticino, connected with the city by a covered bridge, the Ponte Coperto, dating from the Middle Ages (rebuilt 1951). Pavia still retains the ancient plan of a Roman *castrum*, with *cardo* (main street running north-south; now called Strada Nuova), *decumanus* (running east-west; Corso Cavour and Corso Mazzini), *quadrivium* or main crossroads (Demetrio), and network of streets for *centuriae* (companies). In the centre of the city stands the cathedral with its vast cupola. Begun in 1488 by Cristoforo Rocchi, and completed in 1898 according to Rocchi's still extant model, the cathedral has the form of a Latin cross. Close by is the Piazza Grande with the ancient Broletto or town hall (12th and 16th centuries) in the background; in the square stands the Palazetto Dei Diversi (14th century). Particularly important are the Romanesque churches, including: S. Michele Maggiore (11th century), the ancient Lombard cathedral where for more than 200 years the medieval "kings of Italy" were crowned; S. Pietro in Ciel d'Oro (12th century), mentioned by Dante, Petrarch, and Boccaccio, with a marble tomb (1362) containing the bones of St. Augustine of Hippo; and S. Teodoro (12th century), decorated with 13th-century Byzantine frescoes and 16th-century stories of saints and virgins. Other churches are the beautiful Gothic Sta. Maria del Carmine (14th century) and S. Francesco (13th century). Other buildings of note are the 16th-century palace of Del Maino and the 18th-century palaces of Botta-Adorno, Brambilla, Olevano, Mezzabarba, Arnaboldi, and Vistarino (all ancient patrician families). In the rooms of the 14th-century castle of the Visconti valuable artistic collections are kept, and the magnificent Romanesque department is devoted to sculptures and mosaics.

The University of Pavia was founded in 1361 by Gian Galeazzo Visconti: it is linked with the ancient law school which was in existence in 825 in the time of Lothair I. The oldest part of the building dates from the 14th century and Maria Theresa of Austria had extensions built in the 18th century. Christopher Columbus once studied there. The colleges of Ghislieri and Borromeo were founded in the 16th century by Pope Pius V and St. Charles Borromeo. The University of Pavia is particularly noted for the study of law, science, medicine, and surgery; and has a central library of more than 400,000 volumes and 1,500 manuscripts. The civic library has 60,000 volumes, principally concerned with local history. The Pinacoteca (Palazzo Malaspina) boasts works by many famous artists and its collection of more than 30,000 prints is one of the most important among such collections in Europe.

Pavia is on the railway from Milan to Genoa. The Naviglio, a

navigable canal along which sand and gravel from the Ticino are transported, runs to Milan; Leonardo da Vinci devised the 12 locks which raise the canal 148 ft. between the two cities. The chief industry is the manufacture of sewing machines. There are also mechanical engineering, ferrous metal working, and the manufacture of thermionic valves and chemicals. The city is an important agricultural centre.

Pavia was originally a Roman municipality, Ticinum, of the Papiria tribe and it increased in importance, owing to its geographical position, in the time of the empire. It was pillaged by Attila in A.D. 452 and by Odoacer in 476 but later became an important centre of Gothic resistance against the Byzantine Empire. From the 6th century, under the Lombards, it was one of the leading cities of Italy, remaining so even when it fell under Frankish dominion in 774. After a series of wars with Milan from the 11th to the 13th century, it was subdued by the Visconti in 1361 and under Gian Galeazzo became the political centre of Italy. In 1525 a notable battle took place between the Spanish emperor and the French king (*see* below). During the 18th century Pavia was occupied variously by the Austrians, French, and Spaniards. It was one of the leading cities of Venetian Lombardy in the campaigns of the Risorgimento.

Battle of Pavia (1525).—The battle took place in the huge park of the Visconti Castle, to the north of Pavia, between Francis I of France and Charles V of Spain. In 1524 the French king occupied Milan and brought against Pavia an army of more than 30,000 men, attacking it from every quarter. But the defense, conducted by the troops of Antonio de Leyva and the Pavians, aided by Swiss militia, forced the French to concentrate their forces in the park of the Visconti. At dawn on Feb. 24, 1525, the imperial troops attacked the French and threw the German infantry, mercenaries of Francis I, into confusion. De Leyva then made a sortie from Pavia and, having destroyed the ranks of Giovanni de Medici, attacked from behind the Swiss reinforcements, annihilating the French army, whose king fell prisoner. The Battle of Pavia showed the superiority of firearms over cold steel and revolutionized military tactics.

Certosa di Pavia.—A Carthusian monastery, the most magnificent religious monument in Lombardy and one of the most beautiful in the world, is situated 8 km. (5 mi.) N of Pavia, on the extreme boundary of the park of the Visconti. Begun in 1396 by Bernardo da Venezia, it was continued by Andrea and Cristoforo Solari and others in a transitional style between Gothic and Renaissance. The facade is a marvelous piece of architecture of Renaissance Lombardy, with a splendid array of sculptures and marbles. In the north transept of the church is the tomb of Lodovico Sforza (il Moro) and his wife by Cristoforo Solari, and in the south transept that of Gian Galeazzo. The terra-cotta ornaments surrounding the slender marble pillars of the small cloister are the work of Rinaldo de Stauris, who executed similar decorations in the great cloister, which is 412 ft. long and 334 ft. wide and contains 24 monks' cells, each in the form of a small house with three rooms and a garden.

G. CHIOLINI

THE CERTOSA DI PAVIA, A CARTHUSIAN MONASTERY COMPLETED IN THE 17TH CENTURY

Pavia Province lies to the south of the province of Milan. It comprises three distinct regions: Pavese, Oltrepò, and Lomellina. Area 1,145 sq.mi. (2,966 sq.km.). Pop. (1961) 514,994. Pavese produces grain, Lomellina rice, and Oltrepò wine. The industrial centres of Lomellina include Vigevano (footwear) and Mortara (carpets, biscuits, and rice processing). Among places of historic interest are Lomello's 8th-century baptistery and Vigevano's Piazza Ducale, to which Leonardo da Vinci contributed. Varzi, Pietra Gavina, and the 4,000-ft. Passo del Brallo and Passo del Giovà in Oltrepò are holiday centres.

Bibliography.—G. Chierici, *Guida alla Certosa di Pavia* (1950); P. Vaccari, *Profili storico di Pavia* (1950), *Pavia nell'alto Medioevo e nell'età comunale* (1956); A. Annovazzi and F. Biancoli, *Pavia e la sua Provincia* (1952). (De. M.)

PAVÍA Y LACY, MANUEL, Marqués de Novaliches (1814–1896), Spanish general who remained loyal to Isabella II in the revolution of 1868, was born in Granada on July 6, 1814. He fought for Isabella in the First Carlist War (1833–39), being appointed colonel for his success at the fall of the castle of Onís and brigadier at the capture of Solsona. In 1840 he was created marqués de Novaliches. He emigrated to France in 1841, and on his return in 1843 took part in the overthrow of Gen. Baldomero Espartero. Pavía became minister of war in 1847. Afterward he was captain general of Catalonia and in 1853, as captain general of the Philippines, he went to Manila and crushed the revolt of the mestizo José Cuesta in 1854. At the revolution which deposed Isabella in September 1868 he was defeated at Alcolea by Gen. Francisco Serrano, and was badly wounded. He emigrated at the accession of Amadeo (December 1870) but returned at the restoration of Alfonso XII (December 1874), when he was restored in his honours and received the Order of the Golden Fleece. He died in Madrid on Oct. 22, 1896. (R. S. Ll.)

PAVÍA Y RODRÍGUEZ DE ALBURQUERQUE, MANUEL (1827–1895), Spanish general who carried out the *coup d'état* of January 1874, was born at Cádiz on Aug. 2, 1827. Appointed captain in 1848 and major in 1854, he joined in 1865 the staff of Gen. Juan Prim whom he supported in the unsuccessful uprisings in 1866 and, after two years in exile, in the successful revolution of September 1868 which deposed Isabella II. After the abdication of King Amadeo (February 1873) and the proclamation of the republic by the *Cortes*, Pavía suppressed (1873) the chief cantonal insurrections in the south of Spain. He was appointed captain general of New Castile in the same year. Pavía hoped to establish a dictatorial, military republic with Pres. Emilio Castelar (*q.v.*), but when, on Jan. 3, 1874, Castelar was defeated by, and refused to dissolve, the *Cortes*, Pavía carried out a *coup d'état* and expelled the *Cortes*. Free from personal ambition he summoned Gen. Francisco Serrano to take over the government. After the restoration of Alfonso XII (December 1874) Pavía was elected to the *Cortes* in 1876. He was captain general of Catalonia (1880–81) and of New Castile (1885–86). He died in Madrid on Jan. 4, 1895.

PAVLODAR, an *oblast* and town in the Kazakh Soviet Socialist Republic, U.S.S.R. Formed in 1938, the *oblast* has an area of 49,344 sq.mi. (127,801 sq.km.). It is divided into 11 *raions* and has two towns and four settlements of town type. Since Dec. 1960 it has formed part of the newly created region of Tselinny Krai (the New Lands Region). The *oblast* lies across the Irtysh River and forms part of the West Siberian Depression. The climate is continental and dry. There are important deposits of coal, copper, gold, and sodium chloride. Main industries are coal mining (Ekibastuz), salt production from the salt lakes, and gold mining (Maikain). More than 3,500,000 ha. are under cultivation (mainly wheat and millet) and dairy cattle are also raised.

The population was 455,013 in 1959, of which 73% was rural. Russians probably predominate over Kazakhs. The towns are

Pavlodar, the administrative centre, and Ekibastuz. In addition to about 580 schools there are several special middle-school training establishments. The main railway is the Tselinograd (Akmolinsk)-Pavlodar-Kulunda line. The Irtysh is navigable and there are many metaled roads.

Pavlodar town has a population (1959) of 90,096. Situated on the Irtysh, it was founded as Koryakovski outpost in 1720 and became the town of Pavlodar in 1861. It has a number of light industries (mostly connected with food), teacher-training and medical institutes, a theatre, and a museum. (G. E. WR.)

PAVLOV, IVAN PETROVICH (1849–1936), Russian physiologist, achieved world renown for his researches on blood circulation, the action of the digestive glands, and the formation of conditioned reflexes. He was awarded the Nobel Prize in 1904 for his work on the physiology of digestion, but his name is known far beyond scientific circles for his systematic experimental studies of conditioning of dogs and other animals. These studies, begun in 1902, profoundly influenced the experimental psychology of learning, while his discovery of techniques for creating "experimental neuroses" in dogs did much to pioneer the scientific approach to the study of human mental disorders. Although Pavlov was unrivaled in the surgical skills and objective methods of animal experimentation, his theory of the cerebral processes in conditioning was much criticized, and his later extension of conditioning principles to account for complex human mental processes, such as language, lacks validity.

THE BETTMANN ARCHIVE, INC.

IVAN PETROVICH PAVLOV

He was born in Ryazan on Sept. 14, 1849, the son of a priest. After four years spent at the Ryazan Seminary, he studied science, then medicine, at the University of St. Petersburg (Leningrad). Having graduated as doctor of medicine (1883), he worked in Germany (1884–86) under two great physiologists, Karl F. W. Ludwig and Rudolf Heidenhain. On returning to St. Petersburg, his first major appointment was to the chair of pharmacology at the Military Medical Academy in 1890. In 1891 he directed the construction of the first surgical department in the world to be set up in a physiological laboratory, at the new Institute of Experimental Medicine.

In 1895 he became professor of physiology at the Military Medical Academy. His honours included election as member of the Russian Academy of Sciences (1906), foreign member of the Royal Society (London, 1907), and honorary fellow of the Royal College of Physicians (London, 1928). His first publications, on blood circulation, date from 1878, and his major work on the physiology of digestion appeared in Russian in 1897 and subsequently in German, French, and English. The account of his 25 years of experimental work on conditioning became available in English first through G. V. Anrep's translation (1927) and W. H. Gantt's (1928).

From 1928 until his death Pavlov concentrated upon applying his conditioning principles to the problems of the psychiatric clinic, as is described in a second book translated by Gantt (1941).

Pavlov died in Leningrad on Feb. 27, 1936. After his death, his conditioning theory and account of cerebral activity retained considerable influence over research in the U.S.S.R. on the higher nervous activity of man. The essence of the Pavlovian approach to the study of complex mental processes is its emphasis on objective experiment, its rejection of the subjectivity of older traditional psychology and of the mind-body dualism supposedly inherent in it.

Pavlov's works available in English include *The Work of the Digestive Glands*, translated by W. H. Thompson (1902); *Conditioned Reflexes*, translated and edited by G. V. Anrep (1927); *Lectures on Conditioned Reflexes*, translated by W. H. Gantt (1928); and *Conditioned Reflexes and Psychiatry*, translated and edited by W. H. Gantt (1941). Gantt's two translations are introduced by useful biographical sketches.

See CONDITIONING; LEARNING; NEUROSES, EXPERIMENTAL; etc. *See* also references under "Pavlov, Ivan Petrovich" in the Index.

PAVLOVA, ANNA (1881–1931), Russian ballerina, the most celebrated dancer of her time, was born Jan. 31, 1881, in St. Petersburg. She studied at the Russian Imperial Ballet School under Ekaterina Vazem and Paul Gerdt, graduating as soloist in 1899. Seven years later, after triumphs in *Swan Lake* and *Giselle*, she was named prima ballerina. She participated in Diaghilev's first Paris season, 1909, but, dissatisfied with her position in the company, she soon withdrew.

In 1910, with Mikhail Mordkin as her partner, she appeared with sensational success at the Palace Theatre, London, and Metropolitan Opera, New York City.

Forming her own company, Pavlova began the series of world tours which continued until her death. Before World War I, she returned regularly to the Mariinsky Theatre, St. Petersburg. She appeared in all the principal countries of North and South America, Europe, Africa, and the Orient, bringing the art of ballet to numerous communities where it was unknown, and inspiring many young dancers. She made her home in London with her husband and manager, Victor Dandré. She died Jan. 23, 1931, at The Hague.

Pavlova's repertoire consisted chiefly of classic ballets, including *Chopiniana, Don Quixote*, and *Coppélia*. Her favourite was *Giselle*. Her superb performance of the famous solo, *The Dying Swan*, created for her in 1905 by Michel Fokine, was legendary.

See Victor Dandré, *Anna Pavlova* (1932); Arthur H. Franks, *Pavlova, a Biography* (1956). (LN. ME.)

PAWNBROKING is the business of advancing loans on the security of goods or chattels. The precise definition of the trade depends on the legislation by which it is regulated. In Great Britain, for example, pawnbroking used to relate to loans not exceeding £10 in a single transaction; this figure was increased to £50 by the Pawnbrokers Act of 1960. There are precise conditions as to the right of the borrower to redeem articles pledged, and of the pawnbroker to dispose of forfeited goods.

From the middle ages to the 20th century pawnshops have attracted the custom of a declining aristocracy. Jewelry and plate form the typical collateral for such loans. In the 19th century the small middle class joined the aristocracy in these transactions as principal borrowers. At the same time, a far poorer class of customers fell into the habit of pledging clothing, bedding and cheap personal effects. In Great Britain the latter is termed by pawnbrokers the "industrial," the former the "city," trade.

The trade of the pawnbroker is one of the oldest known to mankind. It existed in China 2,000 to 3,000 years ago. Greece and Rome were familiar with its operation; they laid the legal foundations on which modern statutory regulation is built. The forces which nurtured pawning, particularly among the poor, were need, habit and convenience. The industrial trade in the 19th and 20th centuries was fed neither by extreme poverty nor by severe unemployment, but by the continuing pressure of family incomes low enough to stimulate borrowing, while regular enough to enable borrowers to redeem pledges. Moreover, occasional interruptions of earning by unemployment and sickness contributed substantially to the growth of pawning. The convenience of having a pawnshop nearby and the habit which grows from the first failure to live within current income strengthened the bond between pawnshop and borrower. It is said that the first half of the 20th century witnessed an important growth of borrowing in Great Britain by the middle class.

In the 20th century, after a long period of income redistribu-

tion and growing social service benefits, it became difficult to assess the relative importance of the various motives which led people to the pawnshop. The meaning of the word "necessity" is very elastic; its boundaries can be made to extend to any reduction in the real income of the indigent. But as long as low incomes, temporary difficulties and shiftlessness among poor and rich alike continue to stimulate demand for borrowing, there will doubtless be willing lenders. The disappearance of the pawnbroker would in many instances enforce readjustment and a new discipline among the poor; in other cases it might promote the growth of different forms of small-scale lending beyond the reach of present legislation. The same thing applies to those who have insufficient or inadequate articles to pledge; this situation might breed an equivalent to the "dolly shop." Such shops specialized in the very small loan, too small to be profitable under the usual conditions.

It would be impossible to estimate to what extent illegal forms of lending still exist, but they can hardly be of anything like the same magnitude, at least in Great Britain, as they were in the past. In the first half of the 19th century, for example, there are said to have been many hundreds of unlicensed pawnshops in London. They made very small loans at very high rates of interest, without always taking in pledges. In Germany this type of business evaded legislation by assuming the form of resale, the debtor selling his pledge to the lender and repurchasing it after an interval at an enhanced price. In the late 1870s attempts were made by legislation to stop this practice by declaring that transactions of this nature fell under pawnbroking regulations. The Netherlands tried to meet an analogous need by setting up a special type of public institution prepared to make very small loans of short duration with a minimum of formalities.

HISTORY OF PAWNBROKING IN THE WEST

Pawnbroking in the west traces its origin to three different institutions which existed in the middle ages: private pawnbrokers, public pawnshops and *montes pietatis*.

Private Pawnbrokers.—The first person to satisfy the needs of his contemporaries for small consumption loans was the private pawnbroker. Usury laws in most countries prohibited the taking of interest. Pawnbroking was therefore carried on chiefly by classes exempt from these laws by religion or regulation, such as Jews and Lombards. The three golden balls, traditionally the pawnbroker's trade sign, once denoted the establishment of a Lombard merchant. In these transactions, the pledge represented legal evidence of debt, as is known from an Augsburg municipal law of 1276 regulating the trade of Jewish pawnbrokers. To the expansion of economic activity between the 12th and the 14th centuries corresponded a considerable increase in pawnbroking. Not only the poor and needy but also the well-to-do made use of pawnshops and were ready to pay rates of interest ranging up to 86% a year. Such rates were stigmatized as exorbitant exploitation and gave rise to periodic riots and violence against Jewish and other pawnbrokers. Attempts were made by public authorities to limit rates of interest. Florence in 1415 laid down a maximum rate of 15% but found control of transactions at that level impossible and had to raise it to 20% five years later. In another determined attempt the Florentine authorities in 1469 refused to renew the licences of moneylenders of any kind, but this merely drove intending borrowers to seek accommodation outside the town at rates of 30% or more. By this time the church was adapting its law to the realities of the secular world. While maintaining its prohibition against pure interest, it condoned remuneration given to lenders for damage suffered or profit forgone.

Public Pawnshops.—Much as public authorities deprecated the practices of private pawnbrokers, they realized the social need to which pawnshops ministered. Exploitation could be effectively prevented only by provision of alternative facilities for obtaining consumption loans, and as early as 1198, Freising, a town in Bavaria, set up a municipal bank which accepted pledges and made loans against moderate interest charges. Salins in Burgundy followed in 1350, and Michael of Northburgh, bishop of London, established a similar institution in 1361; municipal pawnshops were founded at Frankfurt am Main (1402), Florence (1473), Nürnberg (1498) and Augsburg (1591). In all these establishments charges in the form of limited interest or fees were levied merely with a view to covering costs; if profits were made, they went to public funds. However much they embodied a modern concept of social service, all these pawnshops enjoyed only a comparatively short existence; their moderate charges did not cover the risks incurred in this type of business.

Montes Pietatis.—Provision of social services in the middle ages was even more a task for the church than for public authorities. Canon law enjoined the faithful to refrain from usury, but the church saw the need for institutions to make lawful loans to indigent debtors. The Friars Minor (Franciscans) in Italy were the first to establish *montes pietatis* (*mons* denoted any form of capital accumulation), which were charitable funds to grant interest-free loans, secured by pledges, to the poor; the money was obtained from gifts or bequests. Barnabas, a Franciscan, raised the first *mons pietatis* at Perugia in 1462; others were founded at Turin (1519), Rome (1539), Bruges (1572) and Avignon (1577). Here again, the charitable intentions of the founders were frustrated by the economic difficulties. In order to prevent premature exhaustion of funds *montes pietatis* saw themselves compelled to charge interest, usually at rates between 4% and 12%, and to sell by auction any pledges which had become forfeit. These modifications raised the question of how far *montes pietatis* themselves offended against the usury laws. The fifth Lateran council in 1515 recognized *montes pietatis* as charitable institutions, and Pope Leo X issued a bull to this effect which authorized any charges necessary to cover expenditure. However, a number of these *montes*, especially that in Rome, developed into large-scale clerical banks, receiving deposits at interest and lending money to popes and foreign princes.

18th and 19th Centuries.—Many states reverted to public pawnshops as a means of preventing exploitation of the poor in the 18th century. The structure of national states had been sufficiently strengthened to bear the financial and administrative weight of institutions incurring considerable financial risks. Municipal establishments often enjoyed national backing, as for instance the Imperial Pawn office in Vienna, set up in 1713 with funds donated by Charles VI.

In Russia the mint made loans on gold and silver plate from 1733 onward, and state mortgage banks were authorized in 1754 to lend on the security of pledges. The Spanish Netherlands (the future Belgium) had a tradition of interlinked public pawnshops in the main towns going back to 1618, making loans at 15% or less, not only for public assistance but also on a commercial basis, and receiving deposits at 6¼%. A local pawnshop in Paris in 1777 was converted by Louis XVI into a municipal institution on the strong recommendation of Jacques Necker, the minister of finance, who wanted an instrument for fighting social unrest.

Public pawnshops everywhere suffered a decline toward the late 18th century because to the liberal thought of the period limitation of interest represented restriction, and the use of public funds stood for state monopoly. Thus, it was thought, trade would be prevented from finding its own level through the operation of free competition. The armies of revolutionary France carried this doctrine into practice wherever they went. Not only was complete freedom of trade in pawnbroking introduced in France, but in Italy and the Spanish Netherlands Napoleon confiscated as enemy property both the capital and the stock of pledges found in public pawnshops. However, France itself in 1804, and most of the other states as soon as they had freed themselves from French domination, reverted to a system of public pawnshops, having found complete freedom in this business harmful to debtors. The only state which made an attempt at a later date to reintroduce unrestricted pawnbroking, subject neither to licence nor limitation of interest rates, was Prussia where this system prevailed from 1869 to 1879.

At mid-20th century the public pawnshop predominated in the majority of countries on the European continent, sometimes alone, sometimes side by side with private pawnbrokers. A typical example was the Paris Municipal pawnshop, an establishment with

4 main and 22 subsidiary offices, employing a staff appointed by the state from candidates proposed by the municipality. Working capital was obtained through deposits, for which interest was paid at rates varying from 1% to 3%. Its profits, like those of other French municipal pawnshops, were applied to charitable purposes. On a similar scale was the Vienna Municipal pawnshop (known as the Dorotheum), which acquired 18 branches all over Austria by absorbing a large number of other Austrian municipal pawnshops unable in the 20th century to continue on their own.

MODERN CONDITIONS AND REGULATIONS

In a public pawnshop the problem arises how, in the absence of a profit motive, the institution is to be safeguarded against losses arising from overvaluing of pledges or default by borrowers. The modern solution is usually an appraisal of articles offered as pawns by assessors acting under oath; in some countries, assessors are held personally liable for any difference which arises between the valuation price and the proceeds of an eventual sale by public auction. This practice leads to deliberate undervaluation by assessors anxious to avert compensation claims. The loans granted may not exceed 75% to 80% of the assessed value plus the interest expected to accrue.

Europe.—Modern developments provided pawnshops with new tasks, and many institutions adapted their business methods to new requirements. The Monti di Pietà in Rome and Milan established physical laboratories, using the most modern techniques of radiography and microphotography, for determining and certifying the precious metal content of plate and other articles, whether submitted as pledges or merely to provide owners with an authoritative statement of their value. French municipal pawnshops accepted in pawn new merchandise which could be sold after three months if the borrower made a special request to this effect. From 1891 onward the Paris Municipal pawnshop accepted as pledges recognized stocks and bonds (as did the State Loan office in Berlin at most times in the 20th century) and after 1918 motorcars, with the result that its premises had to be expanded to include a huge garage. So reasonable are the charges of the Paris establishment that many well-to-do people prefer pawning their silver when leaving town for the summer to hiring the necessary space in a safe deposit. The practice of depositing valuables with the pawnbroker for this purpose is also known in Great Britain.

Great Britain.—In English-speaking countries exclusively, and in many other countries at least to some extent, pawnbroking is carried on by private individuals as a trade licensed and supervised by the authorities. The nature of this trade and the basis on which it operates may be treated in terms of the kind of goods that are pawned, the type of customer it attracts and the typical size of loan that is made.

In Great Britain between 60% and 75% of the number of pawnshops are engaged in the industrial trade; *i.e.*, three-quarters or more of their lending is advanced on "napery and drapery." The characteristic loan, in common with other prices, became higher in nominal terms after World War II. It did not, however, often exceed £2 and the characteristic sum was in the range of 10*s.* to 15*s.* In the city trade the situation is very different and the average loan much higher. The industrial pawnbroker makes some loans on jewelry, usually of relatively low value, and on a wide range of personal effects. There are also pawnbrokers who engage in a mixed trade, with a substantial proportion of pawnbroking of the nonindustrial kind.

Historically, the person who was the backbone of profitability in industrial pawnbroking in Great Britain was the habitual borrower. The basis of the trade in its heyday, from about the middle of the 19th century until 1913–14, consisted of a very large volume of pledging, backed by a very high rate of redemption and turnover. It is still typical of this trade, although on a reduced scale, that the regular pawner should bring in goods on Monday and Tuesday and redeem them on Friday or Saturday. Many articles which are eventually redeemed remain in pledge for considerably longer periods, but there is a large substratum of weekly trade. At the beginning of the week funds are raised; at the end of the week, when wages are received, goods are redeemed. There are also seasonal fluctuations; a great deal of clothing, for example, is redeemed just before bank holidays and pawned again after them. Investigations of German pawnbroking revealed a similar weekly periodicity with increases in business activity during the summer holiday season, just before quarter days and after holidays. Much pledging takes place at the time of the year when families stock up with fruit, potatoes and coal, whereas the beginning of wintry weather serves as a signal for much redemption of wearing apparel.

The fundamental attractions of pawning as a means of borrowing money, apart from any consideration as to the rates of interest which may be charged, are that sums may be raised on personal effects which might be less suitable as security in other forms of borrowing, and that these may be constantly "turned over" without final sacrifice of the article. The charges allowed to be imposed are limited in Great Britain by statutory regulation, namely, the acts of 1872 and 1922. The latter introduced only a quite minor modification in permitted charges.

No pawnbroker in Great Britain, however, confines himself to the business of pawnbroking strictly defined. There is always a section of his activity which is concerned with straightforward retail trade. This, in turn, tends to be of different types. Part of it consists in the sale of secondhand articles represented by forfeited pledges from the same pawnshop or bought at public auction of forfeits. Some will be the sale of new goods. In the industrial trade these are usually clothing and rather cheap personal effects; in the city and mixed trades, there is jewelry and a heterogeneous collection ranging from umbrellas to binoculars. In many cases the pawnbroker's retail interests developed independently and extensively so that the pawnbroking establishment became a minor appendage of the business as a whole. Indeed, the two sections have become entirely separated in some cases.

Since the charges which a pawnbroker may make are regulated, the absolute amount of his gross profit is determined by the volume of lending. This will be governed by the average size of the loan and the rate of turnover of monies lent; *i.e.*, the rate at which goods are redeemed. This involves the related point of the profit or loss which may accrue on articles sold after forfeiture. It is precisely because charges and average loans in the industrial trade, taken together, yield small absolute profits, particularly with charges remaining fixed in a world of rising money incomes and prices, that the basis of high profits would have to be a large volume of pledging coupled with a high rate of redemption of goods. The Hamburg, Ger., pawnshop, a municipal institution, investigated over a period the actual rate of redemption of all pledges received. It discovered that between 70% and 80% of all pawns were redeemed within the statutory time, though many not by the original borrowers but by purchasers of pawn tickets. For 15% to 20% of the pledges, an extension of the contract was arranged by mutual agreement. Less than 4% of the total stock of pawns was forfeited and subsequently sold by the pawnshop.

Regulation.—Pawnbroking has been among the most stringently regulated of trades. This regulation has rarely been completely abandoned, even when the general climate of the economy has been freest from the atmosphere of restriction. Apart from the influence of general policies, special reasons have been adduced for controlling this particular trade. Licensing and control of pawnbroking owe their origin to the desire to legislate against usury as such, to the fear that the pawnbroker might be a receiver of stolen goods and to an attempt to control interest rates in a sector where the customer was thought to be peculiarly susceptible to exploitation by virtue of his ignorance and poverty. Pawnbrokers themselves were acutely interested in regulation of the trade, both as regards reform of the hostile provisions included in the acts relating to it in Great Britain until 1872, and also perhaps in order to prevent the trade from being associated by public opinion with the dolly shop and similar institutions.

The national and local associations of pawnbrokers in the 19th century engaged in vigorous campaigns to gain support for legislation more favourable to their trade. It is interesting to note, however, that there was a division of opinion among pawnbrokers

between those who favoured freedom of trade and those who adhered to the view that regulation of charges was advisable. Changing economic conditions induced pawnbrokers to seek authority to make higher charges than those permitted by the act of 1872. A relatively small additional charge was authorized by an act of 1922. There was a good deal of discussion in the trade about the advisability of seeking further changes in the law relating to charges, particularly among industrial pawnbrokers.

Some amendments to the principal act of 1872 were in fact introduced by the Pawnbrokers Act of 1960 dealing with both loans and charges. The key figures for permitted loans under section 10 of the act of 1872 were 40*s*. and £10. These were amended by the new act to £5 and £50 respectively. These increased figures apply not only to loans but also to other sections of the 1872 act, such as section 6 (designed to prevent evasion), section 24 (dealing with special contracts) and part I of the 4th schedule, regulating pawnbrokers' profits. These were various provisions in the act of 1872 relating to forfeiture of pledges not redeemed in time, depending upon whether the loans were over or under 10*s*. This figure has been increased to 40*s*. The charges allowed to a pawnbroker for a pawn ticket, a valuation fee, inspection of an entry of sale in the sale book and for a declaration were also increased, but the sums involved were minimal and almost nominal.

The number of pawnshops in England and Wales was about 650 at the beginning of the 19th century. In 1848–49 there were 1,837 in Great Britain (England, Scotland and Wales). These figures exclude very substantial numbers of unlicensed establishments. The number of licences issued in 1913–14 (one per pawnshop) was 5,087, but a steady decline followed. The major decline was in the industrial trade; pawnbroking with a substantial element of city trade fared quite differently. Indeed, the characteristic features of the trade in the years since the 1920s have been the growth in relative importance of straightforward retailing and the fall in the share of industrial pawnbroking in the trade as a whole. The volume of pledge trade has fallen much more than the money value of pledges. The latter has been cushioned by rises in the amount of individual loans. Nevertheless, both volume and value are very much smaller than in, say, the 40 years preceding World War I. The decrease in the importance of pawnbroking in Great Britain is attributable to changes in both demand and supply conditions.

Demand Conditions.—Certain types of social policy helped to reduce the demand for loans by mitigating the effects of temporary interruption of earning power. Old-age pensions have probably been relatively unimportant because many of the recipients had few articles to pawn and little means of redeeming them. Family allowances, since they enabled beneficiaries to carry on until payday, are more likely to be significant. Slum clearing which removed former borrowers some distance from the pawnshop impaired the appeal of convenience and at least reduced the frequency of their visits to the pawnshop. Full employment and high wages, enabling young people to grow up in an environment removed from memories of unemployment, helped to break the traditional connection between the pawnshop and the poor.

Multiple (chain) stores selling relatively cheap clothing and other consumer goods may have further reduced demand for loans by enlarging opportunities for the easy acquisition of durable and semidurable consumer goods. Installment buying may have contributed further, although credit trading of various kinds was known long before the decline set in. There has been a change in consumer attitude, expressed in a strong disinclination to become involved in traditional modes of living by habitual pawning.

Supply Conditions.—Pawnbroking in the smaller industrial establishments is an arduous occupation. A suitable staff is hard to obtain, the more so because the trade is unpopular. All expenses have risen, while interest charges are held at the old levels. Returns do not compare favourably with what might be earned in straightforward retailing.

Since the trade attracts practically no new recruits, retirement or death of a pawnbroker usually means the disappearance of a pawnshop. Some pawnbrokers allow their pledge business to lapse and concentrate wholly on pure retailing; sometimes individual branches of multiple pawnshops close down. Some pawnbrokers persevere, however, from habit and attachment or because they are too old to move from what may be a fairly comfortable living. This tendency is strengthened by the fact that they might find it extremely difficult to dispose of their rather specific assets for an acceptable sum. (A. L. M.; W. M. Sn.; X.)

United States.—Although pledge borrowing existed earlier, pawnbroking became a recognized business in the United States during the 18th century and increased thereafter. New York city had 10 pawnbrokers in 1819, Boston more than 50 in 1859, Minneapolis 25 in 1893. Pawnshops probably reached a maximum by 1914 when they were the main source of consumer credit.

Pawnbrokers were regulated by states and municipalities practically from the beginning. New York in 1803 became the first state to authorize the licensing of pawnbrokers, while Pennsylvania in 1823 instituted general statutory regulation. State laws varied widely; some contained detailed provisions while others merely authorized municipal regulation. City ordinances required annual licences and fees of pawnbrokers, and frequently also required bonding. Ordinances often set maximum interest rates, forbade or limited other charges, fixed loan and redemption periods and required auction sale of unredeemed pledges and return of any surplus to pledgers. The police were to receive regular reports upon goods pledged.

Public and charitable pawnshops were proposed but were never established in the United States. Semicharitable lending agencies were created to make low-cost consumer loans on pledges, chattel mortgages, or both. These were the so-called remedial loan societies, organized as limited-dividend corporations. The first was the Collateral Loan Company of Boston, founded in 1859 as the Pawner's Bank. The largest was the Provident Loan Society of New York. Established in 1894, it developed numerous branch offices, charged 1% interest per month and became the world's largest pawnshop. By the 1930s it made more than 500,000 pledge loans each year, and in the 1950s it did over one-half of New York city's pawnbroking business. There were 38 "remedials" in 1915 and 27 in 1932, several having been abandoned but none organized after 1917. The Russell Sage foundation's Department of Remedial Loans, created in 1909, promoted remedials, cooperative credit unions and the enactment of small-loan legislation. Many states enacted its "uniform small-loan law," initially drafted in 1916, to encourage the commercial small-loan business.

"Remedials" and private pawnshops were overshadowed during the ensuing revolution in consumer credit. The new small-loan giants were sales finance companies, personal loan departments of commercial banks and private finance companies. Industrial banks, credit unions, credit jewelers, second-hand dealers and unlicensed "loan sharks" offered further competition to pawnbrokers. After 1945 discount houses cut into pawnbrokers' loan and sales departments, forcing lower loan valuations on pledges and lower prices in their retail trade. Pawnbroking declined rapidly after 1945; several cities lost one-third of their pawnshops within ten years. Many closed when their proprietors retired or died; others accentuated the retailing aspect of their business, or shifted entirely to retailing. New consumer credit agencies, discount houses, rising personal incomes, increased public-welfare measures and changed attitudes toward "hock shops" caused a rapid decline of pawnbroking.

PAWNEE, an Indian tribe on the Platte River, Nebraska, from before the 16th to the latter part of the 19th century. They

spoke a language of the Caddoan stock, and lived by farming and hunting, raising corn, squash, and beans, and hunting grazing animals, principally the bison. In their permanent villages they lived in large earth-covered lodges, but on bison hunts they used skin tepees. For hunting, travel, and transport they used horses first obtained in the 17th and 18th centuries from Spanish settlements in the southwest. In the 19th century the Pawnee tribe was composed of relatively independent bands—the Kitkehahki, Chaui, Pitahauerat, and Skidi—each divided into more or less endogamous villages with hereditary chiefs and priests. They had a Crow (lineage) type of kinship system, matrilineal descent and matrilocal residence after marriage, which was contracted for a given couple by their maternal uncles. Class distinctions favoured chiefs, priests, and shamans. The Pawnee religion was elaborate, including star symbolism and human captive sacrifice. Pawnee culture was broken by the start of the 20th century and the population reduced from about 10,000 to about 600. There were about 670 Pawnee reported living on or near their Oklahoma reservation in the 1960s.

See G. B. Grinnell, *Pawnee Hero Stories and Folk Tales* (1963), *Pawnee, Blackfoot and Cheyenne* (1961). (G. I. Qv.)

PAWPAW (*Asimina triloba*), a North American shrub or low tree of the custard apple family (Annonaceae), native from western New York to Nebraska and southward to Florida and Texas. The West Indian pawpaw is the papaya (*q.v.*). On rich alluvial soil the pawpaw grows from 10 to 50 ft. high, with large leaves, sometimes 12 in. long and 6 in. wide, and brown to dark red flowers 1 to 2 in. across. The fleshy fruits, two to five inches long, mature in autumn. Those with orange-coloured pulp are edible and possess a flavour reminiscent of the banana, while in contrast the pale white or yellowish pulps are usually bitter and unpalatable. These two types of fruit are known to legions of American boys who seek the edible forms each fall, yet no botanical distinction between the plants bearing them is made by taxonomists.

PAWTUCKET, a city of Providence County, Rhode Island, U.S., on the Blackstone River (known there as the Pawtucket or the Seekonk), is 4 mi. N of Providence and adjoins Central Falls. Pop. (1960) 81,001; Providence-Pawtucket standard metropolitan statistical area (as enlarged in 1963; *see* PROVIDENCE) 821,101.

The city lies on both sides of the river, which in the heart of the business district makes a picturesque plunge of 50 ft. over a mass of rocks. The name, Pawtucket, is an Indian word meaning "fall of the waters." At one time the river provided power for textile mills. Textiles have been the leading manufactured product for over a century. Almost every branch of the narrow fabric textile industry is represented. There are also plants for dyeing, finishing, and spinning. Other manufactures include wire and cable products, machine tools, and textile machinery.

The river was continuously improved by the federal government after 1867; there is a 16-ft. channel all the way to Narragansett Bay. A six-lane highway bridge over the river at Pawtucket was completed in 1958.

The first settlement within the present city limits was made on the west side of the river about 1671 by Joseph Jencks, an ironworker. His manufactory, destroyed in 1676 during King Philip's War, was rebuilt and soon the village became a centre for skilled and inventive ironmongers. In 1790, Samuel Slater found there the mechanical skill and financial support necessary to reproduce the Arkwright machinery for the manufacture of cotton goods. His mill, the first successful factory of its kind in the United States, was preserved as a memorial to the introduction of cotton textile manufacture.

The part of Pawtucket east of the river was originally in Massachusetts and was transferred to Rhode Island in 1862; the section west of the river was annexed to Pawtucket from North Providence in 1874; and in 1885 the town was chartered as a city. For comparative population figures *see* table in RHODE ISLAND: *Population.* (G. H. Bs.)

PAX, Roman personification of peace, probably recognized as a deity for the first time by Augustus, in whose reign much was made of the establishment of political calm. An altar of Pax Augusta was dedicated in 9 B.C. and a great temple of Pax completed by Vespasian in A.D. 75 (Platner-Ashby, *Topographical Dictionary*, s.v. *Pax, Ara Pacis*). (R. B. Ld.)

PAXOS (PAXOÍ), one of the Ionian Islands (*q.v.*) of Greece, about 8 mi. S of the south end of Corfu (Kérkira), is a hilly mass of limestone 5 mi. long by 2 mi. broad, and not more than 800 ft. high. Pop. (1961) 2,599. It produces excellent olive oil. Paxoí (formerly Gáïos), the principal village, lies on the east coast and has a small harbour. Toward the centre, on an eminence, stands Papándi, the residence of the bishop, and there are many churches with picturesque belfries. On the west and southwest coasts are remarkable caverns. Ancient writers apply the plural form Paxi to Paxos and the smaller island now known as Antipaxos or Andípaxoi (Propaxos of the *Antonine Itinerary*). Paxos is the scene of the legend, in Plutarch's *De defectu oraculorum* ("On the Cessation of Oracles"), of the cry "Pan is dead." *See* PAN. (W. G. F.)

PAXTON, SIR JOSEPH (1801–1865), English landscape gardener and designer of hothouses, turned architect when he designed the Crystal Palace which housed the Great Exhibition of 1851 in Hyde Park, London. Born near Woburn, Bedfordshire, on Aug. 3, 1801, he was originally a gardener employed by the duke of Devonshire and rose to be his friend, factotum, and adviser. From 1826 he was superintendent of the gardens at Chatsworth (*q.v.*), the duke's Derbyshire estate, and built for him in iron and glass the famous conservatory there (1837–40) and the lily house for the duke's rare Victoria Regia (1850). In the same year, when a cumbersome design (chosen from among many by professional architects) had already been officially accepted by the exhibition's organizers, Paxton's inspired plan for a building of prefabricated elements of sheet glass and iron was substituted. Covering four times the area of St. Peter's, Rome, the grandeur of its conception was a challenge to mid-19th-century technology. Built within six months, it was at once recognized as marking a revolution in style. In 1854 its components were moved to Sydenham where they remained (re-erected in a different form from the original) until accidentally destroyed by fire in 1936. Paxton was member of parliament for Coventry from 1854 until his death at Sydenham on June 8, 1865.

See Violet R. Markham, *Paxton and the Bachelor Duke* (1935).

PAYA, a tribe of Indians living in northeastern Honduras (*q.v.*), numbering fewer than 600 in the 1960s and dwindling rapidly. The linguistic relationship of the Paya is judged by some authorities to be Chibchan (*q.v.*). They practise slash-and-burn agriculture to raise manioc, maize, and pineapple. Some Paya subgroups are reported to allow polygyny. *See* also MIDDLE AMERICA: *Lower Central America.*

See P. Kirchhoff, "The Caribbean Lowland Tribes: the Mosquito, Sumo, Paya, and Jicaque," in J. H. Steward (ed.), *Handbook of South American Indians,* vol. 4 (1948).

PA-YI (PAI-YI, P'O-YI, PAI-I, PAVI), an ethnic group that is part of the greater Thai cultural group (*see* THAI PEOPLES). The Pa-yi inhabit the hot river valleys of southwest Yünnan Province in China. Having a preference for wet-rice culture, which does best in valleys near streams (*see* CHUANG), they spread southward from their cultural centres in Szechwan and the Yangtze Valley two millennia ago, following the southern tributaries of the Yangtze River into the Yünnan Lake basins. Under subsequent pressure of the Han Chinese (*see* CHINA: *The People*) the Pa-yi moved farther southwest into the river basins of the China-Burma frontier region. Those that settled across the border in the Shan plateau are called the Shan (*q.v.*) tribes of Burma. Uncomfortable climate, malaria, and primitive living conditions long discouraged the Han Chinese from settling in Pa-yi territory. Thus, although the Pa-yi in Yünnan were compelled to acknowledge Chinese suzerainty, largely they were left to the rule of their own hereditary local chieftains. Many of these petty despots retained virtual autonomy in local affairs until after the Communist conquest of mainland China. Following this the Pa-yi were organized into a Thai Autonomous District (population about 470,000 in the 1960s) by the Communist regime. The social and economic systems of the Pa-yi also changed to conform with Communist ideology.

PAYMENT is the performance of an obligation to pay money. A person under such an obligation is called a debtor and a person to whom the obligation is owed is called a creditor. The obligation may arise in various ways, but most commonly as the result of a contract between the parties. In law, in order that payment may extinguish the obligation, it is necessary that it be made at a proper time and place, in a proper manner, and by and to a proper person.

England and Wales.—Payment may be made at any time of the day on which it falls due, except in the case of mercantile contracts, where payment must be made during the usual hours of mercantile business. In the absence of any agreement as to the place of payment, it is the duty of the debtor to take reasonable steps to seek out his creditor and to pay him the money, provided that the creditor is in England. A debtor is not, without agreement, entitled to any notice or demand from his creditor.

Payment must be made in lawful money, frequently referred to as legal tender. Gold is legal tender up to any amount, as are Bank of England notes. Silver or cupronickel is legal tender up to 40 shillings' worth and bronze up to one shilling's worth. A debtor has no right to demand change. The parties may, however, agree that payment shall be made in some other way; for example, by bill of exchange, by promissory note, or by check (all of which are commonly called negotiable instruments). Where payment is made by negotiable instrument, the general rule is that the acceptance of such instrument by the creditor operates only as a conditional payment. This means that if the instrument is subsequently dishonoured the debt revives, and the creditor may sue either on the instrument or on the original debt. The parties may however agree that acceptance of a negotiable instrument shall operate as an absolute payment, in which case, if the instrument is dishonoured, the creditor may sue on the instrument but not on the original debt. A payment may be made by the mere transfer of figures in an account without any money changing hands. If goods are accepted in satisfaction of a debt this constitutes payment.

When a debtor makes payment by post, and the money or instrument is lost in the post without fault on the part of the debtor, the debtor will have to bear the loss; unless the creditor directed payment by post, or unless payment by post was the usual way of business between the parties, in which cases the loss will be on the creditor. Payment may be made by a debtor personally or by a duly authorized agent on his behalf. Similarly, payment may be made to the creditor personally or to an agent of the creditor, provided that such agent has authority to receive payment. The general rule is that payment of a debt cannot be enforced after a lapse of six years.

A common way of proving payment is by the production of a signed receipt. But payment can be proved in other ways and, conversely, production of a receipt is not conclusive evidence of payment. The payee of money is liable to a penalty if, in any case where a receipt would be liable to duty, he refuses to give a receipt duly stamped and canceled.

Money paid under a mistake of fact can be recovered, but not money paid under a mistake of law.

(For appropriation of payments, *see* DEBTOR AND CREDITOR LAW. *See* also LIMITATION, STATUTES OF.)

Scotland.—The law of Scotland is substantially the same as that of England, differing therefrom only in the following respects. Bank notes issued by a bank of issue in Scotland are legal tender to any amount. The general rule is that payment of a debt cannot be enforced after 20 years, and it may be that money paid under a mistake of law is as much recoverable as money paid under a mistake of fact. The main point of difference between the two systems, however, is that in Scotland there are special rules relating to the manner in which a debt may be proved; and, in particular, there is a rule that if a document of debt is in the hands of the debtor there is a presumption that the debt has been paid.

United States.—In the United States the position is much the same as in the United Kingdom. The duty of the debtor to seek out his creditor obliges him to search only in the creditor's state of residence. If the creditor cannot be found therein there is no obligation upon the debtor to look further. In a few states money paid under a mistake of law can, in some circumstances, be recovered. The question of legal tender has been an important one in U.S. history. In 1862 and 1863 Congress passed acts making treasury notes legal tender (*see* GREENBACKS). After much litigation the Supreme Court decided in 1871 in favour of the constitutionality of these acts. These notes were held to be legal tender for all purposes except duties on imports and interest on the public debt. In 1933 all coins and currencies of the United States were made legal tender for all debts, public and private (including import duties and interest on the public debt). By the Constitution of the United States, "No State shall . . . make any Thing but gold and silver Coin a Tender in Payment of Debts" (Art. I, sec. 10). The law relating to limitation is complex and varies from state to state. (H. W. B.)

PAYNE, JOHN HOWARD (1791–1852), U.S. playwright and actor, one of the most notable of the school of American playwrights that followed the techniques and themes of the European romantic blank verse dramatists, was born in New York City, June 9, 1791. A precocious actor and writer, he wrote his first play, *Julia, or, The Wanderer*, when he was 15. The play was successful enough to cause him to be sent to Union College, Schenectady, N.Y., but family financial difficulties made it necessary for him to leave two years later. At the age of 18 he made his first stage appearance in the play traditional for such debuts, John Home's *Douglas*. Although his portrayal of Young Norval was successful, Payne encountered much opposition from established actors—chiefly George Frederick Cooke, a brilliant but eccentric star—and in 1813, at the height of the War of 1812, Payne sailed for England. At first interned as an enemy national, he was later released and triumphed at Drury Lane as Young Norval, repeating his success in other European capitals. In Paris, Payne met two men who were to have an important influence on his career: the actor Talma, who introduced him to French drama, from which many of his more than 60 plays were adapted; and Washington Irving, with whom he was to collaborate on two of his best plays.

Payne's finest play, *Brutus; or, The Fall of Tarquin*, was produced at Drury Lane on Dec. 3, 1818. Although Payne received only £183 for it, *Brutus* was on the boards for 70 years and served as a vehicle for three of the greatest tragedians of the 19th century: Edwin Booth, Edwin Forrest, and Edmund Kean. Other important plays were *Clari: or, The Maid of Milan*, which included Payne's famous song "Home, Sweet Home"; *Charles II* (1824), written with Irving; and *Thérèse* (1821), a French adaptation. Because of weak copyright laws, Payne received little return from his successful plays, and in 1842 he accepted a consular post in Tunis, where he died, April 9, 1852.

Although Payne was no innovator, his plays were strong, both in language and structure, and he exerted an important influence on later playwrights. Arthur Hobson Quinn suggests that *Brutus* may have been partially responsible for the emergence of the romantic drama in France under Hugo. (S. W. H.)

PAYNE, PETER (*c.* 1380–1456), English Lollard and Hussite diplomat who rendered great service to the Bohemian Hussite movement. Born at Hough near Grantham, he was a master of arts at Oxford by 1406, where he was principal of St. Edmund Hall during 1410–12, at about which time he joined the Lollard movement.

The Lollard Sir John Oldcastle's fall from power forced Payne, in 1413, to flee to Bohemia, where by 1415 he was defending Utraquism beside Jakoubek of Stribro. Huss's successor (*see* HUSSITES). During the subsequent revolution he was a leading figure in the consistory which governed the Hussite Church and was entrusted with several important missions. In 1420 he accompanied the Prague mission to the Polish court, and, respected alike by both the Taborite and "Orphan" Hussite sects, he was able to speak for the whole Hussite movement before King Sigismund at Bratislava in 1429, when he splendidly defended the Hussite program, the "Four Articles of Prague." After returning to Poland in 1431 he also gave notable service at the Council of

Basel in 1433, when he was entrusted with the defense of the expropriation of church property. Taken prisoner at the Battle of Lipany in 1434, he was soon freed, and took further part in the peace negotiations in the provincial Diet, but was expelled from Prague shortly after the signing of the peace and the return of Sigismund. He was arrested and imprisoned for two years by his enemies, but was ransomed by his friends from Tabor.

When negotiations began in 1441 for the unification of the Hussite Church under the elected archbishop, Jan Rokycana, Payne worked hard but unavailingly for agreement between Rokycana and the Taborites. Returning in 1448 to Prague, where the Rokycana Party was now established, he lived there till 1456, in the Na Slovanech monastery. Though he remained a foreigner in Prague, and never learned Czech, Payne gave the Hussites invaluable service both as diplomat and as theologian, and is gratefully remembered in the country of his exile.

BIBLIOGRAPHY.—Payne's literary works are listed in F. M. Bartoš, *Literarni činnost M. J. Rokýcany . . . a P. Payna* (1928). *See* also four orations ed. by F. M. Bartoš, *P. Payne, Pro Bohemis* (1949); A. B. Emden, *An Oxford Hall in Medieval Times* (1927). (F. M. BA.)

PAYSANDÚ, a department of western Uruguay, bordering the Uruguay River. Although the riverside and hinterland areas of Paysandú were developing agriculturally in the second half of the 20th century, ranching continued to be the department's major activity. Cattle and sheep are raised, and agricultural products include flax, wheat, sunflower seeds, corn, and forage crops. Surrounding farms supply vegetables and poultry to the departmental capital, Paysandú (*q.v.*). Several foreign agricultural colonies were notably successful, especially in southwest Paysandú. Area of the department 5,474 sq.mi. (17,959 sq.km.); pop. (1962 est.) 103,111. (M. I. V.)

PAYSANDÚ, a city and port of western Uruguay on the Uruguay River, is 300 mi. NW of Montevideo. Capital of the department of Paysandú (*q.v.*), it disputed with its rival to the north, Salto, the claim of being Uruguay's second largest city. One advantage of Paysandú (pop. [1962 est.] 56,080) over Salto, also a river port, is that oceangoing ships must transfer cargo at Paysandú to smaller craft because farther north the Uruguay River becomes too shallow for the draft of the larger vessels. Cereals, flax, and livestock products are loaded and merchandise for northwest Uruguay is unloaded at the port of Paysandú; it is built at various levels so that ships can dock despite changes in the level of the river. There are rail, road, and air connections to the north and southwest to Montevideo.

Paysandú has a relatively varied industrial economy with tanneries, textile factories, flour mills, distilleries, and breweries processing regionally produced raw materials. In the second half of the 20th century, modern buildings were changing Paysandú's once provincial aspect.

The city was founded in 1772 by Father Policarpo Sandú and 12 families of Christianized Indians. Indians translated the Spanish word *padre* ("father") into the Guarani Indian dialect word *pay*, from which stems the city's name. (M. I. V.)

PAZ ESTENSSORO, VÍCTOR (1907–), founder and principal leader of the Bolivian political party Movimiento Nacionalista Revolucionario (MNR), served as president of Bolivia from 1952 to 1956 and again after 1960. His administration marked the beginning of a process of revolutionary change in Bolivia's social, economic, and political structure.

Paz Estenssoro was born in Tarija in 1907. He obtained a university education, served in the army during the Chaco War with Paraguay (1932–35) and after the war became professor of economics at the University of San Andrés in La Paz. He was economic adviser to Pres. Germán Busch (1937–39) and in 1939 was elected to the Chamber of Deputies.

In 1941 Paz Estenssoro and others established the MNR, a left-wing nationalist party that sought to advance the interests of the Indians. After the party seized power in 1952 Paz Estenssoro became president. During his administration the right to vote was extended to the Indians, and the three largest tin companies were expropriated by the government. Most fundamental of all, an agrarian reform law began the process of transferring the arable land of the central plateau to the Indians.

During the administration of Hernán Siles Zuazo (1956–60) Paz Estenssoro served as ambassador to the United Kingdom. He again became the MNR candidate for president in 1960 and won a decisive victory. During his second administration his government reached an agreement with the U.S. government, the Inter-American Development Bank, and West German industrialists, providing for a reorganization of the tin-mining industry. He also stressed a program to stimulate colonization of eastern Bolivia by Indians from the highlands.

Over the protests of the opposition parties and some leaders of the MNR, Paz Estenssoro again ran for president in 1964. All other parties withdrew their candidates and urged the voters to boycott the election. About 70% of the eligible voters cast their ballots for Paz Estenssoro. Nevertheless, he was overthrown by a military *coup d'état*, headed by Vice President René Barrientos Ortuño in early November 1964 and went into exile in Peru.

(R. J. A.)

PAZ SOLDÁN, MARIANO FELIPE (1821–1886), Peruvian historian and geographer, was born at Arequipa, on Aug. 22, 1821. He studied law, and after holding some minor judicial offices, was minister to New Granada in 1853. In 1860 Castilla made him director of public works. In 1861 he published his great atlas of the republic of Peru, and in 1868 the first volume of his history of Peru after the acquisition of its independence. A second volume followed, and a third, bringing the history down to 1839, was published after his death by his son. In 1870 he was minister of justice and worship under President Balta, but shortly afterward retired from public life to devote himself to his great geographical dictionary of Peru, which was published in 1877. During the disastrous war with Chile he sought refuge at Buenos Aires, where he was made professor in the National College, and where he wrote and published a history of the war, *Historia de la Guerra del Pacifico* (1884).

He died at Lima on Dec. 31, 1886.

PEA, the common name for several species of herbaceous annuals of the family Leguminosae, grown for their edible seeds, borne in pods, or legumes. The favourite market and garden pea in North America, Europe, and parts of Asia is a variety of *Pisum sativum*. As is true of most food plants, the origin of the pea is prehistoric. It appears to have originated in Middle Asia, with secondary centres in the Near East, in Ethiopia, and in Mediterranean lands. Remains of the seeds have been found on the sites of Swiss lake-dwellings of the Bronze Age, dating back perhaps 5,000 years. The two main varieties of *P. sativum* are *humile* (or *hortense*), the choice dwarf garden pea (about two feet tall), and *arvense*, the taller (up to six feet) field pea. The dwarf pea, in its many horticultural forms, is widely grown for food; the field pea is grown chiefly for dried peas, forage, and green manure.

J. HORACE MCFARLAND CO.

GARDEN PEAS (PISUM SATIVUM)

The stems of the pea plant are hollow, and trailing or climbing. Leaves are pinnately compound, ending in tendrils that enable the plant to climb, and with large leafy stipules at their bases. The flowers are papilionaceous, or butterflylike, white or purple, about one inch across; each has nine united stamens and one free stamen; the single pistil has a bearded style. Flowers are self-pollinated, and nectar is secreted at the base of the stamens. The fruit is a characteristic legume, a one-celled, many-seeded pod, 2½–5 in. long, which splits into halves when ripe; the five to ten seeds are attached by short stalks to the halves of the pod. The seeds are more or less globular and smooth, dimpled, or wrinkled. Ripe seeds of white-flowered forms are cream, yellow, or light green; in purple-flowered forms they

are brown, gray, or flecked with dark colour. The cotyledons are large and roughly hemispherical. Upon germination and emergence of the seedling the cotyledons remain below the soil surface.

Some varieties, called sugar peas, produce pods that are edible; before the seeds enlarge appreciably the flat pods are tender, succulent, and sweet. This type of pea is popular in the Orient. Wrinkled seeded varieties are usually sweeter than smooth and dimpled varieties because they contain more sugar and less starch. Split peas for soup consist of only the cotyledons of smooth peas harvested mature dry.

The garden and field peas will tolerate a considerable range of climatic conditions but do not grow well in hot climates. Peas can be grown in the lower latitudes (such as the southern United States) only as late fall, winter, or early spring crops. The plants will tolerate some frost but not hard freezing.

Spring sowings in the United States are normally made about a month to six weeks before the average date of the last freeze and are finished before the frost-free date. Peas grow on a wide range of soils, but the soil preferably should be rich, well drained, well limed, well prepared and kept free of weeds. Inoculation of the seed with pure cultures of nitrogen-fixing bacteria is a generally profitable and common practice in certain parts of the U.S. and in northern Europe but is not normally necessary in Britain. In many pea-growing districts of the United States the soils have become so infested with a wilt fungus that only wilt-resistant varieties can be grown successfully. Under good farming practice, peas are not grown on the same land more than once in four years. In Great Britain early peas can be grown from November onward through the winter, but such methods are not used in America, where fall and winter sowings are made far enough south so that hard freezing rarely occurs.

For home garden and marketing fresh, either dwarf or tall-vined, large-podded sorts are sown in rows two to four feet apart, depending on the variety. One to two bushels of seed per acre are sown. When grown for home or fresh market, the tall varieties are usually supported on twigs or brush, or on light trellises of twine, but this is not done for a large commercial planting. Peas for canning or freezing are sown in rows six or seven inches apart, at the rate of about four bushels of seed per acre. Since they are not cultivated or hoed, the soil must be thoroughly prepared and comparatively free from weeds. These peas are sown with a grain drill and harvested with a mowing machine or special pea harvester, and the entire plants are then passed through a "viner"—a machine that removes the peas from the pods and separates them from all leaves and debris. The shelled peas are hauled to the processing plant and canned or frozen within a few hours. Field or harvest peas are for use dry and are also sown in rows six or seven inches apart. The entire plants are harvested before the seeds shatter from the dry pods, and they are allowed to dry in small shocks or windrows in the field; then threshed and cleaned —all by machinery.

The genus *Pisum* is very closely related to *Lathyrus*, which is distinguished botanically from *Pisum* by its flattened rather than tubular style. It is therefore not surprising that some species of *Lathyrus* are called peas. The fragrant ornamental sweet pea is *L. odoratus* and the Tangier pea is *L. tingitanus*. Many other legumes that are less closely related to *Pisum* also are called peas of various kinds, among them: the chick-pea, *garbanzo* or Spanish pea (*Cicer arietinum*), the cowpea (*Vigna sinensis; see* BEAN), and pigeon pea (*Cajanus indicus*).

Production.—In the United States, peas are no longer grown extensively for marketing in the pod because of the high cost of harvest by hand and competition from the quick-frozen and canned products. Dry peas and canned peas each account for over 35% of the acreage, while frozen peas account for over 20%. In Great Britain the acreage of peas marketed in the pod has rapidly declined and the acreage of peas harvested dry for processing is falling sharply. The growing acreage of peas raised for frozen-food manufacturers surpasses that for podded peas, though canned garden and canned process peas together account for the largest share of the pea market. In northern Europe canned garden peas, particularly the "petit pois" type, are the most popular, but quick-frozen peas are becoming more available. In southern Europe, peas are still widely grown for marketing in the pod. Green peas for processing, both canned and quick-frozen, are also grown in Australia and New Zealand. (V. R. B.; J. W. Bu.)

PEABODY, ELIZABETH PALMER (1804–1894), U.S. educationist and participant in the Transcendental movement, was born at Billerica, Mass., on May 16, 1804. Educated at a small private school by her gifted mother, as were her sisters Sophia (Mrs. Nathaniel Hawthorne) and Mary (Mrs. Horace Mann), she began her own teaching at 16. Later she was an assistant in A. Bronson Alcott's famous Temple School, of which she published a *Record* (1835). Although overshadowed by Margaret Fuller, she was one of the leading feminine figures in the Transcendental movement, her West Street bookshop becoming a sort of club. In 1860 Miss Peabody opened in Boston the first kindergarten in America. She went to Europe in 1867 to study Friedrich Froebel's methods at first hand, and thereafter through training classes, lectures, magazine contributions, and her editing of the *Kindergarten Messenger* (1873–77) she spread the new theories. Her writing reflects her dominant interests. She died at Jamaica Plain, Mass., on Jan. 3, 1894.

PEABODY, a city of Essex County, Mass., 13 mi. NE of Boston. The area that now constitutes Peabody was originally part of Salem (*q.v.*) then part of Danvers (*q.v.*) when that community was separated as a district from Salem in 1752. South Danvers became a town in 1855 and in 1868 adopted the name of Peabody to honour George Peabody, the philanthropist who was born and buried there. In 1882 part of Peabody was annexed to Salem. In 1916 Peabody was incorporated as a city. It is a manufacturing centre for leather, shoes, and cotton goods. In the early 1900s a number of immigrants, largely from Greece, Ireland, Russia, and Poland, settled there. For comparative population figures *see* table in MASSACHUSETTS: *Population.* (J. F. Co.)

PEACE, CHARLES FREDERICK (1832–1879), English murderer and cat burglar to whom legendary exploits have been ascribed, was born in Sheffield, Yorkshire, on May 14, 1832. After a successful career of robbery, he shot and killed a man named Arthur Dyson in the Sheffield suburb of Eccleshall in 1876 during a quarrel over Dyson's wife. He escaped the police by assuming another identity and for nearly two years lived, as "a gentleman of independent means," at Peckham in London; at night he committed widespread burglaries which entirely baffled the police. While attempting one of these in October 1878 he was arrested, almost by accident, in the London suburb of Blackheath. Only later was he charged with the murder of Dyson, for which he was executed at Leeds on Feb. 25, 1879.

See R. W. Postgate, *Murder, Piracy and Treason* (1925); W. T. Shore (ed.), *Trial of Charles Frederick Peace* (1926); D. Ward, *King of the Lags* (1963). (R. W. P.)

PEACE, INTERNATIONAL. Since the beginning of history, peace has been regarded as a blessing and its opposite, war, as a scourge. Yet it is only since the end of the Middle Ages that philosophers and statesmen have reflected systematically on the problem of peace. Attempts to put international peace on a secure basis on a worldwide scale through deliberate political action had to wait until the beginning of the 19th century.

Both movements, the speculative and the practical, were stimulated by political catastrophes that demonstrated the urgent need for making international peace secure. Men started to speculate about new forms of international organization after the rise of the territorial state had deprived the Holy Roman Empire of its political functions as the international organization of Christendom. Where could a substitute for this lost political unity, safeguarding at least a modicum of peace and order, be found? This question was posed by Erasmus in the 16th century, by Sully, Émeric Crucé, Hugo Grotius, and William Penn in the 17th, and by the Abbé de St. Pierre, Jean Jacques Rousseau, Jeremy Bentham, and Immanuel Kant in the 18th. Their answers were generally couched in terms of international law or of an international organization based upon international law.

The political measures of modern times to make international peace more secure had their starting point in the experience of

the Napoleonic Wars. That experience had a dual impact upon the international order of the modern world. The Napoleonic Wars destroyed the balance of power that had been the foundation of international peace and order since the end of the Middle Ages and threatened to replace it with a universal empire which, while it might assure peace temporarily, might destroy freedom forever. They also brought to victory the idea of nationalism that threatened to destroy the old dynastic order and to usher in an unending series of international crises and wars.

To these political factors that stimulated the search for a practical solution to the problem of international peace must be added three others: spiritual, moral, and intellectual.

From the time of the Stoics and the early Christians there has been present in Western civilization a feeling for the spiritual unity of the Western world which, in order to realize itself, is in need of a political organization commensurate with it. The Roman Empire was such a political organization of universal scope. It remained throughout the history of the Western world a symbol of its spiritual unity, which inspired Charlemagne no less than Napoleon and which provided throughout the Middle Ages the ultimate justification for the policies of the Holy Roman Empire and of the papacy. Thus it is not surprising that at the very moment the Holy Roman Empire was dissolved in 1806, Napoleon tried to revive it, and that only a decade later statesmen made attempts to find a substitute for the international order that the Holy Roman Empire had sought to provide.

The moral root of modern attempts to find a stable foundation for international peace must be sought in the increased humaneness and civilized conduct, of which the great political and social reforms of the 19th and 20th centuries are the outstanding practical realization. Religion, the philosophy of the Enlightenment, and the political theory of liberalism all postulate respect for human life and the promotion of human welfare. To extend the reign of law, peace, and order from the domestic to the international sphere was a logical conclusion from these postulates.

The intellectual factor underlying this development is to be found in the rise of the commercial and scientific spirit in the 18th and 19th centuries. To that spirit war is an irrational disturbance of the rational order of things. According to Kant "the commercial spirit cannot co-exist with war." Similarly, Herbert Spencer believed that war had become obsolete in an industrial society. Thus it was widely believed that permanent peace on the international scene could be established through the same concerted rational effort that seemed to have brought such spectacular benefits to mankind in other fields.

The convergence of these four factors at the beginning of the 19th century initiated the practical search for alternatives to war and sustained it thereafter. This search for permanent peace has been carried on through three different mediums: (1) limitation of the destructive and anarchical tendencies of international politics; (2) transformation of international politics by eliminating its destructive and anarchical tendencies altogether; and (3) accommodation of divergent interests by depriving the destructive and anarchical tendencies of international politics of their rational objectives.

To establish peace through limitation several devices have been used: disarmament, collective security, judicial agencies, peaceful change, international government. Peace through transformation has been sought through the establishment of a world state. Diplomacy has served the purposes of peace through accommodation.

Disarmament.—This term denotes the reduction or elimination of certain or all armaments for the purpose of stopping the armaments race. Disarmament must be distinguished from arms control, which seeks military stability through mutual deterrence in preparation for actual disarmament. Furthermore, general disarmament must be distinguished from local disarmament, and quantitative from qualitative disarmament. (*See* DISARMAMENT.)

General disarmament refers to a kind of disarmament in which all the nations concerned participate: examples are the Washington Treaty for the Limitation of Naval Armament of 1922, signed by all major naval powers, and the World Disarmament Conference of 1932 in which virtually all members of the community of nations participated. We speak of local disarmament when only a limited number of nations are involved; the Rush-Bagot Agreement of 1817 between the U.S. and Canada exemplifies this type.

Quantitative disarmament envisages an overall reduction of armaments of most or all types, as did the World Disarmament Conference of 1932. Qualitative disarmament aims at the reduction or abolition of certain types of armaments only, such as atomic weapons.

The first modern attempt at disarmament occurred in 1816 when the tsar of Russia proposed to the British government the "simultaneous reduction of the armed forces of every kind." Many similar proposals throughout the 19th century, especially by France, culminated in the Hague Peace Conferences of 1899 and 1907, both of which passed resolutions affirming the desirability of the restriction of armaments. It must be noted that most of the attempts at securing international peace through disarmament failed and that the two which succeeded, the Rush-Bagot Agreement of 1817 and the Washington Treaty for the Limitation of Naval Armaments of 1922, were an integral part of a political settlement which carried in itself the assurance of peace. In other words, as the armaments race is a symptom of political conflict which is likely to lead to war, so is disarmament the symptom of the disappearance of political tension which by itself gives assurance for the preservation of peace. Disarmament by itself, especially if it is of the local and qualitative type, gives no such assurance, for at best it would be able to alter the methods by which war is to be waged (but not the incidence of war itself).

Collective Security.—The concept of collective security assumes that nations generally increase their armaments and go to war either because they are in fear of aggression or because they trust that aggression will succeed without too great a risk. If the community of nations could provide its members with security through collective action, the main motive for war would disappear. In a system of collective security, security is the concern of all nations which will take care collectively of the security of each of them as though their own security were at stake. If nation A threatens nation B's security, C, D, E, F, and G will take measures on behalf of B and against A as though A threatened them, and vice versa.

The ability of a system of collective security to preserve peace rests on three assumptions: (1) the collective system must have at its disposal at all times sufficient strength to deter any potential aggressor; (2) the nations which dispose of such overwhelming strength must have the same interest in defending the status quo; (3) these nations must subordinate their conflicting political interests to the overriding concern for collective defense. The history of collective security, as it was provided for by the Covenant of the League of Nations and the Charter of the United Nations, shows that these three conditions are rarely present at the same time. First of all, history shows that aggression is generally threatened or committed not by one but several nations which, at least initially, are of approximately equal if not superior strength to those who are willing to resist aggression. The reason for this state of affairs must be sought in the fact that what is required for the security of one group of nations may be incompatible with, or actually threaten the security of, another group of nations. Finally, collective security presupposes a moral transformation which makes individual nations forego their national egotisms and the national policies serving them for the sake of collective policies serving the supranational purpose. (*See* also SANCTION AND GUARANTEE.)

Judicial Agencies.—Among other means that have been devised to preserve peace on the assumption that international conflicts have led to war because there were no facilities available to nations to settle their conflicts peaceably are judicial agencies. Nation A wants something of nation B which nation B is not willing to concede. Hence, A will try to get what it wants from B by force of arms. If there were a method, acceptable to A and B and fashioned after the model of national judicial agencies, of settling that conflict peaceably, war would become superfluous as the supreme arbiter among nations.

Thus during the second half of the 19th century the arbitration movement gained strong popular support for proposals to establish international arbitration courts with compulsory jurisdiction to settle all international conflicts. Many nations concluded treaties for the judicial settlement of at least certain types of disputes. The movement culminated in the establishment of the Permanent Court of Arbitration by the Hague Convention for the Pacific Settlement of International Disputes of 1899 and 1907, of the Permanent Court of International Justice in 1919, and of the International Court of Justice in 1946.

However, none of the disputes settled by these courts can be said to have carried the risk of war had it not been settled by an international tribunal. Furthermore, all nations likely to get involved in political disputes of a serious nature were careful to circumscribe strictly the type of dispute they were willing to submit to judicial settlement. Only nations which were unlikely to get involved with each other in disputes of this kind, such as Colombia and El Salvador, Denmark and Portugal, the Netherlands and China, Belgium and Sweden, agreed to submit all disputes to arise between them to judicial settlement without any qualification. Finally, and most importantly, while disputes between two individuals to be submitted to a national court concern the application or interpretation of the law as it is, disputes between states which are likely to lead to war typically have as their object the very survival of the legal order, which one state wants to change in opposition to another defending it. Issues of this kind, however, are of a legislative nature, and judicial agencies are unable to cope with them.

Peaceful Change.—The issue of peaceful change is raised by the inability of judicial agencies to settle peacefully disputes that concern not the application of the existing legal order, but its transformation. National societies, especially those of a democratic character, are continually engaged in processes of peaceful change. These processes are made possible by three factors: (1) the ability of different trends in public opinion to express themselves freely and compete with each other for maintenance or change of the status quo; (2) the ability of social and political institutions to absorb the pressures of public opinion and to translate them into legal measures and institutions; (3) the ability of the state to protect the result of these competing social pressures against violent change.

These factors are largely absent on the international scene. No free interplay of different trends in public opinion exists to the same extent between nations as it does within them. International social and political institutions are of a rudimentary character; more particularly, the operation of international legislative bodies, making majority decisions with binding effect upon the minority, is precluded by the principle of sovereignty, at least for matters of a political nature. For the same reason there can be no supranational organization of compulsion that is not based upon the voluntary cooperation of individual states.

In consequence, the institutional devices introduced into the Covenant of the League of Nations and the Charter of the United Nations in order to facilitate peaceful change proved to be ineffectual. Article 19 of the League Covenant reads: "The Assembly may from time to time advise the reconsideration by Members of the League of treaties which have become inapplicable and the consideration of international conditions whose continuance might endanger the peace of the world." Article 14 of the UN Charter refers in general to "the peaceful adjustment of any situation, regardless of origin, which it (the General Assembly) deems likely to impair the general welfare or friendly relations among nations." Article 19 of the Covenant was formally invoked only once, by Bolivia against Chile in 1920, but was not acted upon because Bolivia retracted its request. It was further weakened by authoritative interpretation of the assembly. The General Assembly of the United Nations made recommendations for peaceful change in a number of cases, such as the treatment of Indians in South Africa, the situations in Greece and Korea, the problems of Spain and Palestine, and the disposition of the former Italian colonies of Libya, Eritrea, and Somaliland. Of these attempts at peaceful change, only the latter two were genuine and successful. Yet the actual partition of Palestine was the result of a war between the Arab nations and the Israelis, a fact which the UN General Assembly had to recognize in succeeding recommendations.

Peaceful change administered by an international organization comes up against a basic fact of international life: national sovereignty. If the international organization respects national sovereignty and, hence, only recommends peaceful change, the effectiveness of the recommendation will depend upon the agreement of the parties concerned; yet if the parties concerned agree anyway, the recommendation is at best not a decisive factor and at worst superfluous. If the parties do not agree, change must then be imposed upon them by the international organization and will be peaceful only if it can be imposed under the ideal conditions—hardly attainable, as we have seen—of collective security.

International Government.—The above-mentioned devices to establish international peace are intended to provide specific remedies for particular problems. International government, on the other hand, recognizes that peace and order can be secure only in an integrated society existing under a common authority and a common conception of justice. International government, then, is the attempt to establish such an authority and to create such a conception of justice in a society of sovereign states. Such an attempt followed each of the three world wars of the 19th and first half of the 20th century. The Napoleonic Wars called into being the Holy Alliance; World War I the League of Nations; and World War II the United Nations. None of these international organizations was able to put international peace on a more secure basis for identical reasons, inherent in the nature of international government.

The Holy Alliance, the League of Nations, and the United Nations were conceived as international governments by the great powers; this is obvious from the membership of the Holy Alliance as well as from the membership and the functions of the council of the League of Nations and the Security Council of the United Nations. The ability of these international organizations to protect the peace of the world, then, depended upon the ability of the great powers to work in unison for the achievement of that objective. Yet in all three organizations the particular interests of individual great powers prevailed over the interest they were supposed to have in common: the preservation of peace.

All three organizations had as their basic political objective the maintenance of the status quo as it had been established by the preceding world war. However, not all the great nations had the same understanding as to what the maintenance of the status quo meant in view of their particular interests, nor were all of them equally interested in the maintenance of that status quo. Thus it came about that first the usefulness and then the very existence of the Holy Alliance was destroyed by the conflict between Great Britain and Russia, which lasted throughout the better part of the 19th century; that the ability of the League of Nations to become an effective instrument for the preservation of peace was jeopardized first by the political conflict between Great Britain and France, then between France and Germany, and finally between Great Britain and France on the one hand and the Soviet Union on the other; and that the United Nations as a peacemaker was paralyzed from the very beginning by the conflict between the Western world, under the leadership of the United States, and the Soviet bloc.

The attempts to secure peace by an international government of sovereign nations have all been the victims of a contradiction inherent in these very attempts. The establishment of an effective government of sovereign nations seems to be a contradiction in terms that can be eliminated only by a direct attack upon national sovereignty itself.

The World State.—A proposal that seems to many to offer a logical solution to the problem of international peace is the world state. In the same way, so it is argued, in which domestic peace has been made secure by the subjection of local and regional governments to a common authority, so international peace, to be secure, must be built upon the foundations of a government for all mankind to which national governments must yield their sovereignty.

Any world government, if it is not a tyrannical one, must rest on a triple foundation: supranational loyalties, expectation of justice, and overwhelming power. That is to say, whenever a conflict arises between loyalty to a particular nation and loyalty to the world government, the latter must be reasonably certain that the conflict will be resolved in its favour. Furthermore, the peoples of the world must be united in the reasonable expectation that the world government will at least approximate justice in its dealings with them. Finally, the world government must have at its disposal such overwhelming physical strength as will make unlikely from the outset physical resistance to its decisions on the part of any group subject to its rule.

To realize these three preconditions for a world state capable of preserving peace two methods have been suggested and partly put into practice: one constitutional and one functional. A number of organizations have worked out constitutions for a world state, generally on a federal basis. Once such a constitution has been ratified by the representatives of the nations of the earth, its actual operation is expected to call into being the three foundations upon which an effective world state must rest. On the other hand, there are those who believe that before a world state can be brought into being, humanity must experience its community of interests and develop the foundations for a world state through active cooperation for specific limited objectives. Once humanity has learned to cooperate, say, for the improvement of health or the increase in agricultural production regardless of national boundaries, its political unity will grow almost organically from common needs successfully met and the common interest in their continuing satisfaction. Hence, this functional approach puts its main reliance for preparing humanity for a world state upon the so-called specialized agencies of the United Nations and similar organizations; it points to the European communities, such as the European Coal and Steel Community, Euratom (European Atomic Energy Community), and the Common Market, as precedents.

Diplomacy.—The chief instrumentality through which states have actually attempted to preserve international peace by reconciling hostile interests that threaten to lead to war has continued to be diplomacy. It is the oldest and most natural method for the settlement of international disputes; for sovereign entities, such as nations, which by definition are not subject to a higher authority, must naturally try to settle their disputes peacefully by way of negotiation, that is, through diplomacy. The decisive factor in such diplomatic negotiations is the interest of the negotiating parties in the success of the negotiations. This interest generally takes two different forms. On the one hand, the negotiating parties expect from the peaceful settlement the protection and promotion of their vital interests, while both are willing to compromise on secondary issues, thus each giving up something and receiving something. On the other hand, the interest of the parties in concluding an agreement and, more particularly, in keeping it depends upon the political and military pressures which one side is able to exert upon the other in support of a peaceful settlement. This has been one of the traditional functions of competitive armaments, alliances, and the balance of power. Diplomacy as a method of preserving peace has been deprecated to the extent that the newer methods, mentioned above, have captured the popular imagination. That deprecation is based on moral as well as practical grounds. Yet, though diplomacy is defective on both counts, governments, while experimenting with the newer methods, have continued to put their main reliance upon the traditional methods of diplomacy. It is worthy of note to what extent, for instance, the United Nations, which was widely supposed to provide a substitute for the traditional methods of diplomacy, was transformed into an instrument of diplomacy, used by individual nations for the protection and promotion of their particular interests. However, the search for a more effective method of preserving peace than diplomacy can provide, which has occupied humanity to an ever increasing extent since the beginning of the 19th century, reflects the new and ever increasing urgency which the problem of peace has assumed. For political, technological, and moral revolutions have transformed war from the rational instrument of foreign policy that it once was into an instrument of universal destruction. And it became one of the great paradoxes of the 20th century that as the preservation of peace became a matter of survival for Western civilization the traditional instruments of preserving it had become less effective; and more effective ones had not yet been devised.

PEACE CORPS, an agency of the U.S. government established by Executive Order 10924 issued by Pres. John F. Kennedy on March 1, 1961. It became a permanent agency under the Department of State the following September when Congress approved the Peace Corps Act. Its first annual budget was $30,000,000. The Peace Corps, in the words of President Kennedy, was to be "a pool of trained American men and women sent overseas by the United States Government to help foreign countries meet their urgent needs for skilled manpower."

In the period following World War II, many European colonial possessions became independent nations. At the same time other developing countries began to build their own modern political and economic systems. The progress of many of these nations was impeded because their citizens lacked technological skills. The Peace Corps was formed to help solve this problem by enabling experienced Americans to share their knowledge in education, agriculture, health, trade, technology, and community development with nations trying to build their own pools of trained manpower.

Peace Corps volunteers must be U.S. citizens and must be at least 18 years old; there is no upper age limit. Married couples without dependent children are eligible if both husband and wife can do needed jobs. Each volunteer must answer a Peace Corps questionnaire and take a placement test, a one-hour general aptitude examination. On the basis of the candidate's skills, education, and experience he is assigned to a project that has been requested by one of the many countries in which the Peace Corps serves.

To prepare for this assignment, the volunteer studies for three months at a U.S. college or university. More than 90 colleges have conducted intensive instruction in the language, history, politics, and customs of various countries to which volunteers have been sent. During this training period the volunteer candidate also studies American history and policies and takes some training in the special skill that he brings to the program.

Once overseas, the volunteer functions as a good neighbour by working directly with the people of the host country, speaking their language, and sharing their lives. Each volunteer receives a living allowance comparable to that of his counterparts in the host country. The normal term of service is two years, at the end of which the volunteer receives a termination payment of $1,800 (less taxes). Peace Corps service does not exempt volunteers from military duty.

In 1961, the first year of the Peace Corps, 900 volunteers served in 16 different countries of Latin America, Asia, and Africa. The cost per volunteer for staff support, training, transportation, allowances, and equipment was $8,000. In 1964, because of increased requests from host countries, 10,000 volunteers were at work in 46 different countries and the Corps' budget was $104,100,000.

The Peace Corps maintained a headquarters staff in Washington, D.C., and a small staff in each host country to allocate the work

of the organization and to supervise individual projects. In its first years the Peace Corps was administered by R. Sargent Shriver, who held the title of director and was assisted by several associate directors. The largest division of the staff was that of Program Development and Operations. It was divided into four regional offices: (1) Latin America, (2) North Africa, Near East, and South Asia, (3) Far East, and (4) Africa, and was responsible for developing and administering the Peace Corps programs with the host countries. The other divisions were the Planning, Evaluation, and Research Division, which was concerned with the effectiveness of Peace Corps projects; the Public Affairs Division, which handled recruiting, congressional liaison, and public information; the Peace Corps Volunteers Division, which selected and trained the volunteers and provided support once they had been sent overseas; and the Management Services Division, which was responsible for the personnel section and the finances of the agency.

The overseas staff consisted of a Peace Corps director for each country, assisted by one or more associate directors and a medical doctor. They were responsible for the well-being and work performance of the volunteers; they also served as the channels of communication between Washington and the host country.

The record of the Peace Corps can be evaluated in several ways. Its popular appeal was indicated by the fact that more than 1,000 Americans applied for service each week in 1964. Every country that originally asked for volunteers doubled, tripled, and even quadrupled its first requests. One of the finest tributes to the Peace Corps was the 1963 Ramón Magsaysay Award, the $10,000 prize given to persons in Asia who "exemplify in spirit, integrity and devotion to liberty" the late president of the Philippines. This Asian equivalent to the Nobel Prize had never before been won by a non-Asian group. (S. Sr.)

PEACE PIPE: *see* Calumet; Pipe Smoking.

PEACE RIVER, a part of the great Mackenzie River (*q.v.*) system of western Canada, rises as the Finlay River in the Rocky Mountains of north central British Columbia. The length is 1,195 mi. Breaking through the mountains it flows northeast through Wood Buffalo National Park into the Slave River, near Lake Athabasca, in Alberta. The district between 55° and 60° N. and between 112° W and the Rocky Mountains, is commonly known as the Peace River country. Some parklike openings in the forests and a slightly longer growing season and better soil than the surrounding area attracted farming settlement to the Peace River country before World War I. In the latter half of the 20th century more than 4,000,000 ac. were in farms. The most important crop is barley; oats, wheat, and forage seeds are also grown. There are great deposits of coal, and after 1952 the region became a major producer of natural gas and petroleum. Pipelines connect the gas and oil fields to southern markets. Forest resources are also important. The Peace River country was connected by rail with Edmonton in 1914 and with Vancouver in 1958; the Alaska Highway begins at Dawson Creek, B.C., and crosses the Peace soon after. The Peace is navigable from Peace River, Alta., to the Slave, except for Vermillion Falls near Fort Vermillion, Alta. (Jn. H. W.)

PEACH, CHARLES WILLIAM (1800–1886), British naturalist and geologist who made valuable contributions to the knowledge of marine invertebrates and of fossil plants and fish, was born on Sept. 30, 1800, at Wansford in Northamptonshire. He received an elementary education at Wansford and at Folkingham in Lincolnshire, and for several years assisted his father in the operation of an inn and farm.

In 1824 the earl of Westmorland appointed him riding officer in the revenue coast guard at Weybourne in Norfolk. Seaweeds and other marine organisms attracted his attention, and he began to collect them. His duties during the next few years led him to move to several different places in Norfolk and in the course of his rambles he met the Rev. James Layton, curate at Catfield, who lent him books and assisted in laying the foundations for his future studies. He was finally sent to Gorran Haven in Cornwall where he continued to pursue his studies and supplied many specimens to the British naturalist G. Johnston, who was then preparing his *History of the British Zoophytes* (1838). It was there also that Peach found fossils in some of the older rocks previously regarded as unfossiliferous. This discovery proved the presence of Bala beds (Ordovician) in the neighbourhood.

In 1841 he read a paper before the British Association at Plymouth entitled "On the Fossil Organic Remains Found on the South-east Coast of Cornwall," and in 1843 he brought before the Royal Geological Society of Cornwall an account of his discovery of fish remains in the Devonian slates near Polperro.

Peach was appointed to a position in the customs at Fowey in 1845; and four years later he went to Scotland, first to Peterhead and in 1853 to Wick. He studied the Old Red Sandstone, the boulder clay of Caithness and the Carboniferous plants of Scotland. During a stay at Durness he first found fossils in the Cambrian limestone (1854). In the field of natural history his contributions included the discovery of many new species of sponges, coelenterates, and mollusks. He died at Edinburgh on Feb. 28, 1886.

PEACH (*Prunus persica*), a fruit tree grown throughout the warmer temperate regions of both the Northern and Southern Hemispheres. It belongs to the Prunoideae subfamily of the rose family (Rosaceae), which also includes the cherries, plums, and apricots, a group known as drupes or stone fruits.

History.—It was long thought that the peach originated in Persia as is suggested by the specific name *persica.* It is now reasonably certain that the original home of the peach was China and that it spread westward along the caravan routes through Asia to the Mediterranean countries and later to other parts of Europe. It has long been cultivated in China and reference to *Tao,* meaning "peach," has been found in Chinese writings of the 5th century B.C. The Greeks and Romans are believed to have had the peach shortly after the beginnings of the Christian era; it then was introduced to countries under their influence. The Spanish explorers brought the peach to the New World, and as early as 1600 the fruit was found in Mexico. Explorers, settlers, and Indians were responsible for the wide distribution of the fruit in the Western Hemisphere.

Plant Characteristics.—*Growth Form.*—The tree is small to medium sized, seldom reaching 25 ft. in height. Under cultivation, however, it is usually kept to between 10 and 12 ft. in height by pruning. The leaves are glossy green, lance-shaped, and long-pointed; they usually have glands at their bases, which secrete a fluid that attracts ants and other insects. The flowers

PEACH BLOSSOMS (PRUNUS PERSICA)

FRED BOND—PUBLIX

are borne in the leaf axils and are arranged singly or in groups of two or three at nodes along the shoots of the previous season's growth. The five petals, usually pink but occasionally white, five sepals, and three whorls of stamens are borne on the outer rim of the short tube that forms the base of the flower. The pistil consists of a single carpel with a relatively long style and an enlarged basal portion, the ovary, which becomes the fruit.

The Fruit and Its Composition.—While the skin of most ripe peaches is downy or fuzzy, there are some smooth-skinned peaches called nectarines, which are otherwise indistinguishable from ordinary peaches. The glabrous character of the nectarine is hereditary; peach seeds carrying this factor may give rise to nectarines. A branch bearing nectarines is occasionally produced as a sport or mutation on a peach tree (*see* NECTARINE).

FRED BOND—PUBLIX

RIPE PEACH (PRUNUS PERSICA)

The peach develops from a single ovary that ripens into a fleshy, juicy exterior, making up the edible part of the fruit, and a hard interior called the stone or pit. Of the two ovules in the ovary usually only one becomes fertilized and develops into a seed, which is enclosed within the stone. This frequently results in one half of the fruit being slightly larger than the other, the two halves forming the slight longitudinal cleft typical of drupe fruits. The flesh may be white, yellow, or red. Varieties may be freestone types, which have stones that separate easily from the ripe flesh, or clingstones, which have flesh that adheres firmly to the stone.

The peach is about 87% water. It has fewer calories than either apples or pears; its protein and fat content are negligible. Yellow-fleshed types are especially rich in vitamin A, containing more than four times as much as an orange of the same size.

Cultivation.—For centuries the cultivation and the selection of new varieties was largely confined to the gardens of the nobility, and large-scale commercial peach growing did not begin until the beginning of the 19th century, in the United States. The early plantings were of seedling peaches, inevitably very variable and often of poor quality. The practice of budding superior sorts onto hardy seedling rootstocks, which came later in the century, led to the development of large commercial orchards. The most important limiting factor in peach production is cold injury to the wood and buds during the winter or frost injury at blossoming time. Peaches are intolerant of severe cold, and cannot be grown successfully where winter temperatures normally fall to −23° to −26° C (−10° to −15° F); only the most hardy varieties can withstand these temperatures. On the other hand, peaches do not grow satisfactorily where the winters are too mild. Most varieties require some winter chilling to induce them to burst into growth after the annual dormant period. If there is not sufficient cold to break this dormancy, the trees come into leaf slowly or not at all and the blossoms tend to drop off. In regions with warm winter climates, only those varieties with a low chilling requirement succeed.

The peach does well on various soil types, ranging from the coarse-textured sand or gravelly loams and shales to silt loam, but in general it grows best on well-drained sandy or gravelly loams. Fine-textured soils that have a tendency to waterlog or have poor subsoil drainage are unsatisfactory. In regions where low winter temperatures and spring frosts are hazards, the orchard site should be sufficiently elevated in relation to the surrounding land to permit cool air to drain away to lower levels. Large bodies of water may have a moderating effect in regulating temperatures and reducing frost hazard.

Peach trees should be pruned annually to prevent them from becoming too tall and leggy. Pruning back upright shoots to outgrowing laterals will help to produce a spreading tree and keep it open to sunlight. In general, peaches grow best when the soil around the tree is cultivated. Mulching with organic material will keep down competition of field grasses and conserve moisture. On most soils the peach responds well to nitrogen-rich fertilizers or manures, without which satisfactory growth cannot be obtained.

Most peach varieties produce more fruits than can be maintained and developed to full size. Some shedding of fruitlets takes place naturally, about a month to six weeks after full bloom, but the number remaining may have to be reduced further by hand thinning. This should be done as soon after the natural drop as possible.

Peach trees are relatively short-lived as compared with some other fruit trees. In some regions orchards are replanted after 8 to 10 years, while in others trees may produce satisfactorily for 20 to 25 years or more, depending upon their resistance to diseases, pests, and winter damage.

Varieties.—Thousands of varieties of the peach have been selected and in 1917 more than 2,000 varieties were described as being grown in the United States. Yellow-fleshed varieties are preferred in North America, and practically all the varieties grown commercially are of this type. In Italy, which represents European preference, 60% of the peaches grown are white-fleshed. Most of the varieties now grown commercially round the world are of American origin. The most widely known of all varieties is Elberta, produced in the United States in 1870 and still one of the most widely grown freestone peaches.

In most of the main peach-growing countries peaches are available for the four or five summer months. With the constant introduction of new varieties, lists of recommended sorts soon become out-of-date, but some well-tried varieties continue to be popular. Dixiered, an early producer among the early ripening yellow-fleshed freestones, is followed by Redhaven, Golden Jubilee, Triogem, Halehaven, Elberta, and J. H. Hale. The important firm-fleshed clingstones grown for canning include Halford, Gaume, Paloro, Peak, and Fortuna. Among the white-fleshed varieties favoured in Europe, Mayflower starts the season and is followed by Amsden, Bella di Roma Precoce, Charles Ingouf, Hales Early, and Belle of Georgia.

Pests and Diseases.—Peaches are attacked by many insects, nematodes, and fungus and bacterial diseases. Few fruits of good quality are obtained without the use of pesticides. Fortunately most of the pests and diseases can be controlled by chemical sprays and general orchard cleanliness. Mites, aphides, caterpillars, and scale insects (of which the San Jose scale is the worst) all attack the peach. Brown rot, due to species of the fungus *Sclerotinia*, causes rotting of the fruit on the tree and in storage; less seriously it causes blossom and twig blight and cankers. Peach leaf curl, which probably spread from Europe, is caused by the fungus *Taphrina deformans;* it is the most easily recognized disease, deforming the leaves and causing early defoliation. Peach scab (*Cladosporium carpophilum*) causes unsightly markings on the fruit. Peach blight or fruit spot, caused by *Coryneum beijerinckii,* attacks the blossom, leaves, and fruit and, like the others, is of almost worldwide distribution. Bacterial canker, silver leaf, and mildew are also troublesome. Virus diseases such as peach yellows, rosette, little peach, and peach mosaic are serious ailments that cannot be controlled by spraying. Most of these virus diseases are spread by insects or grafting. The best checks are to eradicate diseased trees, to control insect vectors, and to propagate only from virus-free trees. (*See* also FRUIT FARMING; HORTICULTURE.)

Production.—The peach is the third most important of the deciduous tree fruits, ranking after the apple and pear. The United States, where the peach ranks second to the apple in importance, produces almost half of the world's supply of this fruit; California leads among the states in the production of both freestone and clingstone peaches. In that state a large commercial industry has been developed in the production and canning of firm-fleshed clingstone varieties; freestone varieties are used chiefly for fresh fruit and for drying. In Europe, Italy, with a 1,000,000-ton annual crop, a quarter of the world's supply, is the leading peach producer, followed by France, Spain, and Greece. Elsewhere, Argentina, Japan, Turkey, Canada, South Africa, and Australia produce substantial crops.

PEACHAM, HENRY (*c.* 1576–*c.*1643), English author best known for his *Compleat Gentleman* (1622), important in the tradition of courtesy books, was born at North Mimms, Hertfordshire, about 1576. He was educated at Trinity College, Cambridge, and was successively schoolmaster, traveling tutor, and author. Of his time as master of the free school at Wymondham, Norfolk, he wrote "whiles that it was free, Myselfe, the Maister, lost my libertie." His first book, *The Art of Drawing With the Pen, and Limning in Water Colours* (1606), dealt with a lifelong interest; his translation (1610) into Latin verse of King James's *Basilicon Doron* contained his own pen-and-ink drawings. *The Period of Mourning* (1613) honoured the memory of Prince Henry, and *Thalia's Banquet* (1620) proved Peacham's ability to turn an epigram. *The Truth of Our Times* (1638; ed. by R. Cawley, 1942) is full of acute observations on the London life he knew so well; he recalled seeing the acting of the great Richard Tarlton "when I was a Schoolboy in *London*." *The Worth of a Peny* (1647; in E. Arber's *English Garner*, vi, 1883) is Peacham's "complaint to his purse." But his chief work remained *The Compleat Gentleman* (ed. by G. S. Gordon, 1906). It was a full expression of his theories on education, and its table of contents exhibits the variety of his interests: cosmography, geometry, poetry, music, sculpture, drawing, painting, heraldry. Dr. Johnson drew the heraldic definitions for his *Dictionary* from the 1661 edition.

Peacham was royalist to a fault, writing in 1639 *The Duty of All True Subjects to Their King as Also to Their Native Countrey;* and he spoke proudly of having sketched the king's portrait as he sat at dinner. Though he attacked Puritans in *Thalia's Banquet*, he had some natural sympathy with them, deploring lavishness of every kind. He concludes *The Truth* with a quotation from Hippocrates: "All things moderately, and in measure."

See M. C. Pitman, "Studies in the Works of Henry Peacham," *Bulletin of Historical Research*, xi (1934). (R. R. Cy.)

PEACOCK, THOMAS LOVE (1785–1866), English poet and satirical novelist, in whose novels conversation is more important than character or plot, was born at Weymouth on Oct. 18, 1785. His father was a glass merchant, his mother a Devon woman with marked literary interests. Peacock was deeply attached to his mother, who lived to be nearly 80, and used to read his writings aloud for her criticisms. At ten he was already writing verse. He was not sent to a public school or university, but spent six and a half years at a private school and then seems to have gone straight into a business firm as a clerk. He was a self-educated man whose knowledge of the Greek and Latin classics was the result of his own study and enthusiasm. In 1804 he published *The Monks of St. Mark*, followed by other poems (*Palmyra, The Genius of the Thames*, and *The Philosophy of Melancholy*) between 1806 and 1812. In 1818 *Rhododaphne* appeared. Peacock is mainly remembered as a poet for the lyrics in his prose writings, but some of his other poems also contain fine passages. About 1810–11 he wrote *The Dilettanti* and *The Three Doctors*, farces which anticipate his later satires. In 1812 he met Shelley, whose close friend he soon became. The months that he spent near the Shelleys at Great Marlow in 1817 seem indeed to have been the main seminal period of his life, and the ideas that lie behind many of the witty dialogues in his books probably found their origin in the conversation of Shelley and his friends. A brief essay which he published in the first number of *Ollier's Literary Miscellany* (1820), "The Four Ages of Poetry," provoked Shelley to write his luminous *Defence of Poetry*. In the same year Peacock married Jane Gryffydh, a parson's daughter.

In his essay on "French Comic Romances" (*The London Review*, October 1835), Peacock distinguishes between comic romances in which "the characters are abstractions . . . and their opinions [are] the main matter of the work" and those in which "the characters are individuals, and the events and the actions those of actual life." Whereas most English novels fall into the latter category, Peacock's satiric tales belong to the former and should strictly not be described as novels at all. *Headlong Hall* (1816) was a foretaste of what was to come: the discussion of progress which begins in ch. i does not come to an end until the conclusion of his last novel, *Gryll Grange* (1860), while one need go no further than the second chapter to find the characters seated at table and embarked on the learned and philosophical discussion of food and drink which forms the leitmotiv of all his books. As in the most characteristic of the later books, there is little in the way of plot: a tenuous love story serves to hold the book together, but the main ingredients are satirical description, narrative, and above all dialogue in which many of the common opinions of the day are presented and criticized. The characters are "humours," no attempt being made to present them in the round. In *Melincourt* (1817), which is much longer and in which the action is set in the Lake District, there is the same basic structure. The idealistic lovers, Anthelia and Sylvan Forester (partly a representation of Shelley), stand in sharp contrast to most of the other characters, and the book as a whole is a passionate protest against the corruption, anti-jacobinism, and obscurantism that ran riot in the period of repression that followed Waterloo. As a satire on parliamentary corruption, an ape (Sir Oran Haut-ton) is elected M.P., while a definition of "the spirit of chivalry" is described by a friend of Southey as containing "all the ingredients of a rank Jacobin." Peacock's anticlericalism is particularly evident in this book: in ch. 39 Wordsworth and John Wilson Croker join Southey and George Canning in chanting "The church is in danger! The church is in danger!"

In *Nightmare Abbey* (1818) the reader is again presented with a house party and a number of "humours," but for once there is a plot with unforeseen incidents and a reversal of fortune. Scythrop is a representation of the young Shelley, with his passion for reforming the world: the outcome of his pursuit of two young women is that each of them marries another man. The atmosphere of the book is one of ironically described gloom: it is in fact a satire on romantic melancholy. Mr. Flosky is a satire on Coleridge and Mr. Cypress a satire on Byron. (His song "There is a fever of the spirit" is an admirable parody.) In *Maid Marian* (1822) and *The Misfortunes of Elphin* (1829) Peacock attempted to graft satire onto the historical romance, but in spite of some admirable passages neither is a successful whole. His greatest achievements are *Crotchet Castle* (1831) and *Gryll Grange* (1860), in which he returned to the pattern of *Headlong Hall*. Once again there is a host who loves conversation, a clerical gourmand, a pair of romantic young lovers, and a train of "humours." Dialogue is more prominent than ever. Like *Melincourt*, *Crotchet Castle* belongs to a particular period: the time when agitation about parliamentary reform was at its height. The main theme of the book is introduced when the Rev. Dr. Folliott bursts into the breakfast room and announces that he is "out of all patience with this march of mind." The troubles of the time lie rather heavily over this book, however, and it lacks the serenity that is one of the charms of *Gryll Grange*. Peacock's last book contains the same ingredients as its predecessors, but this time the mixture has "risen" to perfection. It dates hardly at all, partly because Peacock had ceased to worry about contemporary problems.

Almost the whole of Peacock's working life was spent in the service of the East India Company. He was an able administrator, and in 1836 he succeeded James Mill as chief examiner. In 1856 he retired on a pension. During the last years of his life he wrote his admirable *Memoirs of Percy Bysshe Shelley* as three articles in *Fraser's Magazine* (1858–62). He died at Lower Halliford on Jan. 23, 1866.

(1924–34), vol. i of which contains the fullest biography. There is a useful one-vol. edition of the *Novels*, ed. by David Garnett (1948). *See* also J. B. Priestley, *T. L. Peacock* (1927); J.-J. Mayoux, *Un Épicurien anglais: T. L. Peacock* (1933). (I. J.)

PEACOCK, the male of the largest and most splendid of the pheasants, *Pavo cristatus*, a native of India and Ceylon. The female is the peahen; collectively, both are peafowl. The male has a crest and whitish bare areas on the sides of the head; the plumage is brilliant metallic green and blue. The upper tail coverts are

CLARENCE D. COOK FROM NATIONAL AUDUBON SOCIETY

PEACOCK (PAVO CRISTATUS) DISPLAYING

enormously elongated, forming the train of about six feet in length, bronzy-green and blue in colour and ornamented with brilliantly coloured eye spots, or ocelli. A white variety is common in captivity. In courtship display, the train is erected vertically above the bird's back, being supported by the tail feathers. At the climax of the display the tail feathers are vibrated, giving the feathers of the train a shimmering appearance and imparting a rustling sound.

Wild peafowl live in small flocks in open forest but roost in tall trees, which they begin to ascend, in gradual stages, in the afternoon. In captivity the bird often displays outside courtship periods, seemingly showing off, hence the saying, "proud as a peacock." The female is much more dully coloured and lacks the ornamental feathers. The peacock is polygamous, each male seeking to acquire a harem of four or five hens. During the breeding season the male utters a raucous, harsh cry. The hen lays from four to six whitish, sometimes spotted eggs in a hidden nest.

This beautiful bird, seen in almost every zoo and in some large estate gardens, has long been famous, especially since it adapts readily to domestication. The Phoenicians introduced it to the Pharaohs of Egypt, and Alexander the Great took it to Greece. The feathers were exported from India in quantities for ornamental use, although a superstition against the eye spots on the feathers as being evil somewhat lessened their popularity. In Rome and later in medieval Europe, peafowl were raised for the table. The emperor Charlemagne is said to have served thousands at a single state banquet. After the turkey was brought to Europe from Mexico, it quickly supplanted the peacock as a table bird.

A related species, the green peacock (*P. muticus*), inhabits Burma, Indochina, Malaya and Java. The name is also applied to other less closely related pheasants such as the Congo peacock (*Afropavo congensis*) and the peacock pheasant (*Polyplectron*). *See* PHEASANT.

(DN. A.; X.)

PEAK DISTRICT, a heavily dissected plateau in north Derbyshire, Eng., forming the southern extremity of the Pennines. It includes an area of about 500 sq.mi. (1,295 sq.km.), mainly peaty moorland drained by tributaries of the Mersey and the Derwent. Kinder Scout, 2,088 ft. (6,346 m.), is the highest point, with summit areas of Millstone Grit. Many of the rivers, notably the Wye and the Dove, have cut through this to the underlying massive limestones and their gorgelike valleys are very picturesque. Caverns and potholes occur frequently. (*See* DERBYSHIRE.) In 1950–51 the Peak District National Park was formed, and in 1954 a warden service for patrolling the access land was inaugurated. The district is a popular walking and camping area.

PEALE, the name of a family of notable U.S. painters during the late 18th and early 19th centuries.

CHARLES WILLSON PEALE (1741–1827), whose portraits of the leading figures of the Revolutionary period are the most remembered of his remarkably diverse accomplishments, was born in Queen Annes county, Md., on April 15, 1741. His career in art began in 1763. John Hesselius, a successful Maryland painter, gave him lessons and John Singleton Copley advised and influenced him. From 1767 to 1769 he studied in London with Benjamin West, absorbing West's neoclassical style and the new ideals of social and political justice associated with neoclassicism. In an allegorical portrait of Pitt he sounded a warning to tyrants, and he refused to uncover when the coach of King George III passed in the streets.

On his return to America, Peale became at once the fashionable portrait painter of the middle colonies. He moved to Philadelphia in 1776, entered wholeheartedly into the Revolutionary movement and served with the city militia in the Trenton-Princeton campaign. From 1779 to 1780 he represented the "Furious Whig" party in the Pennsylvania assembly, an activity which damaged his professional career. In 1781 he opened a portrait gallery of Revolutionary heroes. In 1784 he founded the institution which became famous as Peale's museum, a pioncering venture in museum exposition and a new expression of his liberal philosophy, which was intended to illustrate nature and natural law. The first scientific expedition organized in the United States brought to it in 1801 the first complete skeleton of the American mastodon. The museum grew to vast proportions and was widely imitated by other museums of the period and later by P. T. Barnum.

In his long life, Peale painted about 1,100 portraits, including virtually all his great contemporaries. His seven life portraits of Washington of 1772, 1776, 1777, 1779, 1783, 1787 and 1795 were repeated many times by himself and other painters of his family. He died in Philadelphia, Feb. 22, 1827.

His brother, JAMES PEALE (1749–1831), became well known as a miniaturist and a painter of portraits, landscape and still life. He served as an officer of the Continental army, and painted a small group of Revolutionary battle scenes.

REMBRANDT PEALE (1778–1860), a son of Charles Willson Peale, was born in Bucks county, Pa., on Feb. 22, 1778. He studied first with his father, then at the Royal Academy in London in 1803 and between 1808 and 1810 in Paris, where he was offered the post of portrait painter to Napoleon's court. In 1814 he founded the Peale museum in Baltimore. Ambitious to rise above portrait work, he painted a number of formal subject pieces culminating in his huge "Court of Death" of 1819 (Detroit Institute of Arts), a picture whose exhibition brought the artist $19,000 in the first year.

In 1823, invoking both study and inspiration, he painted a head of George Washington, whom he had painted from life in 1795. This strong but idealized likeness enjoyed great popularity and was

PORTRAIT OF JAMES PEALE (THE "LAMPLIGHT PORTRAIT"). BY CHARLES WILLSON PEALE. IN THE DETROIT INSTITUTE OF ARTS, DETROIT, MICH.

BY COURTESY OF THE DETROIT INSTITUTE OF ARTS

repeated by him many times. He sold his museum in 1822 and thereafter devoted all his time to art, painting in New York, Boston, Philadelphia and other cities. His portraits include many distinguished figures, that of Thomas Jefferson being perhaps his masterpiece, as well as the best portrait of the president. His writings include *Notes on Italy* (1831), *Graphics* (1835), *Portfolio of an Artist* (1839) and reminiscences appearing in C. E. Lester's *Artists of America* (1846) and the *Crayon* (1855–57). He died in Philadelphia, Oct. 3, 1860.

Rembrandt's brother, RAPHAELLE PEALE (1774–1825), was a master of *trompe-l'oeil* and founder of the art of still-life painting in the United States.

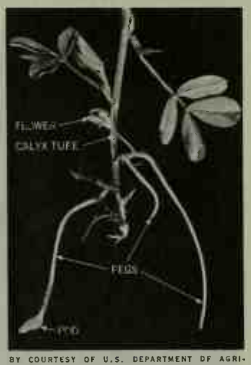
See Charles C. Sellers, *Charles Willson Peale,* 2 vol. (1947) and *Portraits and Miniatures* (1952). (C. C. Ss.)

PEANO, GIUSEPPE (1858–1932), Italian mathematician and logician, whose interests were concentrated on the foundations of mathematics and on the development of a formal logical language. Born at Cuneo, Aug. 27, 1858, he became professor of infinitesimal calculus at the University of Turin in 1890 and also at the Accademia Militare from 1887 to 1901. His *Formulaire de mathématique* (*Formulario Mathematico*), published from 1894 to 1908 with collaborators, sets forth the fundamental postulates of mathematics in Peano's notation, part of which was adopted by Bertrand Russell and Alfred N. Whitehead in their *Principia Mathematica* (*see* LOGIC, HISTORY OF). His name is particularly associated with the axioms for the integers (*see* NUMBER: *Ordinal or Inductive Definition*), and with the discovery of the Peano spaces (*see* TOPOLOGY, GENERAL).

He is known as the creator of an international language (*q.v.*), the *latino sine flexione,* based upon words most common in Western European languages. He compiled a *Vocabulario de interlingua* (1915) and was president of the Academia pro Interlingua. He died at Turin, April 20, 1932. (O. OE.)

PEANUT (GROUNDNUT, EARTHNUT, GOOBER), despite its several common names, is not a true nut but the pod, or legume, of *Arachis hypogaea* (family Leguminosae), which has the peculiar habit of ripening underground. It is a concentrated food: pound for pound peanuts have more protein, minerals, and vitamins than beef liver; more fat than heavy cream; and more food energy (calories) than sugar. Native to tropical South America, the peanut was at an early time introduced into the Old World tropics. India, China, West Africa, and the United States have become the largest commercial producers of peanuts. There are three major peanut-producing regions in the U.S.: Virginia-Carolina grows mainly the large Virginia type; Georgia-Florida-Alabama grows the Southeastern Runner, Virginia, and Spanish types; and Oklahoma-Texas grows mainly the Spanish type.

The plant is an annual ranging from an erect or bunch form 1½–2 ft. high, with short branches, to a spreading or runner form 1–1½ ft. high with branches up to 2 ft. long that lie close to the soil. The stems and branches are sturdy and hairy; leaves are pinnately compound with two pairs of leaflets. The flowers are borne in the axils of the leaves; what appears to be a flower stalk is a slender calyx tube up to 1½ in. long; the golden yellow petals are about ⅜ in. across. The pods are most commonly 1–2 in. long, two or three seeded, oblong, roughly cylindrical with rounded ends, contracted between the seeds, and have a thin, netted, spongy shell. The seeds vary from oblong to nearly round; seed coat colours range from whitish to dark purple, but mahogany red, rose, and salmon predominate.



BY COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

PEANUT PLANT SHOWING PEGS THAT PRODUCE PODS UNDERGROUND

After pollination and the withering of the flower, an unusual stalklike structure called a peg is thrust from the base of the flower toward the soil. In the pointed tip of this slender, sturdy peg the fertilized ovules are carried downward until the tip is well below the soil surface. Only then does the tip start to develop into the characteristic pod. The pegs sometimes reach down several inches before their tips can develop fruits. The fruits appear to function as roots to some degree, absorbing mineral nutrients directly from the soil. The pods may not develop properly unless the soil in which they lie is well supplied with available calcium, regardless of the nutrients available to the roots.

The peanut is grown mainly for its edible oil except in the United States, where it is produced for grinding into peanut butter (half the harvested crop); for roasted, salted nuts; and for use in candy and bakery products. A small percentage of the crop is crushed for oil. In the southern United States the peanut is used extensively as feed for livestock. The tops of the plants, after the pods are removed, usually are fed as hay, although the entire plant is sometimes so used.

Profitable growing of peanuts requires at least five months of warm weather with a growing-season rainfall (or irrigation equivalent) of 22–24 in. or more. In Asia the peanut is grown under irrigation. The best soils are well-drained sandy loams 1–1½ ft. deep, underlain by deep, friable loam subsoils. In the United States the shelled seeds are planted in rows 30–36 in. apart. Seeds of the small Spanish type are placed three–four inches apart; the larger varieties are seeded six–eight inches apart in the rows. The seeds are treated with a fungicide to control diseases during germination and seedling emergence. Dusting the plantlets with fungicides to control leaf diseases is usually necessary in humid areas. Careful weed control is essential.

Mechanical injury to the plants by weeding tools or by soil heaped upon them greatly increases the probability of infection and damage by certain soil-inhabiting fungi. Clean cultivation and the use of suitable chemical weed killers help minimize loss from diseases caused by these fungi.

The peanut is susceptible to leaf spot diseases of fungus origin and to insects that defoliate the plants, thereby reducing the yields and the quality of nuts. These blights are readily controlled by timely dusting or spraying with appropriate chemicals. Attacks by certain injurious insects and nematodes in the soil are less successfully controlled.

At harvest, the entire plant, except the deeper roots, is removed from the soil. The nuts are best cured by allowing the harvested plants to wilt for a day, then placing them for four to six weeks in stacks three–four feet in diameter and six feet high, each stack built around a sturdy stake driven upright into the soil. The pods are placed toward the inside of each stack to protect them from weather. Too rapid drying of the nuts impairs seed viability and eating quality. To an increasing extent in the United States, labour shortages necessitate curing the plants in windrows in the field, from which the pods are picked by mobile machines. For picking the pods from stacked plants the stacks are hauled short distances to stationary picking machines. The cured and picked pods are finally cleaned and graded at central establishments.

PEAR, any of several species of *Pyrus,* especially *P. communis,* one of the most important fruit trees of the world, and one cultivated to some extent in all temperate-zone countries of both the Northern and Southern hemispheres. In these regions it is exceeded in importance only by the apple, to which it is related botanically; it surpasses in total production peaches, plums, and cherries. All of these fruits belong to the rose family (Rosaceae; *q.v.*). With the aid of hormones, hybrids between apples and pears have been produced but few have survived the first season's growth; likewise when grafted or budded one on the other, the union is usually short lived.

There are about 20 species of *Pyrus,* all originating in the area from Europe eastward through Asia to China and including North Africa. No species of pear is native in the New World or the Southern Hemisphere. The common pear (*P. communis*), a na-

FRED BOND—PUBLIX

PEAR BLOSSOMS (PYRUS COMMUNIS)

tive of southeastern Europe and western Asia, is the species from which most of the high-quality varieties with juicy, melting flesh have been derived. Many of the varieties widely grown in Europe for the making of perry (*q.v.*), an alcoholic beverage prepared from fermented pears, are derived from the snow pear (*P. nivalis*). The Chinese sand pear (*P. pyrifolia*) is the parent of most Asiatic varieties, characterized by coarse-textured flesh and prominent stone cells. This species is included in the ancestry of some of the varieties most widely grown in the eastern United States. Sand pears and other Oriental species are generally more resistant to fire blight disease (*see* below) than varieties developed from *P. communis*. Oriental species like *P. ussuriensis*, *P. betulaefolia*, and *P. calleryana* have been used to breed varieties resistant to fire blight and to provide blight-resistant rootstocks.

History.—The common pear has been cultivated since long before the Christian era. Homer, nearly 10 centuries B.C., listed pears as one of the fruits in the garden of Alcinous, indicating that they were known to the Greeks of his day. Improved varieties propagated by grafting were known prior to the time of Christ. Thousands of varieties have been bred and named since that time in Europe alone. The pear was introduced into the New World by British and other north Europeans as soon as the Colonies were established. Also at an early date, the Mission Fathers from Spain took them to Mexico and California.

Plant Characteristics.—*Growth Form.*—The pear tree is broad-headed and up to 45 ft. high at maturity; it is taller and more upright than the apple tree. The roundish to oval, leathery leaves, somewhat wedge shaped at their bases, appear about the same time as the inch-wide, usually white flowers. The pear flower, similar to that of the apple, differs from the latter in having the bases of the five styles separated.

The Fruit and Its Composition.—Pears are generally sweeter and of softer texture than apples. The fruit is distinguished from the apple by the presence of hard cells in the flesh, the so-called grit or stone cells, which are absent in apples. In general, pear fruits are elongate, being narrow at the stem end and broader at the opposite end; some types, particularly among the Oriental pears, are apple shaped. Pears have slightly more protein (though it is an insignificant amount), more minerals, and more sugar than apples. They are, however, less rich in vitamins, containing about ⅛ the vitamin A of apples. Water content and caloric value are similar for pears and apples.

Varieties.—In most pear-growing countries of the world outside Asia, by far the most widely grown pear variety is Williams Bon Chrétien, often known simply as Williams. It was named after the nurseryman who introduced it on the market; on its introduction to America it was renamed after its importer, Bartlett. It is estimated that in the main pear-producing area of the western United States 75% and in Italy 25% of all the pears grown are of this variety. In the United States and Canada varieties such as Beurre Bosc, Beurre d'Anjou, and Winter Nelis are grown. The most popular variety in England and the Netherlands is Conference and in Italy, after Williams, are Curato, Coscia, and Passe Crassane, the last named being also popular in France. The pear acclaimed as having the finest flavour and texture is Doyenne du Comice, produced in France in 1849. In Asiatic countries, local varieties of native species are grown; they are considered low in quality by most Europeans and Americans.

Propagation and Cultivation.—The pear is propagated by budding or grafting a known scion variety onto a rootstock. Many are grafted on seedling pears, usually of *Pyrus communis* origin. In Europe the main rootstock used is vegetatively propagated quince, which produces a dwarfer tree that fruits at an earlier age than most of the trees on pear rootstocks. Some pear varieties—Williams is an example—are not satisfactory when grafted directly on quince and do not form good unions. In such cases a compatible variety is first grafted onto the quince rootstock and the incompatible variety is then grafted onto the compatible variety, a procedure known as double-working.

The pear on its own rootstock thrives best in well-drained, moderate-textured soils that permit deep rooting. It can be grown, however, on heavier and more poorly drained soils than can most other tree fruits. Pears grafted to quince rootstocks, which are more shallow rooted, do better in looser soil; they will not tolerate drought conditions as well as pears on pear rootstocks.

Pear trees are relatively long-lived (50 to 75 years) and may reach considerable size unless they are carefully trained and pruned. Within 4 to 7 years of setting out, the tree should begin to bear satisfactorily; at age 20 to 25 it should yield 25 to 45 bushels of fruit. The usual spacing for standard trees is 20 x 20 ft.; older orchards are more dense, with shorter trees spaced as close as 16 x 16 ft.; dwarf pears can be as close as 12 x 12 ft.

Pears are somewhat less resistant to winter cold than are apples. Most varieties do not survive where minimum temperatures are likely to reach −20° to −30° F (−29° to −35° C). Pears bloom earlier in spring than apples, hence are more subject to damage from spring frosts. Highest quality fruits are produced where summer temperatures are moderately high, and diseases are less serious where the summers are dry. Like other deciduous fruits, pears require a period of winter cold, and are not productive within 25° north or south of the equator, even at elevations where the year-round climate is cool.

Harvesting and Marketing.—Pears must be harvested at the correct stage of development otherwise they do not ripen or store in good condition. The fruits are cooled as quickly as possible after harvesting. The length of time the fruits can be stored depends on the variety and the type of storage. Fruits kept at 34° F (1° C) or slightly lower do not ripen, but proceed to do so when transferred to a temperature of 60° F (16° C). At tem-

RIPE PEAR (PYRUS COMMUNIS)

FRED BOND—PUBLIX

peratures of 32° (0° C) to 34° F (1° C) Williams, or Bartlett can be held in store for six or seven weeks whereas Conference and Beurre Bosc can be kept for three months, then ripened at 60°–65° F (16°–18° C). Pears stored in refrigerated gas (carbon dioxide-oxygen mixture) give better quality fruit, with less wastage and a longer period of ripeness after removal from storage. Late-keeping varieties may be stored under natural conditions of air and temperature quite satisfactorily. Most pears are packed individually wrapped, in single layer trays or in half-bushel or bushel boxes.

Pests and Diseases.—*Pests.*—The codling moth, or apple worm, is a serious pest on pears wherever they are grown. Other insect pests that can be troublesome include the pear midge, the pear leaf blister mite, pear psylla or sucker, pear thrips, several species of scale, and a wide range of leaf-eating insects. Several species of red spider (mites) also do much injury to pear leaves. Where high quality, clean fruit is desired it is necessary to spray the orchard three to six times a year.

Fungus Diseases.—The pear is also subject to a number of fungus diseases controllable by spraying. Pear scab, caused by the fungus *Venturia pirina,* occurs in most areas where the pear is grown, but is of much greater importance in Europe than in North America. Pear leaf spot (*Mycosphaerella sentina*) and pear leaf blight (*Fabraea maculata*) are also fairly widespread in most pear-growing countries. These diseases attack the leaves, causing defoliation. Scab and leaf blight also attack the fruit, causing roughened, scabby spots on the fruit surface and deforming the fruit if it is infected early in its development.

Other fungus diseases that can cause serious trouble are brown rot (*Sclerotinia fructigena*), which attacks pear fruits on the trees, in storage, in transit, or in the market. Canker, caused by *Nectria galligena* or *N. ditissima,* is a problem particularly of trees on heavy soils. The cankers form on branches or on the trunk; if they girdle the stem they can kill the tree.

Fire Blight.—The most serious disease of pears in North America is fire blight, caused by a bacterium (*Erwinia amylovora*). The bacteria invade the bark and succulent tissues. When infection occurs in the main body of the tree, large branches or the whole tree may be killed. The roots are also subject to infection. In climates having warm, humid, rainy summers, the disease has not been successfully controlled on susceptible varieties. General orchard cleanliness and the use of the antibiotic streptomycin and copper-containing sprays applied during and following bloom are helpful in reducing infection. Fire blight has been reported from Japan, Italy, and some other European countries, but outside North America it is only in New Zealand that this disease has come to be of economic importance.

Virus Disease.—A virus disease called stony pit has been reported from many pear-growing countries. This disease, as its name suggests, produces hard, stony pits in the fruit. It appears to be transmitted only by grafting. Control is by propagating only from virus-free trees and rootstocks. Not all varieties are affected, and some appear to be able to carry the disease without showing the characteristic symptoms.

Production and Uses.—As stated earlier the pear is, commercially, the second most important of the world's deciduous fruit trees, exceeded only by the apple. In the United States and Italy, two of the greatest fruit-producing countries, however, the pear ranks third after the apple and peach. In Europe table varieties of pears achieve one-third of apple production and in the United States about one-quarter.

World production of table or dessert pears, excluding those used for perry, is about 5,000,000 tons annually, about half of which is produced in Europe. Italy is the world's leading pear producer. The United States is the second largest producer, the three Pacific Coast states of California, Oregon, and Washington accounting for about 90% of the crop. Other countries having important pear production are China, Japan, Turkey, Argentina, Australia, and South Africa.

In the United States, Canada, and Australia the quantity of fresh fruit used by canners amounts to about half of the total commercial crop; in South Africa canning accounts for 30%. In Europe canning is of relatively minor importance. In France about one-third of the total production of pears is used for making perry; in Germany, half; in Austria, three-quarters; and in Switzerland, as much as four-fifths. *See* also FRUIT FARMING.

PEARL, RAYMOND (1879–1940), U.S. biologist and pioneer expositor of the statistical approach to biology and medicine (biometry). He was born at Farmington, N.H., on June 3, 1879, and studied at the University of Michigan, Ann Arbor, and in Leipzig, Naples, and London. In London, studying with Karl Pearson (*q.v.*), Pearl began his contributions to biometry with investigations on morphologic variations and correlations in man and animals. These studies were continued at the Maine Agricultural Experiment Station, where he was biologist and head of the department of biology from 1907 to 1918. In this period he conducted fundamental studies on the physiology of reproduction in domestic fowl. From 1917 to 1919, he was chief of the statistical division of the U.S. Food Administration.

In 1918 Pearl was invited to organize the department of medical statistics and biometry at the new School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md. In 1925 he was appointed director of the school's Institute of Biological Research. His investigations centred on fertility and population growth, human longevity and the relationship of physique to health and disease. He founded two journals: *Quarterly Review of Biology* in 1926 and *Human Biology* in 1929. Pearl's record of publication was prodigious; his bibliography lists about 700 articles and books. Of the books, the most important and lasting are: *Introduction to Medical Biometry and Statistics* (1923), considered a model for such textbooks; *Studies in Human Biology* (1924), a summary of Pearl's investigations on public health problems and a guide for biostatistical research; *Alcohol and Longevity* (1926), a critical review of the reported findings regarding alcohol on the biological system and a clear description of its noxious and beneficial effects; *The Natural History of Population* (1939), in which he discussed the population problem and laid solid biological foundations for later population studies.

Pearl died at Hershey, Pa., Nov. 17, 1940. (A. Co.)

See Thomas Park's biography of Raymond Pearl in the *Dictionary of American Biography,* vol. XXII, suppl. 2 (1958).

PEARL. A pearl is a concretion formed by a mollusk; it consists of the same material (nacre, or mother-of-pearl) as the mollusk's shell. Every mollusk endowed with a shell can produce pearls. Pearllike chitinous formations also have been found in insects and horny ones occur in horn-bearing mammals. Thus a

NACRE, OR MOTHER-OF-PEARL, IN THE SHELL OF THE GREEN TURBAN (TURBO MARMORATUS)

RUTHERFORD PLATT

pearl might be defined broadly as a concretion of organic origin.

In common usage, however, pearls are understood to be the concretions of mollusks. The characteristics that make such pearls desirable and often highly prized as jewelry are their iridescence and translucence. The more perfect the shape (symmetrical ball- or droplike) and the deeper the pearly lustre, the greater the pearl is esteemed. Only those pearls found in mollusks whose shells are lined with nacre are really fine pearls. Pearls from other mollusks are either reddish or whitish, porcelaneous or lacking in pearly lustre.

An unblemished pearl is one of the most ancient symbols of perfection. Pearls were so highly esteemed in classical Rome that only persons of a specified rank were permitted to wear them. Pliny speaks of pearls as "the richest merchandise of all, and the most sovereign commodity in the whole world." The trade in pearls was conducted by a special corporation whose members were known as *margaritarii*.

In spite of the modern development of the cultured-pearl industry, the demand for naturally occurring pearls of high quality has continued, and fine specimens still command prices amounting to thousands of dollars. However, the peak prices that prevailed in 1928 and 1929 had not been reached again by the early 1960s.

The chief component of the nacre that constitutes the pearl is aragonite, a calcium carbonate distinguished by its orthorhombic crystalline system, its hardness and its lustre. Occasionally a pearl may contain calcite, also a calcium carbonate but differing from aragonite in crystalline structure and other physical characteristics. Nacre contains a small amount of conchiolin, the albuminoid that is the main constituent of the mollusk's outer shell.

The mollusk's shell-secreting cells are located in the mantle, or epithelium, of its body; when a foreign particle penetrates the mantle, shell-building cells attach to the particle and build up layers of pearl around the invading material. If the foreign substance penetrates deeply enough into the mantle or other soft body part, a sac or cyst of tissue is first formed around it; the pearl building takes place within this sac. The cyst process begins as an indentation in the mantle or body tissue and proceeds in a pouch formation with an ultimate closure at the neck. When the sac is located in the mollusk's body so as not to be subjected to any deforming pressure, it tends to be globular or pear-shaped and the pearl that develops inside it consequently assumes either a spherical or a pearlike form. The nacreous layers that comprise a round pearl of good quality are generally built up concentrically.

Pearl formation does not always occur in soft tissue areas where the expanding pearl sac encounters no appreciable resistance. Pearl cysts lodged in muscular tissue, for example, are unable to overcome the resistance of tough muscle fibres and assume irregular shapes. The pearls produced are consequently oddly formed and are termed baroque pearls. If the depth of penetration of the foreign body is not great and the particle lodges between the shell and the mantle, the shell-secreting cells deposit a sacless pearl formation that is attached to the shell. A pearl-bearing sac situated close to the outer surface of the mantle may come in contact with the shell and also become attached to it. Shell-attached pearls that grow into half spheres flat on one side are called blister pearls.

Although the term pearl is somewhat loosely applied to the calcareous concretions found in various types of mollusks, the appellation true pearl is used only to describe the cyst pearl composed predominantly of nacre and formed free within the mollusk's body without attachment to its shell. The true pearl is characterized by its lustre and by a delicate play of surface colour called its orient.

True pearl-bearing mollusks, of which there are both salt-water and fresh-water varieties, are popularly called pearl oysters, which is something of a misnomer, since these mollusks are not of the Ostreidae family of bivalves that includes the *Ostrea edulis*, or edible oyster. Concretions found in the common edible oyster are generally black or purple in colour, sometimes with an admixture of white, and almost never exhibit lustre. They are not true pearls.

The salt-water mollusks most important in natural pearl production belong to the genus *Meleagrina* (or *Pinctada*), formerly and perhaps better known as *Margaritifera*, which belong to the family Aviculidae or Pteriidae. The *Meleagrina* alone yields the most highly prized of all true pearls, the oriental pearl.

ORIENTAL PEARL OYSTER (MELEAGRINA) WITH ATTACHED BLISTER PEARL

True pearls are formed of nacre secreted by mollusks in layers around a particle of foreign matter that has become lodged in the fleshy mantle

Sources of Natural Pearls. —Ranking first among oriental pearls for superior form, lustre and orient are those produced by the *Mohar*, a variety of the *Meleagrina vulgaris* species of mollusk found in the Persian gulf. The richest pearl harvest of the gulf is taken from the waters of the great bight that curves from the peninsula of Oman to that of Qatar, where the pearl banks lie at depths of 8 to 20 fathoms (48 to 120 ft.). Pearls of fine quality are also fished from the pearl banks of the Island of Bahrain.

The Persian gulf pearling fleet is, for the most part, based on the Trucial coast, and fishing is carried on from May through the early part of September. The pearl divers work in pairs, one man remaining at the surface to attend the two lines used; one line, to which is attached a stone weighing about 40 lb., carries the diver downward with baskets to contain the mollusks he gathers, while the second line serves as a signal cord. A diver remains below for 60 to 80 seconds before signaling to be drawn to the surface with his catch. The great pearl market of the Persian gulf has long been the Iranian port city of Lingeh, whose name has become synonymous with the finest of Persian gulf pearls. (*See* also PERSIAN GULF.)

Another important source of oriental pearls produced by the *Meleagrina vulgaris* is the Bay of Bengal in the neighbourhood of Ceylon, particularly in the Gulf of Mannar. These pearls are marketed in the Indian city of Madras, which confers its name on the pearls marketed there. Also marketed in Madras are numbers of African pearls that are taken chiefly from the pearl banks that lie in the coastal waters of east Africa from the Island of Zanzibar to Inhambane in Mozambique. Since the days of the Ptolemies, pearls have also been fished in the Red sea, though the industry there has dwindled to insignificant proportions.

In southeast Asia, the pearls of the Celebes are noted for their lovely colouring, while Australian waters yield pearls of a beautiful silvery white that are produced by *Meleagrina margaritifera* and *Meleagrina maxima*. The islands of the South Pacific also produce fine pearls, and the islanders are noted for their skill and daring as pearl divers. They use no sinkstone and both men and women take part in the fishing. In the Americas, salt-water pearls greater in size than oriental pearls, though less finely formed, have been fished in the Caribbean. The Gulf of California, the Gulf of Mexico and the waters of Mexico's Pacific coast have yielded dark-hued pearls with a metallic sheen, as well as white pearls of good quality.

Fresh-water mussels, notably the species known as *Unio margaritifera*, which inhabit the rivers and streams of the temperate zone of the northern hemisphere, have produced pearls of great value. The fresh-water pearls of the United States have come principally from the Mississippi river and its tributaries, although rivers in other parts of the country have been rich sources also. The most famous of all American fresh-water pearls, the pink "queen pearl," which weighed 93 pearl grains (23¼ carats), was found in Notch brook near Paterson, N.J., in 1857. It was purchased by the jeweler C. L. Tiffany, from whom it passed to a French gem dealer and was sold to the empress Eugénie.

Although pearling has declined greatly in Great Britain, pearls from the rivers of Scotland, particularly the Spey and the Tay, and those from the river Conway in northern Wales were once in great demand. Pearling is still a profitable and carefully fostered industry in central Europe, however, and the forest streams of Bavaria,

in particular, are the source of choice fresh-water pearls.

In China, fresh-water pearling is an ancient industry. As long ago as 2000 B.C., the pearl was a reckoned item in the collection of taxes or tribute, and it is listed in *Rh'y*, a dictionary believed to have been compiled earlier than 1000 B.C., as a product of the western part of the empire.

Cultured Pearls.—To the Chinese belongs the distinction of having been the first producers of cultured pearls. The discovery that pearl production in the fresh-water mussel could be stimulated by introducing a foreign object inside the creature's shell is said to have been made by Ye-jin-yang, a native of Hoochow, in the 13th century A.D. Certainly the Chinese have been adept for hundreds of years at cultivating pearls by opening the mussel's shell and inserting into it small pellets of mud, or tiny bosses of wood, bone or metal, and returning the mussel to its bed for about three years to await the maturation of a pearl formation. Curious pearl-encased statues of the seated Buddha have been produced by placing tiny metal statues of Gautama inside the shells of mussels. The cultured pearls of China have been almost exclusively blister pearls that required the addition of a half sphere of mother-of-pearl to achieve the joined round pearl form known as the doublet.

The production of whole cultured pearls was perfected by the Japanese; the research that led to the establishment of the industry was started in the 1890s by K. Mikimoto. After long experimentation, Mikimoto concluded that a very small mother-of-pearl bead introduced into the mollusk's tissue was the most successful stimulant to pearl production. It possessed the added virtue of providing a pearl entirely of nacreous content.

Cultured pearls closely approximate natural pearls. However, if the covering of nacre is too thin it will deteriorate upon prolonged contact with the human body and eventually will reveal the mother-of-pearl matrix. Japan has more than 300 sea farms devoted to production of cultured pearls. The largest of these extends for 20 nautical miles in Ago bay.

Examinations.—Numerous scientific instruments are available for ascertaining the nature and quality of a pearl. The core of a pearl can be observed in the strong light of the nacrescope, or pearl illuminator. Another instrument, the endoscope, provides an enlarged image of the hole drilled through the pearl for stringing. When the illuminator is used with the endoscope, the beam of light, which is first directed on the walls of the drill hole and then follows a path through the pearl, reveals the structure of the pearl from its heart out. The genuine pearl is of concentric construction, while the cultured pearl is shown to be composed of parallel layers of nacre upon its mother-of-pearl matrix. In the case of undrilled pearls, X-ray photographs aid the gem expert in determining the nature of the pearl structure.

Properties.—The colour of pearls varies with the mollusk and its environment. Colours range from black to white, with the rose of Indian pearls being valued most highly. Other colours are cream, gray, blue, yellow, lavender, green and mauve. All occur in delicate shades.

The size range also is wide. Pearls weighing less than one-quarter grain are called seed pearls; as many as 9,000 seed pearls may together weigh one ounce. The largest naturally occurring pearls are the baroques; Henry Thomas Hope owned a baroque weighing 1,860 gr.

Special care must be accorded pearls since they are comparatively soft and easily damaged by acids. On Mohs' scale of hardness, pearls are ranked as 3½ to 4, compared with 1 for talc and 10 for diamonds. This ranking indicates pearls can be scratched with a pin, coin or knife. Consequently they are worn almost exclusively in protected positions, such as in earrings and as necklaces. Pearls also can be damaged by friction; to avoid enlarging the drill holes, pearl necklaces should be restrung regularly and knotted between pearls to keep them from sliding on the string. Since pearls are composed mainly of calcium carbonate, they should not be placed in contact with acid; small amounts of weak acid occur in perspiration, hence pearls should be wiped off after being worn. Small amounts of acid may cause pearls to change colour; large amounts may cause them to decompose. Pearls also are adversely affected by heat.

The surface of a pearl is rough to the touch. A common method for distinguishing between natural or cultured and imitation (man-made) pearls is to pull a string of them across the teeth. The natural or cultured pearls feel rough; the imitation pearls feel smooth. Imitation pearls, which were first made in France in the 17th century, are manufactured by dipping alabaster glass beads in a pearl solution of fish-scale essence and lacquer and repeating until the desired qualities are attained.

History.—The history of the pearl is a long one. It is mentioned in the literature of ancient India as well as that of China (see *Sources of Natural Pearls* above). In Vedic literature the pearl is mentioned as being known in India before the influx of the Aryans (*c.* 1500 B.C.). Archaic Greek and Etruscan jewelry (*c.* 400 B.C.) featured borders of pearls surrounding a central setting of coloured gem stones. Fine pearls were fished in the Persian gulf when Macedonia was a power, and pearls were prized gems in imperial Rome. Oriental pearls were not widely known in medieval Europe until trade with the east was restored by the maritime city-states of Italy, when they became increasingly popular with Europeans. Both river and oriental pearls were used profusely for personal adornment. During the Renaissance, airily light earrings were made by suspending pearls from fine gold wires, and brooches were fashioned with pendant pearls. Portraits of the period show ropes of pearls encircling the neck and winding around the shoulders of the wearer. The goldsmith of the Renaissance found beauty in the baroque pearl. His imagination saw in it not the misshapen product of a sea mollusk but rather an animal form from nature, or the body of a hero or a god from the pages of classical mythology. He broke with the ancient tradition that demanded of the pearl the classic regularity of the sphere and skilfully incorporated the baroque into the individualistic freedom of his design.

With the advent of the modern era, pearls lost none of their popularity. The age turned to the safety of symmetry, however, and the regularity of the globed jewel was again preferred to the eccentricity of the baroque.

Pearls noted for their size, beauty and historical associations are ranked among the famous jewels of the world. La Reine des Perles, a 27.5-carat oriental pearl, was among the crown jewels of France stolen in 1792, while La Regente, an oval pearl weighing 34 carats, once was owned by the French imperial court. A beautiful Caribbean pearl presented to Philip II of Spain in 1570 is presumed to have been destroyed by fire in the Escorial in 1734.

PEARL HARBOR ATTACK. The Japanese attack on Pearl Harbor, Hawaii, on Dec. 7, 1941, was the culmination of worsening relations between the United States and Japan extending over a decade. U.S. policy in the far east was closely tied to friendship with China and to dislike of Japanese aggression against that state. As early as 1931 the Tokyo government had extended its sway over the Chinese province of Manchuria. By 1937 it had entered upon formal warfare with the Chinese Nationalists. In 1938 the United States government extended its first loan to China; in 1939 it denounced the commercial treaty of 1911 with Japan; in the summer of 1940 it began to restrict the export to Japan of materials useful in war. Between June 1940 and the fateful crisis of Dec. 1941, the tension constantly mounted. In July 1941, by which time the Japanese had occupied all of Indochina and had entered into an alliance with Germany and Italy, the U.S. government severed all commercial and financial relations with Japan. The militarists in the Tokyo government were steadily gaining in influence; they bitterly resented U.S. aid to China, which had by this time been stepped up; and they saw in the German invasion of the U.S.S.R. an unrivaled opportunity to pursue a policy of aggression in the orient without danger of an attack upon their rear by the forces at the disposal of the Kremlin. Nonetheless, negotiations looking to some kind of understanding between the United States and Japan took place

through the autumn of 1941, and not until near the end of November did it become clear that no agreement was possible. By this time the Japanese government had decided that upon failure of the negotiations, it would attack the United States without first declaring war; the plan for a surprise assault on Pearl Harbor had already been worked out. The order for this assault was issued on Nov. 5; on Nov. 16 the task force of about 30 ships, including 6 aircraft carriers, under Vice-Adm. Chuichi Nagumo, began its rendezvous in the Kuril Islands; and on Nov. 26 it sailed on its mission. It was instructed, however, that it might be recalled in case of a favourable outcome of the negotiations in Washington, D.C.

Warnings and Responses.—The U.S. Pacific force had been stationed at Pearl Harbor since April 1940. In addition to nearly 100 naval vessels, including 8 battleships, were substantial military and air forces at this key U.S. base. As the tension mounted, Adm. Husband E. Kimmel and Lt. Gen. Walter C. Short, in command at Pearl Harbor, were warned of the possibility of war, specifically on Oct. 16 and on Nov. 24 and 27. The dispatch of Nov. 27, to Admiral Kimmel, beginning, "This dispatch is to be considered a war warning," went on to say that "negotiations have ceased," and directed the admiral to "execute an appropriate defensive deployment." Kimmel was also ordered to "undertake such reconnaissance and other measures as you deem necessary." The communication of the same day to General Short declared that "hostile action is possible at any moment," and, like its naval counterpart, urged "measures of reconnaissance."

In response to these warnings, the measures taken by the army and navy commanders were, as the event proved, far from adequate. General Short ordered an alert against sabotage and concentrated most of his fighter planes at the base on Wheeler field in order more effectively to prevent damage to them. He also gave orders to operate five of the mobile radar sets that had been set up in the island from 4 A.M. to 7 A.M., considered to be the most dangerous period. (Radar training, however, was in a far from advanced stage.) Admiral Kimmel, despite the fact that his intelligence had not been able to locate substantial elements in the Japanese fleet, especially the first-line ships in carrier division 1 and 2, did not expand his reconnaissance activities to the northwest, the logical point for an attack. He moored the entire fleet (save that part which was at sea) in harbour, and permitted a part of his personnel to go on shore leave. Neither of these officers suspected that the base at Pearl Harbor would be subjected to attack. Nor, for that matter, is there any indication that their superiors in Washington were in any way conscious of the approaching danger. In the ten days between the war warning of Nov. 27 and the Japanese attack itself no additional action was taken by Washington.

Early on Sunday morning, Dec. 7, Washington learned that the Japanese ambassadors had been instructed to ask for an interview with the secretary of state at 1 P.M. (7:30 A.M. Pearl Harbor time). This was a clear indication that war was at hand. The message took some time to decode. It was not in the hands of the chief of naval operations till about 10:30. It was delivered at the war department between 9 and 10 A.M. General Marshall, the chief of staff, was out horseback riding and did not see the dispatch till arriving at his office about 11:15 A.M. The chief of naval operations, Admiral Stark, even then, did not think that the communication called for any additional instructions to Kimmel. However, General Marshall *did* decide to send a new warning, and gave orders to the military command to communicate also with the navy. He did not telephone, fearing that his words might be intercepted. He sent his dispatch by telegram. There was a mix-up in communication, and the warning did not reach Hawaii till after the attack had begun. It is important to note that it had not been filed until noon, only an hour before the Japanese planes moved in on the great base.

At Pearl Harbor itself, there were incidents that, properly interpreted, might have given a brief warning. Four hours before the decisive moment a Japanese submarine was sighted by the destroyer U.S.S. "Ward". No report was made. About two and a half hours later, the commander of the U.S.S. "Ward" sent a message saying that he "had attacked, fired upon and dropped depth charges upon submarine operating in defensive sea area." While Admiral Kimmel waited for "confirmation" of this report, the Japanese opened hostilities. In these same morning hours, an army private, practising on the radar set after its normal closing time, noticed a large flight of planes on the screen. When he telephoned his lieutenant, he was told to forget it, for a flight of B-17s from the United States was expected at that time. Once again, an opportunity was missed.

The Attack.—It was at 7:55 A.M. (local time) that the first dive bomber from the Japanese aircraft carrier arrived over Pearl Harbor. It was followed by a massive group of nearly 200 aircraft, including torpedo planes, bombers and fighters. Within a quarter of an hour the various airfields at the base were subjected to savage attack. At Wheeler field, in particular, where General Short had drawn up his planes, the destruction was fearful. Of the 126 planes on the ground, 42 were totally destroyed, 41 were damaged, and only 43 were left fit for service. Only six U.S. planes got into the air to repel the attackers on this first assault. At the same time a massive movement was directed against Admiral Kimmel's fleet, so conveniently moored at the base. The battleship U.S.S. "Arizona" blew up with a tremendous explosion.

U.S. NAVY PHOTO FROM U.P.I. COMPIX

BATTLESHIPS DURING ATTACK BY THE JAPANESE

(Left) U.S.S. "West Virginia"; (centre) U.S.S. "Tennessee"; (right) U.S.S. "Arizona." The "Arizona" and the "West Virginia" sank in the harbour with large loss of life

The U.S.S. "West Virginia" was riddled with bombs and torpedoes, and settled on an even keel on the bottom of the harbour. The old U.S.S. "Oklahoma," hit by four torpedoes within five minutes, rolled completely over, with her bottom and propeller rising above the waters of the harbour. The old target ship U.S.S. "Utah" was sunk. Hardly a vessel escaped damage. The antiaircraft crews on the various vessels were fairly prompt in getting into action; the army fired away with what it had; but the force of the attack was in no serious way blunted.

At 8:50 A.M. the second wave of the attack began. Less successful than the first, it none the less succeeded in inflicting heavy damage. The battleship U.S.S. "Nevada" was hit by seven or eight bombs and was grounded at the head of the channel. The battleship U.S.S. "Pennsylvania" was hit and the two destroyers moored near her reduced to wrecks. The destroyer U.S.S. "Shaw" was split in two by a great explosion. Shortly after 9 A.M. the Japanese withdrew.

No one could doubt that the Japanese had gained a great success. They had inflicted on the U.S. navy casualties to the number of 2,718, of which over 2,000 were fatalities. Army casualties exceeded 600 men, of whom more than 200 were killed. The attack had resulted in the total destruction of three battleships, in the capsizing of a fourth, in heavy damage to a fifth, and in lighter damage to three others. Two light cruisers were heavily damaged, and a third suffered less severe hurt. Three destroyers were put out of action, a repair ship badly punished, and a mine-

layer sunk. Heavy damage was inflicted on both army and navy planes on the ground. To accomplish these results the Japanese had sacrificed less than 100 men, 29 planes and five midget submarines. Their task force escaped without being attacked.

There was, however, one consoling feature to the tragedy. As a result of the dispositions made by Admiral Kimmel, two aircraft carriers were not in the harbour; they were engaged in reinforcing other stations, notably Midway and Wake islands. In connection with this same operation, seven heavy cruisers and a division of destroyers were at sea. Of cardinal importance was the absence of the carriers. They were the only two vessels of this type in the area, and were to play a highly important role in future battles.

Investigations and Interpretations.—The great disaster at Pearl Harbor led to numerous investigations. Almost immediately after the assault, the president appointed a commission headed by Justice Owen J. Roberts of the supreme court to examine the facts and to fix responsibility for the disaster. At a later date both army and navy boards reviewed the problem. In 1946 a full-scale congressional investigation took place. Probably no episode in U.S. military history has been so thoroughly examined, and on none has a wider divergence of opinion been expressed.

The most extreme view of the disaster is not to be found in any of the numerous investigations, but was disseminated long after the tragedy by Rear Adm. Robert A. Theobald of the U.S. navy in *The Final Secret of Pearl Harbor*. This view is that President Roosevelt "by unrelenting diplomatic pressure" "enticed" Japan "to initiate hostilities with a surprise attack by holding the Pacific fleet in Hawaiian waters as an invitation to that attack." Such a position is not taken by any responsible historian. It involves judgments as to motives which simply cannot be substantiated.

The president did indeed pursue a policy of support to Nationalist China which acted as a substantial irritant to the Tokyo government, and did much to provoke it to action. But at the same time there is substantial evidence that he sought to postpone a clash, rather than to incite one, and even in the closing days of the negotiations he made an appeal to the Japanese emperor, which, if listened to, might have had that effect.

The success of the attack on Pearl Harbor was primarily due to a false estimate of the enemy's capabilities and intentions. The authorities in Washington knew that the Japanese forces were moving southward into the Gulf of Siam. They did not believe that coincident with this move they could or would mount an attack on the Hawaiian base. It seemed logical, too, that the Japanese would avoid such action because it would inevitably bring the United States into the war; operations in the far east directed against the British and the Dutch might not have this effect. True, the possibility of an air attack on Pearl Harbor had been frequently discussed in the course of the year. But, as matters came to a crisis, for the reasons mentioned above, it fell into the background.

It is a difficult matter (and one on which divergent opinions will long be held) to apportion responsibility between Washington and the commanders on the spot. The Roberts commission, the body appointed by the president on Dec. 17, 1941, in a report presented only a few weeks later, placed the principal blame for the disaster upon Admiral Kimmel and General Short. The army and navy commissions which later examined the problem took a contrary view, throwing the blame on the war and navy departments. The majority report of a congressional committee, rendered in 1946, while not avoiding criticism of the chief of naval operations and the army chief of staff, laid stress on the lack of preparation in Hawaii. Two members of this committee strongly dissented, severely blaming the authorities in Washington, and a third took a kind of middle ground.

Those who defend the position of the Hawaiian commanders make the following points. General Short replied to Marshall's warning of Nov. 27, "Department alerted to prevent sabotage." When this reply passed over the chief of staff's desk, he neglected to notice that it mentioned only this one kind of preparation (as did Gen. Leonard T. Gerow, his subordinate). At no time in the next ten days was this neglect repaired. As for Admiral Kimmel, the point has been made that he was inadequately informed as to the seriousness of the crisis. In the months before Pearl Harbor the armed services, through the breaking of the Japanese code, were able to get much information as to Japanese purposes. Not a small part of this related to the position of the naval forces in Hawaii. Kimmel himself has claimed that had he been put in possession of this material he would have taken far stronger measures than he actually did. In defense of his failure to undertake more vigorous measures of reconnaissance, he urged the importance of his training program, and the limited nature of his resources.

The critics of Washington also asserted that by the evening of Dec. 6 the president had clear evidence that war was impending, and that he should have taken prompt measures to alert the war and navy departments. This view attached little importance to the warnings of Nov. 27.

Those who were critical of the commanders on the spot took the view that the warnings given were sufficient, and that a deplorable lack of imagination was shown in acting on them. Everyone who read the papers knew that war was imminent. Why was not the possibility of an air attack taken into account? Why were Short's airplanes drawn up in such fashion as to be most exposed to enemy attack? Why was the radar training program not more advanced? Why did Admiral Kimmel so handle his schedule that the Japanese could count on all the battleships being in port on Sunday? Why were normal week-end leaves and liberties granted? Why was not some attempt made to improve reconnaissance? Why was not the report on the Japanese submarine taken more seriously? Those who emphasize the responsibility of Kimmel and Short also call attention to the fact that the war warnings of Nov. 27 brought much more vigorous action on the part of the commanders in the Canal Zone and the Philippines.

Whatever judgment may be rendered on this matter, more important than the question of responsibility is the question of the historical significance of Pearl Harbor. And here the verdict is easier to come at. Great as was the Japanese success in the short run, great as was the humiliation inflicted on the United States, the "sneak attack," in the longer perspective, was a monstrous error on the part of the government in Tokyo. Even from the tactical point of view it was a blunder. For in their purpose of destroying the fleet, the Japanese neglected the great oil supplies on Hawaii, the destruction of which would have immobilized the United States for months to come. But, more important, the Japanese attack brought the U.S. government into the war, unified the American people, and made the ultimate defeat of the Japanese militarists inevitable. There was much antiwar sentiment in the United States in the fall of 1941. Had the Japanese commanders directed their attention against the British and Dutch, it must have been at least doubtful whether President Roosevelt could have led the American people into the war in the Pacific. As in so many other instances in the history of the 20th century, in spite of the weaknesses of the democracies, the autocratic states made errors even more vital than the errors of the democracies. Pearl Harbor was atoned for in four and a half years of war; but the blunders of the Tokyo militarists resulted in utter and total defeat. This is the most memorable fact of all with regard to the "sneak attack" of Dec. 7, 1941.

BIBLIOGRAPHY.—The most voluminous source of material on the Pearl Harbor attack is the hearings of the Joint Committee on the Investigation of the Pearl Harbor Attack, 79th Cong., 1st. Sess. (39 vols.) followed by the report of the committee itself, 79th Cong. 2nd. Sess. Doc. 244. There are to be found the report of the Roberts Commission, the Army Pearl Harbor Board, the Naval Court of Inquiry, and the Hewett Inquiry, with masses of testimony as to the attack itself. Of secondary materials the following may be mentioned. Walter Millis, *This is Pearl! the United States and Japan, 1941* (1947); Walter Lord, *Day of Infamy* (1957); Rear Admiral Robert A. Theobald, *The Final Secret of Pearl Harbor* (1944); Admiral Husband E. Kimmel, *Admiral Kimmel's Story* (1955); George E. Morgenstern, *Pearl Harbor: The Story of the Secret War* (1947); Charles A. Beard, *President Roosevelt and the Coming of the War, 1941* (1948); R. Wohlstetter, *Pearl Harbor: Warning and Decision* (1962). An admirable brief analysis is to be found in Samuel Eliot Morison, *The Rising Sun in the Pacific* in vol. 3 of his History of United States Naval Operations in World

War II (1948); and in Mark S. Watson, *Chief of Staff: Prewar Plans and Preparations*, pp. 494–520 (1950). The three volumes by Theobald, Kimmel and Morgenstern are distinctly polemical, and should be used with caution. Charles A. Beard's account is also slanted, but contains much material of great interest on the various hearings. (D. Ps.)

PEARL RIVER, a river of the southeastern United States, rises in east-central Mississippi, near Louisville, and flows southwest, south, and then slightly southeast to the head of its delta, south of Bogalusa, La. From there the East Pearl river continues southward for 34 mi. (55 km.) and passes into Mississippi sound near Grand Island. West Pearl river parallels East Pearl in the delta, several miles to the west, and enters the Rigolets, a tidal channel connecting Lake Pontchartrain with Lake Borgne. The two mouths of the Pearl are interconnected by a maze of channels.

The Pearl is approximately 490 mi. (789 km.) long and has a drainage basin of about 7,600 sq.mi. (19,684 sq.km.). Chief tributaries are the Yokahockany and Strong rivers and the Bogue Chitto. Three locks on the West Pearl, completed in 1953, provide a 7-ft. channel from the mouth to Bogalusa, 58 mi. (93 km.) upstream. Navigation on the East Pearl and on the Pearl above Bogalusa is no longer important. Until the early 20th century, however, the river below Jackson, Miss., was a main route for transporting lumber. Columbia, Monticello and Jackson, Miss., and Bogalusa, La., are the chief river cities. Jackson obtains its water supply from the Pearl. In 1958, the Mississippi legislature approved the issuing of revenue bonds for a 21-mi.-long (34 km.) reservoir north of Jackson, to provide water, flood and pollution control and recreational facilities for the Pearl River valley.

The lower course of the Pearl, and the East Pearl, form the boundary between Mississippi and Louisiana. Prior to 1812, when Louisiana was granted statehood, the Pearl was the eastern boundary of the province of West Florida. Honey Island swamp lies in the mid-delta area of the Pearl River valley, southwest of Picayune, Miss. This heavily forested swamp, criss-crossed by a maze of channels, is noted for its wildlife and fishing. (M. W. M.)

PEARSE, PATRICK HENRY (1879–1916), Irish revolutionary nationalist and poet, and a leader of the Easter rising in Dublin in 1916, was born in Dublin on Nov. 10, 1879, the eldest son of James Pearse, an English monumental sculptor, and of his Irish wife Margaret Brady. Educated at the Christian Brothers' Schools, Dublin, and the Royal University of Ireland, Pearse joined the Gaelic League, becoming an energetic member of its executive, and was editor of its weekly publication *An Claidheamh Soluis* from 1903 to 1909. He wrote later that the Gaelic League "will be recognized in history as the most revolutionary influence that has ever come into Ireland." Pearse wanted an Ireland free from foreign domination and influences. He published tales from Irish manuscripts and in 1914 a celebrated collection of poems in the modern Irish idiom. Deeply interested in education, he toured Belgium to study bilingual methods and he approved of Augustine Birrell's Irish educational policy, since it gave Ireland control over its own educational system. He founded St. Enda's College at Cullenswood, Dublin, in 1908, as a bilingual college with its teaching based on Irish traditions and culture. In 1910 it was moved to the Hermitage, Rathfarnham. Pearse outlined his ideas on education in an essay, "The Time Machine" (1912), and in *The Story of a Success . . . a Record of St. Enda's College* (1917).

On the formation of the Irish volunteers in November 1913 (*see* IRELAND: *History*), Pearse became a member of the provisional committee and in July 1914 was made a member of the supreme council of the Irish Republican brotherhood. He wrote poems and articles for *The Irish Volunteer*, the official paper of the volunteers, as well as pamphlets designed to stir the minds of the people and to prepare them for a national uprising. After the Irish volunteer movement split in September 1914 he became director of organization of the more extreme Nationalist section, which opposed any support for Great Britain in World War I. He was moved most of all by a burning conviction that Ireland might be freed only by the blood of martyrs and his oration in August 1915 at the graveside of O'Donovan Rossa, the veteran Fenian, was a classic of romantic revolutionary eloquence on this theme. Commander in chief of the Irish forces at the rising in Dublin on Easter Monday, April 24, 1916, Pearse proclaimed the provisional government of the Irish Republic, of which he was the first president, from the steps of the general post office. He surrendered on April 29, 1916, and after a military court martial was executed by a firing squad at Kilmainham Prison, Dublin, on May 3, 1916. More than any other man, Pearse was responsible for establishing the republican tradition in Ireland. His *Collected Works* were published in three volumes (1917–22) and in five volumes (1924); his *Political Writings and Speeches* were published in 1952.

See L. N. Le Roux, *Patrick H. Pearse*, Eng. trans. by D. Ryan (1932). (P. N. S. M.)

PEARSON, KARL (1857–1936), British mathematician, one of the founders of modern statistics, was born in London, March 27, 1857, and educated at University College School, London, and Kings College, Cambridge. He practised law from 1881 to 1884, when he received an appointment as professor of applied mathematics and mechanics at University College, London. There he taught until his retirement in 1933, becoming lecturer in geometry (1891), head of the department of applied mathematics (1907), and professor of eugenics (1911). Pearson was the founder and editor (1902–36) of the statistical journal *Biometrika*, editor of *The Annals of Eugenics* (1925–36), and director of the Biometric and Francis Galton Eugenics laboratories.

Pearson's early lectures were published as *The Grammar of Science* (1892), one of the classics in the philosophy of science. Beginning in 1890 his interests began to shift to the application of statistics to biological problems of heredity and evolution; his greatest contribution was the methodology he developed for the handling of certain types of problems in the biological and social sciences. From 1893 to 1912 he wrote a series of 18 papers entitled *Mathematical Contributions to the Theory of Evolution*, which contained much of his most valuable work, including the chi-square test of statistical significance. He died on April 27, 1936, in London.

Among his other works were *The Ethic of Free Thought* (1888); *The Chances of Death and Other Studies in Evolution* (1897); *The Life, Letters and Labours of Francis Galton* (1914, 1930); *Tables for Statisticians and Biometricians* (1914, 1931); *Tables of the Incomplete Gamma Function* (1922); and *Tables of the Incomplete Beta Function* (1934).

See also E. S. Pearson, *Karl Pearson* (1939); H. M. Walker, "Contributions of Karl Pearson," *American Statistical Association Journal*, vol. 53 (March 1958). (S. S. W.; X.)

PEARSON, LESTER BOWLES (1897–), Canadian statesman, Liberal Party leader and prime minister, who won the Nobel Peace Prize in 1957. He was born at Toronto, Ont., on April 23, 1897. He was educated in the public schools of Peterborough and Hamilton, and served in World War I in the Royal Flying Corps. Invalided home, he entered the University of Toronto (B.A., 1919) and earned B.A. and M.A. degrees at Oxford University (1923, 1925). He was a lecturer (1924–26) and assistant professor (1926–28) of history at the University of Toronto before becoming a first secretary in Canada's newly formed Department of External Affairs. After a series of diplomatic posts and service on loan as secretary to two royal commissions, he became secretary (later counsellor) of the Canadian High Commissioner's Office in London. Canada's ambassador to the United States, 1945–46, and undersecretary of state for external affairs, 1946–48, he was often spokesman for Canada at the United Nations. He served in 1947 as chairman of the UN Political and Security Committee of the UN General Assembly. In 1947 he was instrumental in securing UN passage of the Palestine partition resolution.

He entered politics in 1948, becoming secretary of state for external affairs in the Liberal government of Louis St. Laurent and member of Parliament for Algoma East. Reelected three times, he became a private member of the House of Commons in opposition when his party was defeated in June 1957. He was awarded the Nobel Prize for his efforts at resolving the 1956 Suez crisis. In 1958 he succeeded St. Laurent as leader of the Liberal Party and in April 1963 became prime minister. (W. D. A. O'H.)

PEARY, ROBERT EDWIN (1856–1920), U.S. Arctic explorer who reached the North Pole in 1909, was born at Cresson,

Pa., on May 6, 1856. He was graduated from Bowdoin College, Brunswick, Me., then joined the civil-engineering branch of the U.S. Navy and took part in the survey of the Nicaragua canal route from 1885 to 1887. In 1886, with one companion, he journeyed inland from Disko Bay over the Greenland ice sheet for about 100 mi., reaching 7,500 ft. above sea level. He returned in 1891 with seven companions, including his wife and F. A. Cook. After wintering in Hvalsund, he sledged for 1,200 mi. to the northeast of Greenland, discovering Independence Fjord and evidence of the insularity of Greenland. The "Arctic Highlanders," an isolated tribe of Eskimo, were befriended and studied; they were of the greatest assistance to Peary on later expeditions. He returned to Hvalsund in 1893 with a larger party, and sledging journeys were made to northeast Greenland again in 1894. Summer trips in 1896 and 1897 were mainly occupied in transporting three masses of meteoric iron from Greenland to the United States. In 1898 he announced his intention of reaching the North Pole, and from 1898 to 1902 he reconnoitred routes from bases at Etah in Inglefield Land and Fort Conger on Ellesmere Island. Meanwhile, the Peary Arctic Club of New York was formed to raise funds for the support of his further expeditions, thus relieving Peary of financial worries. A ship, the "Roosevelt," was built to his specifications and carried his next expedition, early in 1905, through Smith Sound to Cape Sheridan, Ellesmere Island. The sledging season was unsuccessful owing to adverse weather and ice conditions and the party only reached latitude 87° 6′ N. Peary returned to Ellesmere Island in 1908 and early the following March left Cape Columbia on his successful journey to the North Pole. He was accompanied on the last stage of the journey by Matthew Henson, his Negro aid, and four Eskimos, one of whom was drowned during the return. F. A. Cook's claims to have forestalled him by a year, though generally discredited, marred the enjoyment of Peary's triumph. He died on Feb. 20, 1920, in Washington, D.C. Peary's published works include *Northward over the "Great Ice"* (1898), *Nearest to the Pole* (1907), *The North Pole* (1910), and *Secrets of Polar Travel* (1917). (L. M. Fs.)

PEASANT MOVEMENT. World War I and, paradoxically, the Russian Revolution gave a strong impetus to the political consciousness of a class which had seemed to be falling into insignificance. Through the centuries the peasants had occasionally played a forceful part in social convulsions, but since the Industrial Revolution western political life was dominated by leaders in commerce and industry; and that trend was only sharpened by the rise of the workers' movement. Eastern Europe had little industry: the bulk of its people were peasants, who had little share of material wealth and little influence in public life. And so it was natural that the stirrings of 1917 in that region should raise a peasant movement, with a social and political philosophy all its own.

Political Traditions of the Peasantry.—Between the French Revolution and 1848 the peasants of western and central Europe were gradually freed from all feudal servitudes. But the peasants derived only an indirect benefit from reforms achieved mainly by the urban middle classes, who needed freedom of action for the new capitalist enterprise.

The growing division between town and country was widened into a gulf by the rise of "scientific" socialism. The viewpoint of socialist economics was essentially the same as that of capitalist liberalism, except that the socialists wanted production to be planned, organized and controlled upon the largest scale. Marx gave credit to capitalism for having at least rescued considerable sections from the "idiocy of rural life"; he and his disciples placed the nationalization of the land and collectivised farming in the forefront of their program. This gave rise to the organization of many conservative agrarian groups in central and western Europe, which found in the peasants credulous recruits. The electoral effects gradually led to a watering down of socialist agrarian programs.

Populism.—The economic and political incentives which had interested the western bourgeoisie in rural emancipation had little meaning in the eastern half of the continent. Politically, that region was still in the autocratic stage. Its economic life rested on primitive agriculture and artisan manufacture. But the social incentive stirred up reformers in the east perhaps more deeply than in the west.

The younger intellectuals, imbued with 18th century humanitarian philosophy, centred all their ideals on freeing the peasants. But what for western liberals had been an end in itself, for the Russian reformers was merely a steppingstone to a free and full village life. Marxism was essentially a policy for transforming industrial society; in the east, socialism was for the peasants. Hence eastern socialists were forced to work out alternative ideas and programs suited to the problem of their own peasant populations. "Populism" became the expression of that trend. (*See* RUSSIA: *History.*)

The kernel of populism was the rejection of Marxist economic determinism. Marxism looked upon capitalist concentration of production as only a stage on the way to a socialist society. The Russian Populists put their faith in the existence of the village community (*mir*). They contended that a capitalist-proletarian phase was neither necessary nor possible in a backward agrarian country, as it would merely ruin the peasants, the only customers for industrial products. Above all, they believed that a rural democracy offered the masses the promise of a better life than industrial society. All they needed was more "land and liberty," and the backbone of the Populist program was a plea for the equal distribution of land among the peasants.

The later exponents of this program were the Social-Revolutionaries, the strongest party of the left up to the Bolshevik revolution. That the Populist doctrine had its roots in the natural conditions of the region is proved by the way it spread to the other agrarian countries of eastern Europe. It was perhaps natural that Serbia and Bulgaria should come under its influence, for both stood intellectually in close dependence on Russia. The decisive test is supplied by Rumania, a Latin country, strongly averse to Slav influence, yet there also the new doctrine engendered a strong rural current that joined with the others in denouncing Marxism.

The Peasant Renascence.—The Populist movement had remained largely theoretical because the peasants were restrained by a rigid political and social tutelage. Political activity and claims for the distribution of land were treated as revolutionary activity. The only outlet for their grievances were occasional uprisings, like those of 1905 in Russia and 1907 in Rumania, which were mercilessly repressed. But World War I and the Russian Revolution completed in the east the change begun by the French Revolution in the west. Sweeping reforms transferred the bulk of the land to the peasants, thus holding out to them the hope of economic independence. At the same time the peasants secured political rights, and were roused to a consciousness of their interests and their power as a class. Their movement was still loose and vague: its possibilities lay in the fact that more than half the population of the globe lived under a typically peasant "family economy," and that even in Europe there were more peasants than industrial workers.

In India the Congress party was led to take over the program of the Kisan Sabhas which had come into being after the 1930s; in China the strength of the Communist movement derived largely from its support of the peasants. There were stirrings in other far eastern countries, and also in South America and the middle east.

Doctrine and Program.—Unlike socialism, which had a fully developed doctrine before it had an organized following, the peasant movement sprang up separately in the various countries, though out of similar convulsive events. Hence its sociology was still in the making, and the programs of the several parties showed substantial variations. Its philosophy and policy were taken over and adapted to its own use elements from all the main political creeds. It can be summed up as a cross between liberalism and socialism: it stands firmly for democratic government and it holds tightly to the small family holding, which to the peasant is not merely a means of living but a way of life. For the rest, it generally accepts state control of public services and of primary and other big industries, though it wants small

industries scattered about the country to combine work on the land and in the factory according to seasonal needs. It is generally anticapitalist, but would eliminate bankers and middlemen gradually by setting up co-operatives either for specific purposes or embracing the whole life of a village community. It believes in a rural society based on an educated, land-owning peasantry; and combining through a network of co-operative undertakings the virtues of small property with the means of large-scale enterprise.

The radicalism of the eastern peasant movement came from the peculiar conditions of the region. In the west, agrarian parties were a mixture of all rural classes, with big landowners to the fore, as in the German *Landbund;* the eastern parties were exclusively peasant. Secondly, oppression in the east had prevented the growth of a peasant middle class, so the movement was supported by a more uniform mass of small peasants. Thirdly, peasant antagonism toward town and capitalism had different effects in the two halves of Europe. In the west, finance and industry had entered a phase of international organization by means of cartels, trusts, etc., and the outlook of the towns was cosmopolitan; as a reaction the countryside was conservative and nationalist. In the east, industry and finance were bound up with local nationalism, and the peasant who paid the bill of protectionism favoured a liberal and even a radical policy in all respects.

The Peasant Parties.—The peasant movement that sprang up after 1918 was peculiar to the eastern half of Europe. In the industrial countries of the west, even in the Netherlands and Denmark, the peasants had been drawn into conservative agrarian parties because of a general antagonism to industry and finance, partly through clerical influence, and largely by the fear of the socialist demand for land nationalization. But just as western socialism had stirred up industrial groups in the east and shaped their outlook, so the eastern peasant movement caused stirrings in the west. In France a peasant party was founded four weeks before the elections of 1928; in Germany, also before that year's elections, the left wing of the old *Landbund* formed a new Christian National Peasant party, and at the same time the Bavarian *Bauernbund* changed itself into a German Peasant party which dominated the parliamentary situation in Bavaria. Attempts to establish peasant parties were made in the Netherlands and elsewhere.

Some of the eastern peasant parties were founded before World War I, but became important only after it. The Bulgarian Agrarian union, founded in 1899 as a professional body, became political in 1901: it polled 14.45% of the votes in 1911, 31% in 1919, 38.16% in 1920, 52.0% in 1923. In June 1923 a military coup led to the murder of Aleksandr Stamboliski and other party leaders. While in power, the party carried through broad co-operative measures and a law for compulsory civic service (*see* International Labour organization pamphlet, *Legislative Series,* 1920).

The Czechoslovak Republican Party of Farmers and Small Peasants, founded in 1896, at first conservative, veered leftward, led by Antonin Svahla, Rudolf Beran, and Milan Hodza. Czechoslovakia took the lead in adopting an 8-hour day for agriculture and working out practical ties between peasant producers' co-operatives and urban consumers' co-operatives. Alone of the eastern countries, it included members of the national minorities in the cabinet. All these steps were due to the party's initiative.

Poland had several peasant parties, reflecting its unsettled political outlook. The Polish Populist party, known as *Piast* (significantly the name of the first Polish royal dynasty, which was of peasant origin) was led by Wincenty Witos. Twice premier, he was rather conservative, admitted land reform only with compensation, and was open to clerical influence. The Liberation party, led by Stanislaw Thugutt, was radical, demanded land reform without indemnity, favoured regional autonomy for the minorities, and was anticlerical. A similar program was supported by the Peasant party led by Jan Dabski, representing chiefly the small peasants.

It is noteworthy that while the political movement was divided by regional, clerical and personal influences, the peasants worked together in their co-operative affairs, brought to high achievement by Stanislaw Mikolajczyk. The Rumanian National Peasant party, formed by the fusion of several groups, was the only substantial opposition; in Nov. 1928 it formed the first truly parliamentary government in Rumania, led by Iuliu Maniu, Nicholas Lupu, Ion Michalache, and the economist Virgil Madgearu.

In Yugoslavia the Croat Peasant party, founded in 1904, dominated Croatia after World War I and gained strength in Bosnia and Dalmatia. Stjepan Radić, Pavle Radić, Dr. Vladimir Maček and other leaders held office in various coalition governments. Remarkable for its organization and comprehensive activities, and especially for its spiritual cohesion, it was built upon a clear rural creed rather than upon agrarian interests.

There were also rising peasant parties in Finland, the Baltic states and elsewhere.

International Organization.—A number of international agrarian bodies had existed before, but they had not been limited to peasant groups nor had they been set up for political action. Soon after World War I an attempt was made by Bavarian and Austrian farmers to unite the peasant groups of central Europe, the Bavarian Georg Heim being one of the initiators. The movement was conservative and anticommunist and, while some of the leaders kept neutral, others had a strong clerical bias. The attempt came to nothing. Though no peasant party existed in Russia, the Communists encouraged some of the refugees living in Moscow to set up there a Peasant International. Formed in 1923, it held its first congress in 1925, but made no visible impression on the peasant movement. On the initiative of the Bulgarian Stamboliski, an international bureau for research and information was set up in Prague in 1921, the Czech, Bulgarian, Polish and Serbian parties being members. In May 1928, the bureau was joined by the Croat, Rumanian and other parties, including the newly-formed French and Dutch parties. At the same time, eight parties of central and eastern Europe formed a regional group within the bureau itself with a joint executive, to work for the solution of political and social problems in the peasant interest; and to resist jointly any attempt at dictatorship, from the left or from the right.

The Interwar Period.—The potential strength of the eastern peasant movement was attested less by the actual power it enjoyed than by the strong efforts made to check it. As noted above, Stamboliski and other Bulgarian leaders were murdered in 1923 and the party broken up. The Croat leaders were repeatedly imprisoned, and ultimately Stjepan Radić died of wounds, and his nephew Pavle Radić and others were killed outright. The Rumanian leaders were persecuted and the party was denied the power to which its electoral strength entitled it.

In Poland, Witos was imprisoned for a short time and then had to flee the country. All these parties and leaders had stood firmly for democratic government and social reform. Their persecution everywhere ended in dictatorship, because the peasant groups also had to face the competitive antagonism of socialist parties. In Bulgaria, Rumania and Yugoslavia these were insignificant, but they were strong in Poland and Czechoslovakia. The division between the two sections of the working mass paved the way for reaction.

War and Aftermath.—World War II and the Nazi occupation found the peasants united with others in resistance; there was no defection among their groups and leaders. But after victory the movement again became the target of violent reaction, this time from the Communist left, backed by Russian military power. Against all Marxist teaching and Soviet policy, the new regimes in the eastern countries, including the Soviet zone of Germany, handed over the land to the mass of poorer peasants, in tiny uneconomic holdings, to undermine the solidarity of the peasant class. At the same time, all the peasant parties were suppressed, their leaders killed, imprisoned or driven into exile. The latter group revived in Washington, D.C., the activities of the International Peasant union in 1947. Significantly, in Poland, Bulgaria, Rumania, Hungary and Czechoslovakia, the Communist regimes found it expedient to set up new peasant parties under their own patronage.

Up to 1948 these regimes sought to keep the peasants quiet and at work by denying any intention to collectivise farming. But after 1948 collectivisation was pressed forward ruthlessly in all the "peoples' democracies." It was later pushed forward in China, where in 1948 the Communists had ridden to victory on the back of a discontented peasantry.

After Stalin.—This trend was sharply reversed after the death of Stalin. Nikita Khrushchev, who had formerly invented a scheme for the extreme concentration of farming in "agro-towns," took the initiative in lowering taxes, reducing the compulsory deliveries, and giving higher prices for produce taken from the peasants by the state. Admitting that central planning had proved "wrong and inefficient," a decree in March 1955 also gave collective farms more power to run their own affairs. In China, also, in March 1957 peasants were given some ease, but later, new oppressive measures sought to end peasant resistance.

The Soviet reversal set off a more thorough retreat in the satellite countries. Apart from concessions to the peasants in the form of lower prices and reduced taxes in Yugoslavia, Rumania, Hungary and Poland, the very policy of collectivisation was eased or virtually abandoned. In Poland, two thirds of collectivised farms were said to have been broken up and returned to individual holdings. In Indonesia and in Indochina the Communist leaders formally disclaimed any idea of nationalizing agriculture and promised to distribute land to the peasants.

The simple fact is that wherever the Communists gained power the Marxist agrarian idea had to be imposed by force and had to rely on force for its survival; western socialists who wanted to remain democratic in every instance had to abandon it. Whatever else the Soviet and other Communist regimes may have achieved, the agrarian problem has defeated them.

The peasants have not been allowed to revive their own parties, and no peasant has held office in the Soviet Politburo. But even in collectivised areas the peasants are still a class.

In the first general election of 1952 in India the Communists gained in depressed agricultural areas, not in cities. India began to experiment widely with a middle-of-the-way system of "community development." Side by side with essential heavy industries she encouraged cottage and village industries, and promoted agricultural improvement, with the village as a relatively self-contained economic and administrative (*panchayat*) unit. This policy followed closely the ideas of Gandhi, but it was also strikingly close to the outlook and program developed independently by the peasant movement in eastern Europe. It revealed how essentially peasant qualities are rooted in the peculiar conditions of rural work and life. As the peasant revival of the 1920s showed, the peasants of eastern Europe, and other continents, were more closely linked by common peasant traits than they were divided by national differences.

See David Mitrany, *Marx Against the Peasant* (1952). (D. Mi.)

PEASANTS' REVOLT. The Peasants' Revolt of 1381 was the first great popular rebellion in English history. The main causes of the rising were the collection of a poll tax at a rate of one shilling per head, and agrarian discontent that had existed since the time of the Black Death. Artisan support for the rebels was important in many places; probably the main grievance of agricultural labourers and the working classes in the towns was the attempt made in the Statute of Labourers, first enacted in 1351, to prevent increases in wages. The most serious disorders occurred in southeast England and in East Anglia, but there were widespread disturbances affecting many other counties, including Cambridgeshire, Hampshire, Somerset, and West Riding of Yorkshire. In some towns local conditions were decisive; at St. Albans and Bury St. Edmunds the townsfolk rose to end the rule of the abbot and to secure municipal freedom.

The rising took the government by surprise. At the end of May the outbreak, which began in Essex, soon spread to Kent and the ineffectiveness of the ministers ruling on behalf of the young Richard II enabled the Kentish rebels to enter London on Thursday, June 13. There they massacred some Flemish merchants and other aliens and destroyed the Savoy palace, the property of the king's uncle, John of Gaunt. The government was compelled to negotiate and in an interview with the men of Essex at Mile End on June 14 Richard II promised the abolition of serfdom and compulsory labour services, the leasing of bond land at a rent of 4*d.* per acre, and freedom of trade throughout the realm. During the king's absence at Mile End the Tower of London was surrendered to the mob; the chancellor, Archbishop Simon of Sudbury, and the treasurer, Sir Robert Hales, who were held responsible for the exaction of the poll tax, were both beheaded. The confiscation of church lands was among the demands made by the Kentish rebels at Smithfield on Saturday, June 15, but the insurgents dispersed after their leader, Wat Tyler (*q.v.*), had been struck down in the king's presence. Richard II's promises, which had persuaded many of the rebels to go home, were not kept after the collapse of the movement. The rising lasted less than a month and the crisis in London was over before the troubles in the provinces reached their climax. In East Anglia, where the leader was a dyer, Geoffrey Litster, the rebellion was crushed by the militant bishop of Norwich, Henry le Despenser, probably on June 25.

The rising was not a movement of men made desperate by destitution; among the rebels were many well-to-do villeins. Insofar as it aimed at social revolution, the insurrection was a failure and manorial discontent continued to find expression in local riots. As a protest against taxation of the poorer classes, the rebellion was successful, because it prevented any further attempt to levy the poll tax, first instituted in 1377. *See* also English History: *The 14th Century*.

Bibliography.—*The Anonimalle Chronicle, 1333–1381,* ed. by V. H. Galbraith (1927) contains the most valuable contemporary account of the revolt. *See* also A. Steel, *Richard II* (1941); C. W. C. Oman, *The Great Revolt of 1381* (1906); G. M. Trevelyan, *England in the Age of Wycliffe*, 4th ed. (1909); A. Réville, *Le Soulèvement des travailleurs d'Angleterre en 1381* (1898); C. E. PEAT: *see* Fuels: *Peat*.

PEĆ (formerly Ipek; ancient Pescium), a town of Kosovo i Metohija (Kosmet), Socialist Republic of Serbia, Yugos., lies in the foothills of the Prokletije (North Albanian Alps) Mountains, 389 km. (242 mi.) S of Belgrade by road. Pop. (1961) 28,297 including a large proportion of Albanians. A small stream, the Bistrica (Bistritza), flows through the town which, with its narrow streets and mosques, presents an oriental appearance. It is the terminus of a railway from Nis and a commercial centre for fruit and tobacco. Peć was formerly the chief see of the Serb Orthodox Church, the archbishopric having been raised to the patriarchate by Stephen Dushan (1331–55). This was suppressed in 1459, restored in 1557, and abolished again by the Turks in 1766. After the Turkish occupation the Serbs continued to emigrate from this region to the north, the greatest exodus taking place in 1690, led by the patriarch. The title of archbishop of Peć is still retained by the patriarch of Belgrade. In 1918 the town was incorporated in the Kingdom of the Serbs, Croats, and Slovenes (called Yugoslavia from 1929). The patriarchal buildings just outside Peć on the west include churches with fine 13th- and 14th-century frescoes. (V. De.)

PECAN, one of the finest nuts in flavour and texture, with the highest fat content of any vegetable product and a caloric value close to that of butter. Its production is the basis of a considerable industry in the southeastern United States. The pecan tree (*Carya illinoensis*, or *C. pecan*), a member of the walnut family (Juglandaceae), is the most important nut producer of the *Carya*, the hickory genus. It is the most important orchard species native to temperate North America, though a sizable portion of the industry is still in wild trees, some of them supporting grafts of selected varieties. The tree is the largest of its genus; in deep, fertile soils it occasionally reaches a height of about 160 ft. and a trunk diameter of 6 ft. It has a deeply furrowed bark; compound leaves with 9–17 finely toothed edge leaflets, arranged in feather fashion. The male (staminate) flowers form pendant catkins; the female (pistillate) flowers are arranged in tight clusters at the ends of shoots. At maturity the fleshy hulls of the short-clustered fruits dry, split along suture lines, and separate into four approximately equal sections, thus gradually freeing the nuts. The nuts have

brown, mottled shells, varying greatly in thickness; size varies from 45 to 200 per pound, and shape from long-cylindrical with pointed apex, to short and roundish, or intermediate. Harvesting begins in late September, but may continue until late winter in southern orchards.

The original range of the pecan tree may not have extended into the northern Mexican highlands before men took nuts there from Texas. Native trees have been found from near the Rio Grande in southwest Texas, north and east to extreme southeast Nebraska, eastern Iowa, west-central and southern Indiana, and occasionally up the Tennessee River to near Muscle Shoals in Alabama. Limited cultivation of grafted varieties had begun in Louisiana by 1847; some important varieties were introduced before 1890, and thereafter the crop assumed increasing commercial importance from the Carolinas to New Mexico and Mexico. Georgia, Alabama, and Mississippi soon became the most important producers of grafted pecan nuts, exceeding the total annual production of the states of Texas and Oklahoma, which have the greatest numbers of native seedling trees. Canada has been the principal importer of U.S. pecans.

For good kernel development, even the earliest maturing pecans need high summer temperatures both day and night, so nuts are seldom matured on trees in northern California, northern Indiana, or north of tidewater Virginia and Maryland in the eastern U.S. Results in inland central and southern California have been a little better, but walnuts outyield pecans there. The pecan has been introduced into many countries, but without becoming important

(LEFT) BRANCH OF A PECAN TREE SHOWING NUTS ENCLOSED IN HUSKS. (RIGHT) MATURE PECANS

in production outside the U.S. and northern Mexico. It is cultivated to a limited extent in Australia (New South Wales) and South Africa (Natal).

Pecan varieties are suited, for reasons of climatic requirement, to particular zones within the U.S. Important southeastern varieties are Brooks, Candy, Curtis, Desirable, Elliott, Farley, Mahan, Moore, Stuart, and Success. In the central Texas group are Barton, Burkett, Clark, San Saba Improved, Squirrel, Texhan, and Western. Clarksville, Giles, Greenriver, Hirschi, Major, Peruque, Posey, Starking, and Witte ripen in midwestern orchards. Duvall and Sweeney were introduced from Maryland. For culture somewhat north of pecan limits, there are hicans (pecan-hickory hybrids) of which Burton, Des Moines, Henke, and Jay Underwood are among the fruitful varieties, and McCallister, a useful pollinator.

PECCARY, the New World counterpart of the swine, forming the family Tayassuidae. Peccaries resemble small pigs and are about 2½ to 3 ft. long, with small erect ears and no tails. They are hunted for their hides and for their meat, which is much esteemed. Although ferocious when hunting in packs, they are sometimes tamed by South American Indians and then become practically domesticated.

WILLIS PETERSON

COLLARED PECCARY (TAYASSU TAJACU), NATIVE FROM EXTREME SOUTHWESTERN U.S. TO PARAGUAY

Peccaries differ from true pigs in having only three toes on their hind feet, and upper canine teeth that are directed downward. They possess a scent gland under the skin opening on the ridge of the back; from this derives the old traveler's tale that they have two navels, one above and one below. Peccaries live in herds of 10 to 100 and are not restricted in home range but travel over considerable tracts of territory, undeterred by thick bush, rivers, or other obstacles. They are distributed over nearly all the Americas southward from Texas to Patagonia. They entered the southern continent in comparatively late geological times. Peccaries give a barklike alarm call and when disturbed make a rattling sound by chattering their teeth.

Little is known of their breeding habits. Those of Panama probably breed in June, with a gestation period of 120–125 days. One or two young are produced at birth, very rarely three; the female has only two teats.

There are two species: the collared peccary (*Tayassu tajacu*), dark gray with a white band across the chest from shoulder to shoulder, and the white-lipped peccary (*Tayassu pecari*), slightly larger and darker in colour, with a light area around the mouth. Both species are widely distributed in South America, but the white-lipped peccary does not extend so far to the north or south as the collared peccary. *See* also ARTIODACTYL. (L. H. M.)

PECHENEG, the name of a Turkic people (in Byzantine sources called *Patzinakoi*, in Latin *Bisseni*, in Hungarian *Besenyö*), which between the 6th and the 12th centuries A.D. played an important role in the history of the steppes north of the Black Sea. Their name first occurs in the Arabic work of Ibn Rusta (*c.* 912), who relies on earlier information from Jayhani's lost work. According to the Byzantine emperor Constantine VII Porphyrogenitus, whose *De administrando imperio* is the main source on Pecheneg history, three of the eight tribes constituting the Pecheneg nation were also called Kangar. This name, however, occurs as early as in the 6th century in Syriac sources, where the people that it designates are said to have lived south of the Caucasus.

According to Marvazi, whose work, written *c.* 1120, incorporates much earlier information,

> the Pechenegs are a wandering people, following the rainfalls and the pasturage. Their territory extends a distance of 30 days in either direction, and they are bordered on all sides by many peoples; to the north are the Kipchaks, to the southwest the Khazars, to the east the Oghuz, and to the west the Slavs.

This seems to tally with Constantine, who puts the original seat of the Pechenegs between the rivers Volga and Yaik (now Ural). Around 889 the Pechenegs were driven away from there by a simultaneous attack of the Khazars and the Oghuz. Moving westward, they ousted the Hungarians from the country called Levedia, situated somewhere between the lower Don and the Dnieper. The Hungarians moved farther west, into the so-called Etelköz, where in 896 they were again attacked by the Pechenegs, acting as allies of the Bulgarian tsar Simeon. This Pecheneg victory had a lasting effect on eastern European history: the defeated Hungarians set out to conquer the Carpathian Basin, the country in which they were to stay. Thus in the first half of the 10th century the Pechenegs were in command of the lands between the Don and lower Danube and were constituting a serious menace to the Byzantines.

The military importance of the Pechenegs was such that Constantine Porphyrogenitus considered the maintenance of friendly relations with them to be one of the foremost duties of the em-

peror. This was difficult to achieve, and during the 10th century the Pechenegs repeatedly invaded Thrace. With the Byzantine conquest of Bulgaria the Pechenegs became immediate neighbours of Byzantium, and in the course of the 11th century their raids grew both in frequency and intensity. Constantine IX Monomachus settled some of the Pechenegs on former Bulgarian territory, but these federates were unable and perhaps also reluctant to resist the tremendous pressure of their kinsmen remaining beyond the pale, whose raids led them in the winter of 1090–91 to the very gates of Constantinople. But the Pechenegs' finest hour was almost their last. In his desperate need the emperor Alexius I obtained the aid of the Kumans, and on April 29, 1091, the Pecheneg army was annihilated. Though their last attack on Byzantine territory was in 1122, the defeat of 1091 marks the end of their real power.

The Pechenegs were a menace not only for Byzantium but also for the Russian principalities and Hungary. They were, however, successfully kept at bay by Yaroslav I the Great of Kiev and by László I of Hungary. At a later date, probably after the great reverses suffered at Byzantine and Kuman hands, important Pecheneg settlements were established in Hungary.

(Ds. Sr.)

PECHENGA (formerly the Finnish Petsamo), a town in Murmansk *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands at the head of Pechenga Fjord of the Barents Sea. An ice-free port and the northern terminus of the Arctic Highway from the Gulf of Bothnia, the town had to be ceded to the U.S.S.R. by Finland after the Winter War in 1940. Although reoccupied during World War II by the Finns and Germans, it was recaptured by the Russians in 1944 and its cession was confirmed in 1945. The centre of an important nickel and copper mining area, it has an ore refinery and is the base for a large herring fleet operating in the fjord. (R. A. F.)

PECHORA, a river in the U.S.S.R., is 1,814 km. (1,127 mi.) long and drains an area of 327,000 sq.km. (126,255 sq.mi.). The greater part of its basin lies in the Komi Autonomous Soviet Socialist Republic, U.S.S.R., but the lowest reaches and the delta are in Archangel *oblast*. The Pechora rises at a height of 675 m. (2,214 ft.) in the Ural Mountains, 19 km. (12 mi.) NE of Mt. Koyp. At first a mountain stream flowing south in a narrow, deep valley, the river swings west and north, receiving its tributaries, the Ilych, Shchugor, and Usa (itself more than 677 km. [421 mi.] long). The river and its flood plain both widen steadily. After the Usa confluence the Pechora swings to the southwest and, having joined the Izhma, Pizhma, and Tsilma, turns north once more to its delta on Pechora Bay of the Pechora Sea (the southeastern corner of the Barents Sea). Below the Usa confluence the river varies from 503 to 1,509 m. (550 to 1,650 yd.) in width. Its average annual discharge is 144,800 cu.ft. a second. Almost half the yearly flow occurs in spring, when a maximum of 1,221,900 cusecs. has been recorded. The period during which ice forms is lengthy, but the river is frozen hard by early November. The thaw comes in late April in the upper course and in the first half of May in the lower, thus causing severe ice jams and flooding. Navigation is possible in the open season as far as Ust-Unya for small craft. There is much timber rafting to the sawmills of Naryan-Mar at the head of the delta. In the basin are important mineral deposits: coal in the upper Usa Valley around Vorkuta, petroleum and natural gas near Pechora town and Ukhta. (R. A. F.)

PECKHAM, RUFUS WHEELER (1838–1909), associate justice of the United States Supreme Court from 1896 to 1909, is chiefly remembered as the author of the majority opinion (*Lochner v. New York*, 198 U.S. 45 [1905]) which evoked one of the sharpest dissents by Justice Oliver Wendell Holmes (*q.v.*). Peckham held that the 14th Amendment prevented the states from curtailing a man's liberty to engage in or contract concerning economic activity—in the Lochner case, the liberty of a baker to contract for working hours longer than ten per day. Holmes replied in dissent that the "Fourteenth Amendment did not enact Mr. Herbert Spencer's *Social Statics*." Peckham is representative of the school of constitutional jurisprudence that felt it was the court's function to scrutinize carefully and form its own conclusion as to the reasonableness of a state regulation (*see* Supreme Court of the United States, The: *Role in American Life: Self-Limitation*). This judicial approach in cases involving economic regulation did not disappear until the 1930s, when the Holmes point of view became the almost unanimous opinion and such legislation as the minimum-wage law was held to be constitutional.

Peckham, a member of a distinguished New York judicial and legal family, was born in Albany, N.Y., on Nov. 8, 1838, and was educated in Albany and Philadelphia. In 1859 he was admitted to the bar and began practising law in Albany; in 1883 he was appointed a justice of the New York State Supreme Court and in 1886 became a member of the Court of Appeals of New York, the highest court in the state. Nominated to the U.S. Supreme Court by Pres. Grover Cleveland after the nomination of his brother, Wheeler Hazard Peckham, failed of Senate confirmation, he took office on Jan. 6, 1896. Peckham died at Altamont, near Albany, on Oct. 24, 1909. (A. Dm.)

PECOCK, REGINALD (d. *c.* 1460), bishop of St. Asaph and then of Chichester, a polemicist against the Lollards who was himself convicted of heresy, was born between 1390 and 1395, probably in Wales. A fellow of Oriel College, Oxford, he was ordained priest in 1421 and became rector of St. Michael Royal and master of Whittington College in London in 1431; he soon began to preach and to write against the Lollards. Consecrated bishop of St. Asaph in 1444, his translation to Chichester early in 1450 seems to have been due to the favour of William de la Pole, duke of Suffolk, and further strengthened Pecock's connection with the doomed house of Lancaster.

In attacking the Lollards, Pecock himself advanced some heterodox views, and these gave his political enemies of the Yorkist faction an excuse to proceed against him. Thomas Bourchier, archbishop of Canterbury, was persuaded to order an examination of his books and at a trial on Nov. 28, 1457, Pecock was offered the choice of abjuration or burning; he publicly recanted at St. Paul's Cross on Dec. 4. His subsequent appeal to Rome was favourably received by Pope Calixtus III; but Calixtus died in August 1458, and his successor, Pius II, gave ear to Pecock's enemies. Pecock was confined to Thorney Abbey, Cambridgeshire, where he was to have "no books to look on . . . nothing to write with; no stuff to write upon." He died there in about 1460–61.

Pecock wrote in English, attempting to present philosophical and theological argument in terms that could be grasped by laymen. He had an immense faith in the authority of reason and the power of syllogistic argument. His chief work, the *Repressor of Overmuch Blaming of the Clergy*, issued about 1455, has an exceptional interest for the striking style of the English in which it is written, which fittingly matches the strength of the thought.

Bibliography.—For Pecock's works, see *The Repressor of Overmuch Blaming of the Clergy*, ed. by C. Babington (1860); *The Book of Faith*, ed. by J. L. Morison (1909); *The Reule of Chrysten Religioun*, ed. by W. C. Greet (1927), *The Donet* and *The Folewer to the Donet*, ed. by E. V. Hitchcock (1921, 1924), all for the Early English Text Society. *See* also V. H. H. Green, *Bishop Reginald Pecock* (1945).

PECOS, a river in the southwestern United States, rises in Mora county in north-central New Mexico in the high peaks of the Sangre de Cristo Range. It is about 735 mi. (1,183 km.) long and drains about 38,300 sq.mi. (99,197 sq.km.) of wild and rugged land which in places is devoid of population and communications. The Pecos flows south-southeast through eastern New Mexico and west Texas, emptying into the Rio Grande as it leaves Pecos canyon 40 mi. (64 km.) N.W. of Del Rio, Tex. After leaving the mountains, the Pecos flows over land of desert character and the stream channel is dry much of the year. A valley 1,000 ft. (305 m.) deep and from 5 to 30 mi. (8 to 48 km.) wide extends almost to Roswell, N.M.

Near Roswell, the river widens into a basin which closes somewhat to a broad, shallow valley at the Texas-New Mexico border. Below this valley and in the last 125 mi. (201 km.) of its course, the Pecos has cut a narrow canyon over 1,000 ft. deep into the

Edwards and Stockton plateaus. As the stream emerges from this canyon it empties into the Rio Grande. Flow of the Pecos is regulated by two reservoirs. The Alamogordo at Fort Sumner, with storage capacity of 122,100 ac.ft., was completed in 1938. McMillan dam near Lakewood, N.M., stores 38,660 ac.ft. and was completed in 1906. About 150,000 ac. are irrigated from these units. Pecos tributaries include the Hondo, Gallinas, Felix, and Black rivers, all in New Mexico. Santa Rosa, Fort Sumner, Roswell, and Carlsbad, N.M., and Pecos, Tex., are important towns on or near the river. (M. J. L.)

PÉCS (Ger. FÜNFKIRCHEN), one of the oldest and most interesting towns of Hungary and capital of Baranya *megye* (county), lies on the southern edge of the Mecsek Mountains, about 137 mi. (220 km.) SSW of Budapest by rail. Pop. (1960) 114,713. The earliest occupation of this site was by the Illyrians and by the Celtic tribes known as Pannonians. The Romans had a settlement there called Sopianae. In the early Middle Ages the town became known as Quinque Ecclesiae ("five churches"), and in 1009 Stephen I made it a bishopric. The town has a well-marked rectangular core of medieval origin surrounded by suburbs. The Romanesque cathedral dates from the 11th century although it was much restored in 1881–91. The Turks held Pécs from 1543 to 1686; traces of their rule remain; *e.g.*, in the parish and "hospital" churches, once mosques. The 14th-century university, the earliest in Hungary, perished with the Turkish conquest, but was newly founded in 1922. In the 18th century German colonists entered the city and German miners came to work the coal seams. The rapid rise of population in the 20th century (10,000 in 1920) was mainly due, however, to a big intake of Hungarian peasants. The economic importance of Pécs comes from the proximity of the biggest and richest coal mines in Hungary. Local industries include the making of leather goods and majolica, and the surrounding vineyards are some of the best in Hungary. The town has good rail and road connections. (H. G. S.)

PECTIN, the commercially concentrated extract of a group of pectic substances found in the cell walls and intercellular layers of certain plant tissues. Chief use of commercial pectin is in the preparation of jellies, jams, and marmalades but its property of forming thick solutions gives it numerous uses in the food, confectionery, pharmaceutical, and textile industries.

Pectic substances consist of an associated group of three polysaccharides: an araban, which on acid hydrolysis yields L-arabinose; a galactan, giving D-galactose on hydrolysis; and, most significantly for the physical properties of these substances, a pectic acid whose carboxyl groups are in part esterified with methanol and in part neutralized as salts of calcium and magnesium. Pectic acid is a polysaccharide in which units of D-galacturonic acid are joined in α-D-(1 → 4) linkages (*see* CARBOHYDRATES). The calcium salt of pectic acid is water insoluble and in the maturation of tissues, as in the ripening of fruits, complex enzymic changes occur in which the calcium salts are converted, in part, to methyl ester groups. The pectic substances are extractable with warm aqueous solutions of dilute acids. The extract may then be concentrated and sold as a liquid or converted to a powder. The product is known as pectin. The chief sources of commercial pectin are citrus waste and apple pomace. Sugar beet cossette (chip) pulp is employable and makes a usable product after suitable modification to remove an acetate ester group present.

Pectin forms a viscous aqueous solution and in the presence of acids, such as those of fruits, and added sugar, this solution will produce a jelly. Very small amounts (less than 1%) of pectin will suffice. It has been found that if the methyl ester (methoxyl) content is decreased, less sugar is required to give a gel which is formed by the addition of calcium ions.

PEDERSEN, CHRISTIERN (*c.* 1480–1554), Danish humanist, one of the first to rediscover Denmark's national literary and historical heritage and to encourage the development of a vernacular style. Born near Helsinki (Helsingfors), he studied at Greifswald and took orders in 1505. In 1508 he went to Paris and there produced the first edition (now lost) of Saxo Grammaticus' *Gesta Danorum*, under the title *Historia danica* (1514). He also edited Peder Laale's proverbs and published a Latin-Danish lexicon. Returning to Denmark, he supported the Reformation and became secretary to Christian II, following him into exile in 1525. In Holland he translated, from the Vulgate, part of the New Testament (1529) and the Psalms (1531) and also adapted some of Luther's tracts. In 1532 he set up as a printer at Malmö, publishing Danish versions of French romances and the legends of Charlemagne. He had a share in the translation of the Bible published in 1550 as "Christian III's Bible," and based on Luther's translation, which marked an important stage in the development of Danish literature as well as in the progress of the Reformation. He died on Jan. 16, 1554, in Helsinge.

See Pedersen's *Danske Skrifter*, ed. by C. J. Brandt and B. T. Fenger, 5 vol. (1850–56).

PEDERSEN, HOLGER (1867–1953), Danish linguist of exceptional competence in a number of fields, especially Celtic, was born at Gjelballe, near Lunderskov, on April 7, 1867. After receiving his doctorate in 1897 with a masterly dissertation (*Aspirationen i Irsk*) he proceeded, while professor at Copenhagen, to enrich linguistic scholarship with an incredible number of articles and books, all highly original. Nurtured in the exacting methodology of the 19th century neogrammarian (*q.v.*) movement, he went far beyond its limits and was either participant in, or critic of, most succeeding schools of linguistic thought; he even anticipated some new trends, but conscientiously avoided frills and fads.

The results of Pedersen's Celtic researches are contained in numerous articles and in his monumental *Vergleichende Grammatik der keltischen Sprachen*, (2 vol., 1909–13), also his *Concise Comparative Celtic Grammar* (with Henry Lewis, 1937). About 30 books in four languages (Danish, English, French, German) treat authoritatively Albanian, Armenian, Russian, Indo-European dialects, Lithuanian, Hittite, Tocharian, Czech, Turkish phonology, the relations between Indo-European and Semitic, between Indo-European and Finno-Ugric, the origin of runes, and the history of linguistic science. Holder of honorary degrees in nine countries and recipient of countless other scholarly honours, Pedersen closed a long and fruitful career in Copenhagen, where he died on Oct. 25, 1953. (R. A. Fs.)

PEDERSEN, JOHANNES PEDER EJLER (1883–), Danish Old Testament scholar and Semitic philologist, important for his conception of Israelite culture and modes of thought based on religio-historical and sociological studies, was born on Nov. 7, 1883, at Illebolle on the island of Langeland. He matriculated at the University of Copenhagen in 1902 as a student of divinity. The Old Testament in particular aroused his interest, and he studied Semitic languages under Frants Buhl. A graduate in divinity (1908), he went abroad for three years, studying under Heinrich Zimmern, August Fischer, Christiaan Snouck Hurgronje, and Ignaz Goldziher. He was appointed docent in Old Testament exegesis at Copenhagen (1916–22) and then professor of Semitic philology (1922–50) in succession to Buhl. His doctoral thesis (1912) showed him to be an eminent philologist with an exceptional ability to enter into the spirit of the ancient Oriental trains of thought.

These qualities are even more pronounced in his chief work, *Israel: Its Life and Culture*, in four volumes (1920–34; Eng. trans. 1926–40). These studies of ancient Israel marked a new departure in Scandinavian Old Testament research. Pedersen's conception of the importance of the cult led in many aspects to a break with Julius Wellhausen and his school, especially in his estimation of the narratives and the laws in the Pentateuch as sources for the history of Israel. (E. HB.)

PEDIATRICS: *see* CHILDREN, DISEASES OF; INFANTS, CARE OF.

PEDIMENT, in architecture, is a triangular gable end treated in classical style and crowned with a raking cornice; or a similar

form used decoratively. The pediment was the crowning feature of the Greek temple front, the entablature over the columns being carried completely through, horizontally under the pediment, and the tympanum or triangular wall surface between this horizontal cornice and the raking cornice above being often decorated with sculpture. (*See* GREEK ARCHITECTURE and, for pedimental sculpture, GREEK ART.) The Romans further adopted the pediment as a purely decorative form to crown doors, windows, and especially niches, and frequently made pediments occurring in a row alternately triangular and segmental in shape; this was copied in the High Renaissance in Italy.

Following certain late Roman precedents, in which the line of the raking cornice is broken back in the centre, the designers of the Baroque period developed all sorts of fantastic broken, scrolled, and reverse curved pediments; in some cases they even reversed the direction, so that the high part of the broken or sectional pediment was toward the outside of the composition rather than toward the centre, and in the Churrigueresque, or late Renaissance of Spain, little sections of pediment were used to indicate line patterning.

PEDIMENT, in geology, a low-angle slope of ½°–7°, and of slightly concave form, found at the base of hills in regions where the rainfall comes in heavy storms. There is frequently a sharp break of slope between the pediment and the steeper hillside above it. There may or may not be a soil cover. Water passes across the pediment by laminar sheet flow, but if this is disturbed the flow becomes turbulent and gullies develop. Many tropical towns sited on pediments (which offer easier building sites than the steep hillsides above or the river marshes below) show severe gullying where the water flow has been concentrated between walls and buildings.

The pediment is the most important element in the tropical landscape, both for building and farming; under natural conditions it is the most permanent part of the landscape, but it is also the part most easily destroyed by human interference.

(J. C. PH.)

PEDODONTICS is the practice of dentistry for children; it is the dental counterpart to pediatrics in medicine. Seven qualifications for a pedodontist have been listed by the American Board of Pedodontics: the pedodontist should be able to manage the behaviour of a very young patient and control his relations with the child's parent; he should be a master of the operative and restorative procedures that are practised for the deciduous (first) teeth and the immature permanent teeth; he should possess a thorough knowledge of the physical and chemical properties of the materials employed in all types of dental treatment and utilize them with skill; he should be able to remove children's teeth skillfully and perform the minor oral surgery that may be required; he should be able to provide root canal treatment for infected teeth and confirm bacteriologically the removal of infecting microorganisms; he should be able to diagnose and treat any juvenile dental problem of growth, development, or health; and he should be able to instruct the family in proper dental health practices and to institute measures for the prevention of defects of the teeth or the mouth.

During the years when dentistry was developing from a mechanical trade, learned by apprenticeship, to a health profession, the teeth of young children were neglected consistently. The "baby" teeth, it was thought, would be replaced promptly by the adult or permanent teeth, hence the first set of teeth was unworthy of the expenditure of the dentist's time and the family's resources. From 1840, when the first dental school in the world was established in Baltimore, Md., until 1916, when teaching in dental schools in the United States was reorganized to include the human biologic sciences, children's teeth generally were treated by removal whenever they ached. The teaching of scientific techniques in dental schools for the comprehensive treatment of the teeth and mouths of children came even later.

On the child's first visit, which should take place when the child is 2½ to 3 years old, many pedodontists introduce the child to the equipment and instruments of the dental office; secure a sample of saliva to be used in obtaining a count of acid-producing microorganisms; complete the cleansing and polishing of the teeth, much as in an adult's dental prophylaxis; and instruct the child in proper toothbrushing. In those geographical regions in which the water supply is deficient in fluorine, a series of applications of a fluoride solution to the dried surfaces of the teeth sometimes is instituted. Such a series, begun at three years of age, has been shown to cause a 40% reduction in the number of cavities. A comprehensive examination, including dental X-rays and a check of the child's occlusion (bite), also may be made during the initial visit.

At a later visit, for the benefit of the child whose salivary examination indicates the presence of a large number of lactobacilli, the entire family may be placed on a diet low in sugar for a few weeks to change the bacterial flora of the mouth. The process of dental caries generally can be halted by periodic dietary restrictions of this type.

See also DENTISTRY; ORTHODONTICS. (KH. A. E.)

PEDRARIAS DÁVILA: *see* ARIAS DE ÁVILA, PEDRO.

PEDRELL, FELIPE (1841–1922), Spanish composer and musical scholar who devoted his life to the development of a Spanish school of music founded on its national folk songs and its own great musical heritage from the past, was born at Tortosa, Feb. 19, 1841. As a choirboy his imagination was first fired by contact with early Spanish church music. Though largely self-taught he composed several operas, mostly on national subjects. The first, *El último Abencerraje*, founded on a text by Chateaubriand, was produced in an Italian version in Barcelona in 1874. In 1891 he published his manifesto *Por nuestra musica*, which attracted much attention, though it was misunderstood as advocating Wagnerian reforms. Following his theories, he set a practical example by publishing an invaluable four-volume collection of folk songs and editing, for the first time, a vast quantity of early Spanish church, stage, and organ music, including the keyboard works of Antonio de Cabezón and the complete works of Tomás Luis de Victoria. At the same time he was working on an operatic trilogy, the first part of which, *Els Pirineus* (to a Catalan libretto), was produced in an Italian version in 1902. The second part, *La Celestina*, though it contained some of his finest music, remained unperformed. He died at Barcelona on Aug. 19, 1922. As a composer Pedrell was, to a certain extent, hampered by technical shortcomings. His influence on later Spanish composers, however, particularly through his pupil Manuel de Falla, was incalculable, and his editions of early Spanish music laid the foundations of Spanish musicology. (L. SA.)

PEDRO I (1798–1834), founder of the Brazilian empire and first emperor of Brazil, 1822–1831. Pedro was born in Lisbon, Port., on Oct. 12, 1798, the son of King John VI of Portugal. When the French conquered Portugal in 1807, Pedro accompanied the royal family in its flight to Brazil. He remained there as regent when King John returned to Portugal at the behest of parliament in 1821. According to legend, King John, aware of the mounting sentiment for separation from Portugal, advised Pedro to assume leadership of the independence movement, if necessary, so that Brazil and Portugal might remain united under the Braganza dynasty. Pedro surrounded himself with ministers who counseled independence. When the Portuguese parliament demanded that he return to Lisbon "to complete his political education," he refused; when it sought to curb his authority, he declared Brazil independent in the *grito do Ipiranga* (*q.v.*) on Sept. 7, 1822. Brazil was established as an empire with Pedro as its first ruler. However, his initial popularity soon waned in the face of widespread resentment against the Portuguese nobility that influenced his court. In the constituent assembly of 1823 an attempt was made to draft a liberal constitution reducing the emperor's powers and curtailing the rights of the Portuguese in Brazil. Pedro dissolved the assembly and exiled its leaders. In 1824 he issued the basic charter that governed Brazil for the next 65 years. Pedro's autocratic manner, his continued interest in Portuguese affairs, and the failure of his military forces to uphold Brazil's claims to Uruguay combined to alienate his subjects. His reign was marked by a series of local uprisings, some reflecting republican ideals. In 1831 he abdicated in favor of his son, Pedro II, then five years

old, and returned to Portugal. He died in Lisbon on Sept. 24, 1834, fighting to secure his daughter's rights to the Portuguese throne. (R. E. P.)

PEDRO II (Dom Pedro de Alcántara) (1825–1891), second and last emperor of Brazil, was born in Rio de Janeiro on Dec. 2, 1825, and died an exile in Europe in 1891. On April 7, 1831, when he was as yet not six years old, his father, Pedro I, abdicated in his favour, and for nine years Brazil was governed by a regency. Statesmen declared Pedro of age in July 1840 and crowned him emperor on July 18, 1841. Disturbances in the provinces, which had plagued the regency, continued for the next five years; however, by that time the young emperor's intellectual curiosity and profound concern for his subjects were recognized by his subjects and a vast majority of them gave him almost unqualified support for the next 40 years. He considered himself the arbiter of Brazil's political life, and he used the "moderative power" given him by the constitution to regulate the antagonistic groups that sought to dominate the country. Pedro is supposed to have said, "Were I not a monarch I should be a Republican." A president of Argentina called his rule a "crowned Democracy." When a dictator-president of Venezuela learned of Pedro's overthrow in 1889, he exclaimed, "The only Republic in South America is ended—the Empire of Brazil." It is true nonetheless that Pedro ruled in the interests of a narrow social and economic elite.

The slave trade and slavery, both of which were officially sanctioned in Brazil, had caused seriously strained relations between Brazil and Great Britain before Pedro established his leadership of the country. Once in control, he gave his full support to ending the African slave trade, achieved in 1850, and to the abolition of slavery, ratified in 1888. Approximately 700,000 slaves were freed and no provision was made for compensation to the owners. Pedro strongly insisted upon the government's power to regulate the Roman Catholic Church, but that institution was not submitted to the bitter attacks it experienced in most of the Spanish-American republics.

Pedro was an ardent believer in commercial expansion and technological progress. He supported the founding of banks, and extended special privileges to would-be industrialists. Under his guidance Brazil made significant gains in railroad, telegraph, and cable construction.

The monarch's interest in language, religion, education, and science encouraged him to travel abroad. He made trips to Europe in 1871, 1876, and 1887, and to the United States, in 1876, where he attended the Centennial Exposition.

Pedro's government intervened in Uruguay and in 1852 Brazil's troops were instrumental in the defeat of the Argentine dictator Juan Manuel de Rosas (*q.v.*). Brazilian forces joined with those of Argentina and Uruguay to defeat the Paraguayan dictator Francisco Solano Lopez in the Paraguayan War (1864–70).

Illness prevented Pedro from giving adequate attention to the dissension that arose over the slavery issue and, on Nov. 16, 1889, he was forced to abdicate by military leaders who were convinced that monarchy was an anachronism in the New World. The royal family went into exile in Europe where Pedro died, Dec. 5, 1891. His remains and those of his wife were returned to Brazil in 1920 and placed in a chapel in the city of Petropolis, named in his honour.

See Mary W. Williams, *Dom Pedro the Magnanimous, Second Emperor of Brazil* (1937). (J. J. J.)

PEDRO, kings of Aragon: *see* Peter, kings of Aragon.

PEDRO the Cruel (1334–1369), king of Castile from 1350 to 1369, was born at Burgos on Aug. 30, 1334, the son of King Alfonso XI. Though the contemporary English poet Chaucer praised him, a stronger historical tradition, working from narratives written by his enemies, has, without enquiring into motives, depicted him as a monster of cruelty. Pedro was, in fact, a courageous, energetic, conventionally pious man and a competent general. He was also passionate, entirely uninterested in the chivalric doctrines of his age, impatient of political maneuvering, and overready to kill high-ranking traitors—or merely suspected traitors—without trial. Two forces determined the pattern of his reign. Abroad, John II of France thought the accession of a 15-year-old king provided a long-awaited chance to force Castile into a military alliance against England. The alliance was concluded (1352) and Pedro was forced to marry (1353) Blanche, daughter of Pierre, duc de Bourbon, though he was already passionately in love with the beautiful María de Padilla—who was to remain his mistress, and perhaps his legal wife, until her death (1361). He abandoned Blanche immediately after the marriage. This act ruptured the Franco-Castilian alliance.

At home Pedro was at once confronted by a row of bastard half brothers, led by Henry of Trastamara (later Henry II), who, to win support for his undefined ambitions, proclaimed himself defender of the magnates' privileges against the growing power of the crown. After leading several revolts which Pedro crushed with energy, Henry, who failed to win any popular sympathy, escaped to France (1356) and offered to serve the French crown against his brother. From 1356 to 1366 Pedro was engaged in a bitter war with Aragon, whose king, Peter IV, supported Henry's cause and had ambitions to seize Murcia and eastern Castile. Pedro, for his part, had territorial ambitions in western Aragon. Hostilities had been provoked by an Aragonese admiral acting, apparently, on French orders. During the war Pedro won many successes against Aragon while Trastamaran propaganda failed to undermine Castilian loyalty toward him. In 1365, therefore, the French king Charles V, Pope Urban V, and Peter IV—to save Aragon from being overrun—paid the veteran French mercenaries, the *compagnies,* led by Bertrand du Guesclin, to go to Spain and overthrow Pedro, replacing him by Henry. This was done. Pedro fled to Gascony and requested English help under the Anglo-Castilian alliance, concluded on June 22, 1362. The Trastamarans and their French allies were routed at Nájera (April 3, 1367) by Edward the Black Prince, and Pedro resumed his reign without significant opposition.

After the victory, however, the prince showed complete misunderstanding of the political situation in Castile and—having quarreled with Pedro about finance and chivalry—retired to Gascony, where he pondered plans for making himself king of Castile. Charles V sent Henry back to Spain with more French troops and a long civil war ensued. Eventually Pedro was defeated at Montiel and assassinated there by his brother's own hand (March 23, 1369), though strong loyalist resistance continued for several years. It is clear that Pedro's overthrow was brought about almost entirely by French military intervention and, in its final stages, by the Black Prince's political incompetence.

See P. E. Russell, *The English Intervention in Spain and Portugal in the Time of Edward III and Richard II* (1955). (P. E. R.)

PEDRO, the name of five kings of Portugal.

Pedro I (1320–1367), king from 1357, was born at Coimbra on April 8, 1320, the son of Afonso IV of Portugal and his consort Beatriz of Castile. He was married in 1336 to Constanza, daughter of Don Juan Manuel (*q.v.*); but she died in 1345, and Pedro is chiefly remembered for his tragic amour with Inês de Castro (*q.v.*), whose death he savagely avenged after his accession to the throne. Even so, some of his acts, designed to curb abuses and to enhance the royal power, were of great importance: he reformed the administration of justice (1361) and did much to make the Portuguese Church a national one by insisting on the *beneplácito régio,* that is, the royal approbation of all papal bulls or letters before they could be published in the kingdom. Though before he became king of Portugal he had advanced a claim to the Castilian throne (1354), he later helped Castile against Aragon (1358 and 1360). From 1363, however, he pursued a neutral policy. He died on Jan. 18, 1367, leaving his throne to his son Ferdinand I. (V. R. R.)

Pedro II (1648–1706), king from 1683, was born in Lisbon on April 26, 1648, a son of John IV of Portugal. In November 1667, when his elder brother, Afonso VI (*q.v.*), was sent into lifelong captivity, Pedro became regent of Portugal; and in April 1668 he married his brother's former consort, Marie Françoise Élisabeth de Savoie-Nemours (d. 1683). His first international act was to make peace with Spain (Feb. 13, 1668), forgoing the advantages which might have been expected from Afonso's victories of 1663–65. When Afonso died (Sept. 12, 1683), Pedro became king.

Pedro II's reign was marked by a consolidation of royal absolutism: the *Cortes* never met. For Portugal's commerce, however, Pedro in December 1703 obtained the valuable Methuen Treaty, whereby England reduced customs duties on Portuguese wines in return for Portugal's favourable treatment of English woolen goods. This treaty was largely a consequence of Pedro's having finally adhered (May 1703) to the Anglo-Austrian side in the War of the Spanish Succession, though in June 1701 he had allied himself with France. A Franco-Spanish invasion of Portugal was repelled (1704), and Portuguese troops invaded Spain, but their capture of Madrid (July 1706) was a fruitless victory. Pedro II died on Dec. 9, 1706, leaving his throne to John V, his son by his second wife, Maria Elizabeth of Palatinate-Neuburg, whom he had married in 1687.

PEDRO III (1717–1786), king-consort from 1777, was born in Lisbon on July 5, 1717, the younger son of John V of Portugal. He was married in July 1760 to the daughter of his elder brother, King Joseph I. When she became queen as Maria I (February 1777), Pedro became nominally king. He devoted himself entirely to religious practices. He died on May 25, 1786.

For PEDRO IV of Portugal, *see* PEDRO I, emperor of Brazil.

PEDRO V (1837–1861), king from 1853, was born in Lisbon on Sept. 16, 1837, the eldest son of Queen Maria II. Succeeding his mother on Nov. 15, 1853, he had his father, Ferdinand of Saxe-Coburg, as regent for him till he came of age to rule on his 18th birthday. Meanwhile he went on a long tour of the more progressive states of Europe; in England he formed a close understanding with the prince-consort Albert (his father's first cousin), with whom he later maintained a regular correspondence.

Earnest and enlightened, Pedro V devoted himself to his country's problems. In external affairs, he was concerned with the occupation of Cabinda, Molembo, and Ambriz, in northern Angola (1855); with the final abolition of slavery (1856); with the convention (1857) whereby the Holy See restored the effect of the Portuguese patronate over dioceses in India and the Far East, after having practically abolished it in 1838; and with the detention of the French slave-ship "Charles et Georges" off the coast of Mozambique (1857), which led to conflict with the French government (1858–59). In Portugal itself he had to face successive epidemics of cholera and yellow fever (1854–57). He founded the Curso Superior de Letras (1859) for teaching literature, philosophy, and history at university level.

Pedro V married Stephanie of Hohenzollern-Sigmaringen in 1858, but she died in 1859. Pedro died childless on Nov. 11, 1861. (DA. A. P.)

PEEBLES (TWEEDDALE), an inland county of southern Scotland (area 347.3 sq.mi.), forms an eastward-pointing triangle between the counties of Midlothian, Selkirk, Dumfries, and Lanark.

Physical Features.—The county occupies the upper third of the Tweed Basin, with a northerly extension which includes the southern end of the Pentland Hills. There, lavas and sandstones of Old Red Sandstone Age form broad moorlands at about 1,700 ft., clothed in matgrass, heather, and an association of sheep's fescue and purple moor grass. The moorlands are drained southward by the Lyne Water, whose valley opens out into a basin at 700 ft. around West Linton, before crossing the geological boundary of the Southern Uplands fault into a gorge cut into swelling hills of Silurian rocks. These, cut by the steep-sided, flat-floored valleys of the Tweed itself and its tributaries, the Manor, Leithen, and Eddleston waters, comprise the bulk of the county. South of the Tweed are large stretches of high plateau matgrass moorland at 1,800–2,000 ft., swelling to 2,754 ft. in Broad Law, which are given over to hill sheep farming.

The inland position of the county and its altitude give a severe climate—West Linton, with a January temperature of 0° C (32° F) and a July temperature of 13° C (55° F), averages 40 snowy mornings a year; rainfall exceeds 60 in. in the southwest, 35–45 in. elsewhere, with a winter maximum and a dry spring.

There are several Forestry Commission plantations on the edges of the high plateau; the two largest are Glenbreck (6,517 ac.) and Elibank and Traquair (5,594 ac.), the latter crossing into Selkirk county.

History.—Occupation in the Early Iron Age is indicated by the remains of numerous hill forts around the burgh of Peebles, and there are standing stones near the confluence of Lyne Water and the Tweed. The Romans left traces of their military rule in the camp at Lyne, locally known as Randal's Walls. In medieval times a series of peel towers were erected; the best preserved is that of Neidpath Castle, a 15th-century stronghold of the Frasers just outside the royal burgh of Peebles.

The county is closely associated with the legend of Merlin (*q.v.*) and has provided background and other material for Sir Walter Scott, James Hogg, John Buchan, and other writers. The royal burgh of Peebles (*q.v.*) has interesting links with Mungo Park (*q.v.*) and the Chambers brothers (*see* CHAMBERS, ROBERT). The rebuilt cottage of the Black Dwarf (David Ritchie) lies southwest of Peebles, and Scott's novel *St. Ronan's Well* is generally thought to have been inspired by the mineral springs at Innerleithen (*q.v.*). Other places of historical interest include Traquair House, one of the oldest inhabited Scottish mansions, where William the Lion lived and held court in 1209 and where Mary, queen of Scots, and Lord Darnley stayed in 1566; St. Gordian's Cross at Manor; Cross Kirk, dating from 1261, at Peebles burgh; Drochil Castle, left unfinished by the regent Morton when he was executed in 1581 (*see* MORTON, JAMES DOUGLAS, 4th earl of); and Stobo Kirk, dating from Norman times.

Population and Administration.—The population in 1961 was 14,156, showing a decrease of 7% since 1951. The royal burgh of Peebles (pop. [1961] 5,548), and the burgh of Innerleithen (2,299), also show decreases. The county is combined with Roxburgh and Selkirk to form a joint constituency, returning one member to Parliament. It forms a sheriffdom with the Lothians; there is a sheriff-substitute at Peebles.

The Economy.—Less than one-fifth of the total area is improved land and of this more than a third is under permanent grass; oats occupy half the cropped area, with turnips and rape also important. Cultivation is confined largely to loams of glacial origin bordering the gravel and alluvium of the "haughs," or flat valley floors, which are mainly under grass except where drainage and flood protection make them valuable crop land. Livestock farming predominates, with black-faced sheep on the hills and Cheviot sheep and beef cattle along with the arable on the lower land. High quality tweeds and knitwear are made in Peebles, Innerleithen, and Walkerburn.

The scenery is a valuable asset which has led to increased tourism. There is good trout and salmon fishing in the Tweed and easy access to the hills.

See J. W. Buchan and Rev. Henry Paton (eds.), *A History of Peeblesshire*, 3 vol. (1925–27); Land Utilisation Survey of Britain, *The Land of Britain, Peebles and Selkirk* by D. L. Linton and C. P. Snodgrass (1946); *Third Statistical Account of Scotland for the Counties of Peebles and Selkirk* (1964). (W. GE.; A. T. A. L.)

PEEBLES, a royal and small burgh and the county town of Peebles, Scot., at the junction of Eddleston water with the Tweed, 23 mi. S. of Edinburgh by road. Pop. (1961) 5,548. The burgh consists of the new town, on the south of the Eddleston, and the old on the north. Portions of the town walls still exist, and there are cellars constructed in the 16th and 17th centuries as hiding places against border freebooters. The old market cross stands in High street. The Chambers institution incorporates the mansion where the notorious "Degenerate Douglas," or "Old Q." 4th duke of Queensberry (1724–1810), was born. Of St. Andrew's church, founded in 1195, nothing remains but the tower, restored by William Chambers, the publisher, who was buried beside it in 1883. Cross kirk was erected by Alexander III. in 1261, to contain a supposed remnant of the true cross discovered there. The building remained till 1784, when it was nearly demolished to provide stones for a new parish church. Peebles was a favourite residence of the Scots kings when they went to hunt in Ettrick forest. It was created a royal burgh in 1367 and was the scene of the poem of *Peblis to the Play*, ascribed to James I of Scotland. Peebles lost its importance after the union of the crowns. There are several large woollen mills, and the town is an agricultural centre. The Buchan family (Lord Tweedsmuir) is associated with Peebles, and Mungo Park practised medicine there (1801–03). In June

the "Beltane queen" is crowned, this being a survival of the ancient religion.

On the north bank of the Tweed stands Neidpath castle, of which the ancient peel tower dates probably from the 13th century. Its first owners were Tweeddale Frasers, from whom it passed to the earls of Tweeddale. It was besieged and taken by Cromwell in 1650. The 3rd earl of Tweeddale (1645–1713) sold it to the duke of Queensberry in 1686. The earl of Wemyss succeeded to the Neidpath property in 1810.

PEE DEE-YADKIN, a river system originating as the Yadkin River in northwestern North Carolina, U.S., on the southeastern slopes of the Blue Ridge Mountains. The Yadkin flows northeastward past Wilkesboro and Elkin, N.C., and then turns south. After 202 mi. it joins the Uharie River and continues southward into South Carolina. The combined stream is known thence to the Atlantic as the Pee Dee River. The Pee Dee is named for the eastern Siouan Pedee Indian tribe, which resided along its course in southern North Carolina when that area was first settled. The Pee Dee-Yadkin flows through coastal plain and piedmont areas where it is hemmed in by fairly high hills that serve well in the erection of dams. There are several artificial lakes along the Yadkin. High Rock Lake, formed by a hydroelectric dam, furnishes power for aluminum production at Badin, N.C. Several early settlements on the central North Carolina Piedmont were founded by pioneers who poled boats up the stream. The river is navigable 91 mi. (146 km.) inland from Georgetown, S.C., on the Atlantic, where the Pee Dee meets the Waccamaw, Sampit, and Black rivers. Former rice plantations, now devoted to cattle, vegetables, timber, and hunting activities, line its banks for a score of miles inland from Georgetown.

(M. C. P.)

PEEKSKILL, a city of Westchester county, N.Y., U.S., on the east bank of the Hudson river, 41 mi. (66 km.) above New York City. Peekskill is the shopping centre for northern Westchester and Putnam counties. Its name was derived from that of the adjacent creek, or "kill," on which Jan Peek, an early Dutch settler, conducted an Indian trading post from 1667 to 1677. The village was strategically important during the American Revolution, and large sections of it were burned by the British on March 23, 1777. It became a city in 1940.

For comparative population figures *see* table in NEW YORK: *Population.* (M. H. LE.)

PEEL, SIR ROBERT (1788–1850), British home secretary from 1822 to 1827 and from 1828 to 1830, prime minister from 1834 to 1835 and from 1841 to 1846. The leader of the Conservative Party that emerged after the Reform Act of 1832, a free trade reformer, and the repealer of the Corn Laws in 1846, Peel was one of the outstanding British statesmen and administrators of the 19th century. His policy did much to ease Britain's difficult social and economic transition from an agricultural and mercantile to a primarily industrial society in the 50 years following the close of the Napoleonic Wars in 1815. He was born on Feb. 5, 1788, at Bury in Lancashire. His grandfather was a small yeoman farmer, who became one of the pioneers of the Lancashire cotton industry. His father, Sir Robert Peel, was a shrewd and ambitious businessman who built up a large cotton-manufacturing interest, purchased a landed estate at Drayton, near Tamworth, Staffordshire, entered the House of Commons (1790) and was made a baronet by the younger Pitt in 1800. Robert Peel, his eldest son, was educated at Harrow School (1800–04) and Christ Church, Oxford (1805–09), where he was the first to achieve a double first in classics and mathematics in the new degree examination. With his father's money and government influence a parliamentary seat was found for him as soon as he came of age and in April 1809 he was returned as M.P. for Cashel city, County Tipperary.

BY COURTESY OF THE NATIONAL PORTRAIT GALLERY, LONDON

MARBLE BUST OF SIR ROBERT PEEL BY MATTHEW NOBLE. IN THE NATIONAL PORTRAIT GALLERY, LONDON

Secretary for Ireland (1812–18).—Like his father Peel was from the start a government supporter and received an early appointment as undersecretary for war and the colonies in 1810. Two years later he accepted the difficult post of chief secretary for Ireland. During his six years in this office he made his reputation as an able and incorruptible administrator. With the war on the continent still in a critical phase, he was faced in Ireland with the first serious Catholic agitation since Pitt's Act of Union in 1800. In 1814 he was largely responsible for the suppression of the Catholic board, the semi-illegal central committee of the movement, and thus effectively checked the course of Irish agitation for another nine years. Increasingly, however, he was impressed by the endemic anarchy of Irish society and the economic poverty and disorganization from which it derived. To deal with the problem of crime and disorder he carried through the Peace Preservation Act of 1814, which made possible the formation of a body of national police later known as the Royal Irish Constabulary, popularly called "Peelers." In 1817 came the first serious Irish famine of the century, but Peel's energy and practical sense in raising relief funds and supervising the distribution of food carried the country through the crisis without serious disorder. When Peel's Irish secretaryship ended the following year he was already marked out for early promotion. At the same time, partly because of family tradition and early education, partly because of his role in the House of Commons as spokesman for the Irish government, he had distinguished himself as the ablest of the "Protestant" party which resisted the recurrent efforts to pass Catholic emancipation. This issue, which divided the Cabinet as well as ordinary political parties, was primarily concerned with the admittance of Roman Catholics to membership of Parliament and high offices of state from which they were still legally barred. Peel's brilliant speech in the emancipation debates of 1817 was widely held to be decisive in defeating the proposed measure and was instrumental in securing his election to the coveted honour of member of Parliament for Oxford University later the same year.

In 1820 Peel married Julia, the beautiful younger daughter of Gen. Sir John Floyd, a veteran of the wars in India and second-in-command of the forces in Ireland when Peel first went there. The marriage was ideally successful and for the rest of his life Peel enjoyed a serene family life. Following his marriage Peel built an elegant house in Whitehall Gardens and began the collection of paintings, mainly of the Dutch, Flemish, and contemporary English schools, for which he became famous among art connoisseurs. When on his father's death in 1830 Peel succeeded to the baronetcy and estate, he made his home at Drayton. A magnificent manor house was built on the site of the old, and he administered his estate with zeal and knowledge, developing the property and encouraging scientific methods of drainage, fertilizers, and stock breeding among his tenants.

After his departure from Ireland in 1818 Peel twice declined minor appointments though he remained an active government supporter. In 1819 he was made chairman of the important currency committee which brought about the return of the gold standard. Though expert opinion was generally in favour of ending the wartime system of paper currency, the deflationary policy carried through under the act of 1819 became a major controversial issue. By his subsequent defense of this measure Peel became identified with the gold standard policy to which his opponents attributed much of the industrial and agricultural distress of the 1820s.

Home Secretary (1822–27, 1828–30).—In the reconstruction of 1822 by which the earl of Liverpool endeavoured to strengthen his unpopular ministry, Peel accepted the post of secretary of state for the home department and a seat in the cabinet. His first task was to meet the long-standing demands in Parliament, made

by the Whig legal reformers, Sir Samuel Romilly and Sir James Mackintosh, for a radical change in the criminal laws. In a series of five acts in 1823 Peel carried out most of the reforms suggested by Mackintosh's 1819 committee. He then proceeded to a comprehensive reorganization of the criminal code. Between 1825 and 1830 he effected a fundamental work of consolidation and reform, covering three-quarters of all criminal offenses. Though accompanied by a progressive reduction in the severity of punishment, the main object of Peel's work was to repeal obsolete legislation, simplify judicial procedure, and reduce the mass of old and confused penal laws to a small number of short, intelligible statutes. On the controversial issue of capital punishment he preferred to move more slowly, retaining a wide degree of administrative discretion while waiting to see the effect of his initial measures. The rising statistics of crime convinced him that legal reform should be accompanied by improved methods of crime prevention and detection. In 1829 he carried through the Metropolitan Police Act, which set up the first disciplined police force for the whole London area (excluding the City); its headquarters were at Scotland Yard. The nickname of "Bobby" for its members was a popular tribute to the founder of the force. In the general administration of the country the main task of the home office was to preserve order in the periodic disturbances arising from unemployment and agitation in the industrial districts. Though concerned at the increasing activity of the trade unions, following the removal of the restrictive Combination Acts in 1824–25, Peel observed a policy of nonintervention in industrial disputes and tried to induce both masters and men to conform with the law. He used pressure on local magistrates to see that cotton mills were properly inspected, and by calling for returns on conditions of child labour helped to repair the widespread neglect by magistrates and mill owners. In the bad year of 1826, when there was extensive industrial rioting in the north and west of England, he was able to restore order without recourse to emergency legislation; then, and in the less serious disturbances of 1829, he ensured that relief funds were available to the distressed areas.

Catholic Emancipation.—When George Canning succeeded Liverpool in April 1827, Peel resigned on the issue of Catholic emancipation though in other respects he and Canning both belonged to the more liberal wing of Liverpool's old Cabinet. After Canning's death (August 1827) and the collapse of the Goderich ministry early in 1828, he returned to office under Wellington as home secretary and leader of the House of Commons. He endeavoured to reunite the old Liverpool party by including William Huskisson and other followers of Canning in the new administration; personal and political differences between Huskisson and Wellington led to the resignation of the Huskisson group after four months in office. The secession considerably weakened the government, which had substantially less support in the House of Commons than Liverpool's Cabinet. A Whig motion for the repeal of the Test and Corporation Acts, which debarred Dissenters and Roman Catholics from municipal and public office, was carried against the government in February 1828 and this first successful attack on the supremacy of the Anglican Church was followed by the Catholic crisis of 1828–29. The Irish movement for emancipation had been renewed in 1823 with the formation of the Catholic Association by Daniel O'Connell. Its growing strength, demonstrated in the general election of 1826, culminated two years later in O'Connell's victory at a by-election for County Clare (July 1828). A month earlier, in May 1828, the House of Commons had carried a motion in favour of emancipation. Convinced that further resistance was useless, Peel proffered his resignation and though the simultaneous defection of the Huskissonites made his immediate retirement difficult, he made it clear that it could only be delayed. Meanwhile he urged the prime minister to prepare for a final settlement of the dispute and promised to give it independent support. Faced with considerable royal and episcopal opposition, Wellington finally persuaded Peel in January 1829 to remain in office and introduce the bill as the only means of carrying through the policy on which they both agreed. When the measure was debated Peel argued that while he was not converted to the principle of emancipation, the threatening state of Ireland and the long-standing divisions in Parliament and Cabinet on the issue left the government with no choice but concession. He suffered bitter personal attacks for his sudden change of front. When on conscientious grounds he resigned his seat for Oxford University, he was defeated at the ensuing by-election; many of the ultra-Protestant supporters of the administration were left angry and hostile. In the following session support for the government was weaker than ever and the general election of 1830 consequent on the death of George IV made no fundamental difference to the political situation. Wellington failed to obtain fresh recruits for his Cabinet, and his declaration against parliamentary reform at the opening of the new session in November 1830 brought about the fall of his government.

Parliamentary Reform: First Ministry (November 1834–April 1835): Conservative Leader.—In the reform crisis that followed, Peel's position was difficult and ambiguous. Though not opposed to moderate parliamentary reform, he was shocked by the sweeping measure introduced by Earl Grey's ministry in March 1831, and by their subsequent appeal to the electorate and the forces of public agitation. Convinced that reform could not be prevented, he tried to mitigate its effects and used his influence to stiffen the opposition in the House of Lords as a warning to future radical reformers. The divisions in his party made leadership impossible; he made no effort to conciliate the ultra-Tories; his refusal to join Wellington in office and pass a Tory reform bill in 1832 forced the king back on the Whigs and further weakened Peel's standing with his former followers. Nevertheless, he was already looking to the growth of a more durable conservative opinion in the country, and his studied moderation in the first two sessions of the Reformed Parliament (1833–34) did much to restore his political status. The unexpected dismissal of Viscount Melbourne's ministry in November 1834 and Peel's appointment as prime minister gave him an impossible task; though the immediate dissolution of Parliament enabled him to make in the so-called Tamworth manifesto an important statement of conservative reforming principles. At the general election the Conservative Party, though still in a minority, gained 100 seats and for the first time came under his acknowledged leadership. Peel resigned office in April 1835 when beaten by a combination of Whigs, Radicals, and Irish nationalists. During the next six years, aided by his astute and cautious leadership in the Commons and by the careful electoral organization of his subordinates, the Conservative Party steadily increased in numbers and confidence. The hard-fought election of 1837 that followed the death of William IV brought the two main parties to a position of near equality; though a clash with the youthful and whiggish Queen Victoria over the replacement of some of the ladies of her bedchamber caused Peel to abandon taking office in 1839, he was able to carry a vote of no confidence against the government in June 1841. At the succeeding dissolution the Conservatives for the third time running increased their numbers and on Aug. 30, 1841, Peel took office with a working majority of about 70 in the House of Commons. In its achievements and membership the administration he now formed was one of the most outstanding of the century. It included six past or future prime ministers, four future governors of India, and several able young men, notably W. E. Gladstone, Henry Pelham-Clinton, earl of Lincoln (afterward duke of Newcastle), Edward Cardwell, and Sidney Herbert, who later formed the group of "Peelites" which played a formative role in later Victorian politics.

Peel's Second Ministry (1841–46).—At the outset of his ministry, Peel was faced with war in China, the threat of war in India, strained relations with France and the United States, severe commercial distress at home, Chartist agitation among the working classes, the powerful organization of the Anti-Corn Law League, O'Connell's campaign for the repeal of the union, and a five-year accumulation of budgetary deficits. His policy aimed at peace and better trade relations abroad, a reduction in the cost of living for the working classes, and encouragement to trade and industry by progressive tariff reductions and a more stable financial system. One immediate issue was the Corn Laws. The free trade proposals of the outgoing Whig ministry, though widely held to be an elec-

tion maneuver, had ensured that cheap bread was one of the election cries in 1841. Peel defended protection for agriculture on grounds of expediency but had refrained from any pledges and explicitly reserved his right to formulate policy when in office according to his view of national needs. Early in 1842 he brought forward a new Corn bill which reduced the protective duties by about a half but retained a sliding scale (as against the Whig proposal of a fixed duty of 8*s.* a quarter) designed to eliminate sudden price fluctuations. The 1828 Corn Law had not worked satisfactorily and most leading agriculturalists accepted the new bill as a necessary compromise of opposing interests. During the same session Peel restored the financial position of the government by the reintroduction of the wartime income tax for a period of three years. This enabled him not only to meet a deficit of about £2,500,000 but to make a sweeping reduction of duties on about 750 articles of import, mainly food, raw materials, and semimanufactured goods. In 1844 the Bank Charter Act completed the foundations of the Victorian banking and currency system. Designed primarily to put the currency system on a sound basis, it separated the banking and note issue functions of the Bank of England; related the volume of note issue to the amount of bullion reserves; and provided for the gradual extinction of note issue by provincial banks. Though the act was perhaps unduly rigid, as was demonstrated in the commercial panic of 1847, Peel's convictions of the dangers of unsound currency made him prefer a tight system, with possible recourse to emergency measures in time of crisis, to one which provided any loophole for credit inflation. The success of his tariff changes and the buoyancy of the revenue led in 1845 to Peel's second great reforming budget. The income tax was renewed for another three years and the resultant surplus of over £3,000,000 used for an even more drastic free trade experiment, though one made in more favourable circumstances than in 1842. A large reduction was made in the sugar duties, and the excise on glass, all remaining export duties, and import duties on about 430 articles were entirely removed.

Under the impact of Peel's early measures, aided by the stimulus of expenditure on the new railroads, the years 1843–45 saw a return of prosperity under which Chartist agitation tended to die down. The Anti-Corn Law League, which in the hard times of 1842–43 had shown signs of exploiting social disorders to bring pressure on the government, turned to more constitutional electoral methods and began to prepare for the next general election. In foreign affairs relations with France improved under the conciliatory policy of the foreign secretary, the earl of Aberdeen, though important measures were put in hand during 1845 to strengthen the naval and coastal defenses of the country. With the United States the disputed boundary between Maine and New Brunswick was settled by Lord Ashburton's mission in 1842, and four years later, after a show of stiffness by both sides, the Oregon Treaty of 1846 extended the line of the 49th parallel to the Pacific with deviations which allowed Britain to retain Vancouver Island. Like Aberdeen, Peel's desire was for peace but he invariably showed a firmer attitude in foreign policy than his patient and charitable colleague. The same combination of firmness and conciliation was exhibited toward Ireland. O'Connell's movement to obtain the repeal of the Act of Union was checked in 1843 by large military reinforcements for Ireland and by the banning of the mass meeting arranged at Clontarf (October), followed by O'Connell's trial for conspiracy. Though the verdict was subsequently quashed, it proved in fact the end of O'Connell's active career. Meanwhile the royal commission under the earl of Devon was set up to enquire into landlord and tenant relations in Ireland; the Charitable Bequests Act of 1844 brought Catholic bishops into the administration of charitable funds in Ireland; and in 1845 a wider scheme of Irish education passed through Parliament. Three university colleges were set up; and despite fierce Protestant opposition a greatly increased grant was made to the Catholic seminary at Maynooth.

The development of Peel's Irish policy was cut short by the Irish famine years of 1845–48. It is clear that Peel already had in mind a further reduction in the corn tariff, but the Irish potato disease in 1845 combined with a partial failure of the corn harvest in England made suspension of the Corn Laws for an indefinite period an immediate necessity. He came to the conclusion that it was impossible to maintain them any longer. His cabinet split on the issue in December 1845 but Lord John Russell was unable to form a government. Peel returned to office and managed to carry through his repeal measure. He believed the attempt to preserve the Corn Laws in the changing social conditions of Britain would imperil the political ascendancy of the aristocracy and that the salvation of British agriculture lay not in protection but in scientific farming. Nevertheless, he had strained the loyalty of his party on various issues; many of his followers were under pressure from farmers and agricultural protection societies in their constituencies; and as soon as Parliament met, a bitter personal challenge to his leadership developed under Lord George Bentinck and Disraeli. The bill to repeal the Corn Laws was passed at the third reading in the House of Commons on June 25, 1846, by a composite majority of Whigs, Radicals, and a minority of the Conservative Party; the same day Peel was defeated on an Irish Coercion Bill by a purely tactical combination of Whigs and protectionists. He resigned on June 29. He was never again in office, though he remained a great national figure in Parliament, dedicating himself to the support of free trade principles and the maintenance of a Whig ministry as the only safeguard against a protectionist government. Despite the pleas of some of his followers, he abstained from any attempt to organize a party, and was frequently called upon by members of Russell's ministry for assistance and advice. Though he delivered the last great speech of his career on June 28, 1850, in condemnation of Palmerston's policy in the Don Pacifico incident, he was relieved at the government's avoidance of defeat. Next day, as he rode down Constitution Hill, he was thrown from his horse, breaking his collarbone and several ribs. He died on the evening of July 2, 1850, at his house in Whitehall Gardens.

Character and Political Significance.—In appearance Peel was a tall, handsome, well-built man with reddish hair and blue eyes, and was something of a dandy in his dress. He was fond of sport, an excellent shot, and capable of great physical exertion. But this solid exterior concealed a complex and self-conscious personality. A proud, shy person of scrupulous integrity and with a prickly sense of honour, he was both ambitious and idealistic in his pursuit of politics. Though trained by early experience to habitual caution and reserve, he was by nature quick-tempered, stubborn, and courageous. Ill at ease with strangers, impatient with fools and bores, he often gave an impression of aloofness and frigidity; yet with intimate friends he was lively and affectionate, and to those in trouble unusually generous and warmhearted. Endowed with a first-class intellect, an exact memory, and an immense capacity for work, he was a superb administrator and as prime minister supervised every aspect of departmental policy. In the Commons his practical knowledge, political sagacity, and persuasive debating skill made him the greatest parliamentarian of his time. Yet his stiff public manner and lack of aptitude for the lesser arts of management made it difficult for him to win the real loyalty of his followers. Subsequent criticism that he lacked foresight and "chose the wrong party," overlooked the fact that his public outlook was formed in an older and more aristocratic period of politics. Though recognizing the need after the Reform Act for government to be based on organized parties, he still held that ministers of the crown were servants of the state and not the mouthpieces of sectional interests. With those beliefs he made a more important and permanent contribution to the structure of the Victorian state than any other statesman of the period. At the same time, by insisting on fundamental changes in the national interest, he did much to preserve the continuity of aristocratic parliamentary rule in an age of social distress and class conflict. Though sometimes obstinate, his mind never lost its flexibility and imagination; the last decade of his life was coloured by his intense concern for the "condition of England" problem (*see* ENGLISH HISTORY: *The Victorian Age*). The repeal of the Corn Laws in 1846, involving him in the sacrifice of power and party, gave him a prestige with the middle and working classes that no previous minister had ever possessed; his dra-

matic death in 1850 occasioned unprecedented scenes of national sorrow. *See* also references under "Peel, Sir Robert," in the Index.

PEEL, a seaport and seaside town on the west coast of the Isle of Man, lies 10 mi. NW of Douglas by road and on the Isle of Man railway. Pop. (1961) 2,487. It is situated on Peel Bay at the mouth of the River Neb, which forms the harbour. The old town consists of narrow streets and lanes, but a modern residential quarter has grown up to the east. On the west side of the river mouth St. Patrick's Isle, connected with the mainland by a causeway, is occupied almost wholly by ruins surrounded by a 16th-century wall. The ruins include the keep and guardroom of Peel Castle and, close by, the remains of the Cathedral of St. German, including a transitional Norman choir with an early crypt beneath, and a nave with an Early English triplet at the west end. There are also remains of the bishops' palace and of the palace of the lords of Man. In 1397 Richard II condemned the Earl of Warwick to imprisonment in Peel Castle, and in 1444 Eleanor, duchess of Gloucester, received a similar sentence. Also on the island St. Patrick is said to have founded the first church in Man, and a small chapel dedicated to him appears to date from the 8th or 10th century. There is an ancient round tower.

Peel has a long-established fishing industry. It was called by the Northmen Holen ("island"; *i.e.*, St. Patrick's Isle); the existing name is Celtic, meaning "fort."

PEELE, GEORGE (1556–1596), English dramatist, predecessor of Shakespeare, who experimented in many forms of theatrical art: pastoral, history, melodrama, tragedy, folk play, and pageant. His *The Arraignment of Paris* is one of the earliest mythological pastorals, and his *Device of the Pageant Borne Before Woolstone Dixi* is the earliest surviving complete lord mayor's show, the annual pageant produced for the inaugural ceremonies of the lord mayor of London.

Peele was born in London, the eldest son of a middle-class urban family. His father, James, was an accountant and teacher who himself wrote pageants, as well as two treatises explaining double-entry bookkeeping. Shortly after George's birth James was appointed head bookkeeper of Christ's Hospital, at that time a home and school for London orphans. There the dramatist lived and studied until he went to Oxford in 1572.

What is known of Peele's career at Broadgates Hall (later Pembroke College) and Christ Church, Oxford, indicates that he began his varied literary career by translating into English one of the plays of Euripides. William Gager, the celebrated Latin dramatist, wrote two commendatory poems to the young student, praising him for his literary skill; and Anthony à Wood records that Peele was "esteemed a most noted Poet in the University."

In 1579 Peele made two trips to London. His second visit was cut short at the request of the hospital governors, who seem to have felt that the added burden of a student able to shift for himself was too distracting for the now-ailing father. Peele returned to Christ Church, where he married Anne Cooke and settled down in the university community. During this period he probably wrote the first of his surviving works, a 485-line verse epitome of the *Iliad*, titled *The Tale of Troy* (published 1589).

In 1581 he moved to London but during the next two years returned to Oxford many times to cope with litigation over property his wife had inherited. Pleasanter business necessitated his return in 1583, when Christ Church presented two spectacular plays by Gager, and Peele was hired as one of the technical directors.

About this time Peele had joined a group of Oxonians living just outside the London city wall and had begun to experiment with poetry in various metres. From this association with the so-called "university wits" comes a blank verse commendatory poem to the poet Thomas Watson and two mythological pastorals: *The Arraignment of Paris* (1584) and *The Hunting of Cupid*. This sort of gentleman's writing probably brought Peele less money than praise, for shortly afterward he produced *The Device of the Pageant Borne Before Woolstone Dixi* (1585). It was followed by other pageants for the city, of which only *Descensus Astraeae* (1591) survives.

The Arraignment of Paris was produced for the courtiers, but the rest of Peele's life was devoted to writing for the popular stage. Of the many playhouse dramas he must have had a hand in, only four can be certainly ascribed to him: *The Battle of Alcazar* (1594), *The Old Wives Tale* (1595; ed. by R. L. Blair, 1936), *Edward I* (1593), and *The Love of King David and Fair Bethsabe* (1599). To supplement a meagre income, Peele turned out poems commemorative of noteworthy events: *A Farewell* (1589), to John Norris and Francis Drake on their departure with a counterarmada to fight the Spanish; *An Eglogue Gratulatorie* (1589), to the earl of Essex on his return home from this expedition; *Polyhymnia* (1590), celebrating an important tilting match; *The Honour of the Garter* (1593), commemorating the earl of Northumberland's installation as knight of the Garter; and *Anglorum Feriae* (1595), another memorial of a noteworthy tilt. The only other work which can with any certainty be ascribed to Peele is a poem, "The Praise of Chastity," which appeared in *The Phoenix Nest* (1593), an anthology of Oxford poets.

It used to be customary to describe Peele as dissipated, depraved and desperate, but the evidence on which such an estimate of his character was largely based—an anonymous jestbook that made free use of his name—is valueless in this respect. He lived and died a varied life fraught with the perils of poverty; shortly before his death he sent his eldest daughter to Lord Burghley with a request for money, describing himself as enfeebled by long sickness. His contemporaries praised him highly. Modern critics accord him a place, along with Robert Greene, Thomas Kyd, and Thomas Nashe, as an important early playwright with considerable technical skill.

(D. H. H.)

PEEL RIVER, in northwest Canada, 425 mi. in length, rises in the Ogilvie Mountains, Yukon Territory. With its tributaries the Blackstone, Hart, Wind, Bonnet Plume, and Snake, it drains a large area of northern Yukon to the Mackenzie River which it joins near Fort McPherson. Its upper course through Peel Plateau is characterized by canyons up to 1,000 ft. deep; its lower valley, much of which is in nature reserve and game sanctuary, is wide, with braided channels, gravel bars, and small wooded islands. It was named after Sir Robert Peel. (B. V. G.)

PEERAGE (medieval Lat. *paragium*, Fr. *pairie*), the quality or status of a peer, that is, originally, in the kingdom of the British Isles and in France, of a member of the nobility entitled to a measure of personal and direct participation in the legislative or judicial deliberations of his sovereign. Though examples can be found of the word peer (Lat. *par*, Fr. *pair*) used for an immediate vassal of some lesser lord than a king (*e.g.*, of a duke or of a count) when his relation to that lord is in question, here the discussion will be concerned only with the peers of kingdoms.

THE BRITISH ISLES

Origins and History of British Peerages

The origins of the peerages of England, Scotland, and Ireland are connected in varying degrees with the development of Parliament in the three countries, the early identification of the English peerage with the history of the House of Lords being particularly striking. From the abolition of the Scottish parliament in 1707, until 1963 only 16 Scottish peers had the right to sit at Westminster, and from 1800 only 28 Irish peers were lords of Parliament. Moreover, after the establishment of the Irish Free State (now the Republic of Ireland) in 1922, no more Irish representative peers were elected; the last Irish peer to sit at Westminster died in 1961.

England.—Etymologically, peers (Lat. *pares*) are "equals," and in the Anglo-Norman period the word was invariably employed to indicate parity before the law. This early usage is illustrated in clause 39 of Magna Carta (1215), in which King John promised that "no freeman shall be taken or imprisoned, or disseised, or outlawed . . . except by the lawful judgment of his peers (*judicium pariun*)." The feudal tenants in chief of the crown were all the peers of one another, as the tenants of any lesser lord were each others' equals. Tenants owed suit of court to their lord, whoever he might be, and the tenants in chief were bound to attend the king's great council (*magnum* or *commune concilium*) when summoned. The Norman kings followed the Anglo-Saxon practice of holding such councils thrice yearly, at Easter, Whitsuntide, and Christmas; they could, of course, be held also at other times. The Norman great councils also retained some of the characteristics of the Anglo-Saxon Witan (*q.v.*), in that the kings could summon to them whom they would. But by far the greater element in the Anglo-Norman *magnum concilium* was the body of tenants in chief, among whom were numbered the earls (*q.v.*), in origin great royal officials whose titles were based on territorial possessions.

The size of the holdings of different tenants in chief varied greatly. Some great landowners held honours comprising the equivalent of two or three counties, while others held only small fiefs, perhaps granted to them or their ancestors as a reward for quite humble services. The gap between the greater and the lesser tenants in chief gradually widened (*see* BARON); Magna Carta recognized this clearly in the arrangements it made (clause 14) for the summoning of the *commune concilium*. It distinguished between archbishops, bishops, abbots, earls, and greater barons (*majores barones*), who were to be summoned individually, by writ, and "all those who hold of us in chief," who were to be summoned through the sheriffs. The greater barons became the ancestors of the peers of later days, while the rest of the tenants in chief became merged with the ordinary manorial owners; their representatives were the knights of the shire of the early medieval Parliaments who, after some hesitation, joined forces with the city and burgher representatives to form the House of Commons.

An examination of the early writs issued to individuals shows that those thus summoned to Parliament were indeed the archbishops, bishops, abbots, priors, earls, and greater barons. While the archbishops and bishops received their writs with regularity (during the vacancies caused by death, deprivation, or translation, the writs were issued to the "guardian of the spiritualities"), the summonses to heads of religious houses and to the barons were intermittent. Bishops had often begun their careers as royal clerks and their services were of great value to the crown; but heads of religious houses, on the other hand, were primarily concerned with the welfare of their order, while the influence of individual magnates was bound to vary. It seems, therefore, that the issue of writs of summons was at first entirely at the pleasure of the crown, and that in practice the decision was made in accordance with the personal and tenurial importance of the magnate concerned.

It was thus only gradually that the hereditary principle of the peerage was established. Throughout the reigns (1272–1377) of the first three Edwards, summonses were not always issued to the same baron for successive Parliaments, and it seems certain that these kings never considered that the issue of one writ to an individual bound the crown to its repetition for the rest of his life, much less to his heirs in perpetuity. But the fact that primogeniture had long been established as the normal rule of inheritance naturally affected the principle of summons. Primogeniture tended to secure estates in strict family succession; thus, if extent of possession had originally extracted a personal summons from the crown, it was likely that as successive heirs received the inheritance, they too would be similarly summoned. Gradually the free and indiscriminate choice of the crown became fettered by the principle that once a summons had been issued to an individual to sit in Parliament and he had obeyed that summons, he thereby acquired a right of summons for the rest of his lifetime; and in later years, when the doctrine of nobility of blood became established, his heirs were held to have acquired the same privilege by hereditary right.

Thus far the "peerage" depended entirely upon tenure of land and summons to a council or to Parliament by individual writ. But in 1387 Richard II introduced the practice of creating peerages by letters patent. John Beauchamp, steward of the king's household, was created "Lord de Beauchamp, Baron of Kidderminster, to hold to him and the heirs of his body." These letters patent were not founded on any right by tenure of land possessed by Beauchamp; Richard made him "for his good services . . . and for his noble descent, and his abilities and discretion, one of the peers and barons of the kingdom of England. . . ." The grant rested wholly on the grace and favour of the crown, and was a personal reward for services rendered. A hereditary barony was created which was entirely a personal dignity, quite unconnected with the tenure of land. From Richard's reign to the present day, baronies (and, indeed, all other peerage honours) have continued to be conferred by patent. The custom of summons by writ was not in any way interfered with, the patent operating merely to declare the dignity and to define its devolution. Summons alone continued for many generations side by side with summons founded on patent; but after the reign (1509–47) of Henry VIII the former method fell into disuse and since the 17th century there have been no new creations by writ of summons alone. So, from the late 14th century, barons were of two classes; the older, and more ancient in lineage, summoned by writ alone, the honours descending to heirs general; and the newer, created by letters patent, the terms of which governed the issue of the summons and prescribed the devolution of the peerage in a line usually of the direct male descendants of the person first ennobled.

It was long believed that originally there had existed peerages by tenure alone, and that such could devolve by right of tenure independent of descent. But in the Berkeley case (1858–61), when Sir Maurice Frederick FitzHardinge Berkeley unsuccessfully claimed the barony by virtue of his seisin of Berkeley Castle, it was finally determined that bare tenure could not be regarded as a means of establishing a peerage right. The main attribute of a peerage is that hereditary and inalienable quality which ennobles the blood of the holder and his heirs, or, as Sir John Doderidge put it in the case of the earldom of Oxford and the office of lord great chamberlain (1625–26), "he cannot alien or give away this inheritance, because it is a personal dignity annexed to the posterity and fixed in the blood."

Until the reign of Edward III, the peerage consisted only of prelates, earls, and barons. The earls were barons with their special name of dignity added, and their names always appear on the rolls before those of the barons. In 1337 King Edward created his son, Edward the Black Prince, duke of Cornwall, giving him precedence over the rest of the peerage. Subsequently several members of the royal family were created dukes, but no subject received such an honour until 1386, when Richard II created his favourite Robert de Vere, earl of Oxford, duke of Ireland (for life). The original intention may have been to confine the dignity to the blood royal, since, with the exception of de Vere, it was some years before a dukedom was again conferred on a subject.

Richard had previously (1385) created de Vere marquess of Dublin, thus importing into the English peerage a title hitherto unknown in that country. The grant was, however, for life only, and was in fact resumed by the crown in 1386, when de Vere was created duke of Ireland. Yet another order was added in 1440, when Henry VI created John, Baron Beaumont, Viscount Beaumont, giving him precedence next above the barons. None of these three new titles ever carried with them any official position; they were conferred as additional honours on men who were already members of the peerage.

The application of the hereditary principle to temporal peerages early differentiated their holders from the spiritual peers. Both spiritual and temporal peers were equally lords of Parliament, but the temporal peers, stressing their doctrine of "ennobled blood," gradually came to consider that they were superior to all other lords of Parliament. Eventually they arrogated to themselves the exclusive right to be called peers, and as such the

only persons entitled to the privileges of peerage. The prelates were hindered in their struggle to retain peerage privileges by the success obtained by the church in establishing certain rights, such as exemption from trial in the secular courts (*see* CLERGY, BENEFIT OF). Thus they never claimed the privilege of trial by peers, and when arraigned alleged that they were altogether beyond secular authority. The standing orders of the House of Lords for 1628 contain the statement that "bishops are only lords of Parliament, but not peers."

The reign of Henry VIII brought about far-reaching changes in the position of the peerage. At Henry's accession the hereditary element was in a decided minority, but the balance was rapidly redressed by new creations, while the dissolution of the monasteries removed from the House of Lords the heads of religious houses. The numbers of the House increased steadily throughout the Tudor and Stuart periods and from the time of William III there were recruited to the Lords a steady stream of men who had served their country well in various capacities, mainly as statesmen, judges, sailors, and soldiers.

Scotland.—The Scottish peerage, like that of England, owes its origin to feudalism. Tenants in chief of the crown owed suit of court, but only the more important were summoned personally. Generally, those so summoned were earls and barons, the "barons" being those tenants in chief who themselves were entitled to hold a court. In 1426, however, legislation of James I resulted in the appointment of "lords of Parliament" who received individual writs and were therefore distinguished from other barons. The lords of Parliament became hereditary, though the title generally passed with the land. During the 15th century other barons still attended Parliament, although it was the intention that they should be represented by commissioners of shires, and this was enforced after 1587.

When the Scottish earls and barons attended Parliament, however, they did not separate themselves from the Commons' representatives, it being the custom for the estates of Scotland to deliberate together. The territorial strength of the nobles inevitably led them to regard the honour as belonging to and inseparable from their land, and until comparatively late in Scottish history there is no record of the conferment of a personal dignity unattached to land such as that conferred in England on John Beauchamp by Richard II. This explains the frequent surrenders and altered grants which are so common in Scottish peerage and history and which, in sharp distinction to the English rule of law, are there regarded as perfectly legal.

Ireland.—The Anglo-Normans who conquered Ireland in the 12th century carried with them the laws and the system of tenure to which they were accustomed in England. Consequently the growth of the Anglo-Irish baronage and the development of Parliament in Ireland proceeded in much the same way as in England. But the Irish Parliament was rarely attended by Irish chiefs; and although intermarriage occurred, the Irish peers in Parliament were almost always representative only of the conquerors. After the Reformation had been forced upon Ireland, the abbots disappeared. The bishops became Anglican and from the 17th century onward the Irish peerage was swamped by numbers of English Protestant creations. Early in the 18th century penal laws debarred Catholics from Parliament, thus dividing the peerage. The Irish Lords, moreover, had no tradition of privilege such as that developed among their English fellows; Irish nobles could not claim trial by their peers.

The United Kingdom.—The acts of union with Scotland (1707) and with Ireland (1800) respectively abolished the Parliaments of these countries, providing instead for their representation in the Parliament, first of Great Britain, and then of the United Kingdom. But whereas before the union the lords of Parliament in Scotland and all the peers in Ireland had a right to attend their Parliament, after the union only a certain number went to Westminster. The Scottish act gave to the Scottish peers the right to elect 16 of their number to represent them in the House of Lords. Further creations in the Scottish peerage were no longer to be made. The effect of the act was to leave most of the Scottish peers outside the House of Lords. By the Irish Act of Union 28 Irish peers were to be elected for life by the other peers, to represent them at Westminster. One archbishop and three bishops were also chosen to represent the Protestant Church of Ireland, but when that church was disestablished in 1869, the spiritual lords lost their seats.

The merger of the three kingdoms had an important effect on their peerages. The English peer (and, as the Acts of Union were passed, the peer of Great Britain and the peer of the United Kingdom) continued by hereditary right a lord of Parliament. But the Scottish and Irish peers were henceforth lords of Parliament only when elected by their fellow peers. They retained every other privilege of the peerage, however, and the 1963 Peerage Act admitted all peers of Scotland (no longer just the 16 elected) to be members of the House of Lords.

The establishment in 1922 of the Irish Free State, which became the Republic of Ireland in 1949, indirectly but vitally affected the status of the Irish peerage. This peerage belonged to the old united Ireland and could not arbitrarily be divided between its two halves. The Irish Free State Constitution Act of 1922, together with various other acts dependent thereon, destroyed the procedure by which Irish representative peers were elected; whether intentionally or by accident is not known. Existing representative peers, having been elected for life, remained in the House of Lords until their deaths, but no vacancies could be filled. The Irish peerage thus disappeared from Parliament after the death of the last representative peer in 1961. The peerage itself, like that of Scotland, will also slowly diminish as existing peerages become extinct, and no new Irish creations are made.

THE PEERAGE IN THE MID-20TH CENTURY

The modern meaning of the term "peerage" can now be more clearly defined. It will be noted that there have always been separate peerages of England, Ireland, and Scotland. After the union of England with Scotland new creations became of the peerage of Great Britain, and after the union of Great Britain with Ireland, of the United Kingdom of Great Britain and Ireland. After 1922 it was correct to speak of "the United Kingdom of Great Britain and Northern Ireland." Many members of the House of Lords hold peerages in several of these groups, but they use publicly only the title which is first in point of precedence. Every peerage descends according to the limitations prescribed in its patent of creation or its charter, and, where these are nonexistent (as in the case of baronies by writ), to heirs general (*see* ABEYANCE).

There is no limit on the crown as to the number of United Kingdom peerages which may be created. Since party government became the rule, new peerages have usually been created on the recommendation of the prime minister of the day, though the crown, especially in considering the claims of royal blood, is believed in some instances to take its own course. By far the greater number of peerage honours granted since the beginning of the 18th century have been rewards for political services. Until the Parliament Acts of 1911 and 1949 reduced the power of the House of Lords, the threat of mass creations was the only way to force the Lords to pass certain bills. This was done in the case of the 1832 Reform Bill and for the passage of the Parliament Act of 1911.

The House of Lords in the 1960s consists of about 900 lords spiritual and temporal. The former are the archbishops of Canterbury and York, the bishops of London, Durham, and Winchester, and the 21 senior bishops from the other dioceses. The temporal peers are the peers of England, of Scotland, of Great Britain, and of the United Kingdom, peeresses in their own right (since 1963), the 9 lords of appeal in ordinary (who are life peers), and (since 1958) life peers and life peeresses.

Life Peers.—Life peers were sometimes created during the later Middle Ages, but such grants were usually in the form of further honours given to persons already members of the peerage. The creations of Robert de Vere, earl of Oxford, as marquess of Dublin and duke of Ireland were for life only. But such creations were infrequent and the attempt made in 1856 (the Wensleydale Peerage Case) to create one of the judges a life peer was rejected by the House of Lords. But in 1876 legislation was passed creating two lords of appeal (with power to appoint two more) with a right

to sit and vote during their tenure of office only. In 1887 further legislation conferred life peerages on all lords of appeal and former lords of appeal. The number of lords of appeal in ordinary who may hold office at any time is now fixed at between 8 and 11. The Life Peerages Act of 1958 permitted the creation of life peerages for men and for women, carrying the right to sit and vote in the House of Lords. Although by this act women were allowed to sit in the Lords, the bar against peeresses in their own right remained until the Peerage Act of 1963. In the mid-1960s an average of about nine life peerages were created each year.

Privileges of the Peerage.—Many privileges once keenly asserted have now fallen out of use or been forgotten. The most important privilege now remaining is a seat in the House of Lords. Lords of Parliament have freedom of speech in Parliament. Peers also have a right of personal access to the sovereign and are exempt from jury service. Until the Criminal Justice Act of 1948, in cases of treason and felony, they had the right of being tried by their peers only. The last trial of a peer by his fellow peers was that of Lord de Clifford in 1935. As late as 1962, however, a peer successfully claimed his privilege of immunity from attachment, *i.e.*, arrest in a civil case.

Termination of Peerages.—Peerages can be terminated by surrender or by attainder and corruption of blood. The application of the doctrine of corruption of blood to peerages arises out of their close connection with the tenure of land. Conviction of any kind of felony—and treason originally was a form of felony—was always followed by attainder (*q.v.*). This resulted in the immediate corruption of the blood of the offender; its capacity for inheritance was lost forever and could only be restored by act of Parliament. This stringent rule of forfeiture was to some extent mitigated by the promulgation in 1285 of the statute *De Donis Conditionalibus* (*see* ENTAIL), making possible the creation of estates tail, and when a tenant in tail was attainted, forfeiture extended only to his life interest. The statute was soon applied by judges to such dignities as were entailed (*i.e.*, dignities conferred by patent with limitations in tail), but it never affected baronies by writ which were not estates in tail but in the nature of estates in fee simple descending to heirs general. An act of 1534 brought estates tail within the law of forfeiture, but for high treason only. The position then became that peerages of any kind were forfeitable by attainder following high treason, while baronies by writ remained, as before, forfeitable for attainder following on felony. An act of 1708 determined that, on the death of James Edward, the Old Pretender, and three years after Queen Anne's death, the effects of corruption of blood consequent on attainder for high treason were to be abolished and the offender alone punished (7 Anne, cap. 21, sec. 10). Because of the 1745 rebellion the operation of this act was postponed until the decease not only of the Pretender but also of all his sons (17 Geo. II, cap. 39, sec. 3). In 1814 forfeiture for every crime other than high and petty treason and murder was restricted to the lifetime of the offender (54 Geo. III, cap. 145). Finally, in 1870, forfeiture, except upon outlawry, was altogether abolished, and it was provided that "no . . . judgment of or for any treason or felony . . . shall cause any attainder or corruption of blood, or any forfeiture or escheat . . ." (33 and 34 Vict., cap. 23).

In many cases, from the 15th to the 18th century, special parliamentary acts of attainder and forfeiture were passed and these operated apart from the general law. In any case, attainder and forfeiture of a dignity, whether resulting from the rules of common law or from special or general acts of Parliament, can be reversed only by act of Parliament.

From the doctrine of nobility of blood is derived the rule of law that no peerage (apart from a Scots peerage, Scots law admitting surrender) can be surrendered or extinguished unless the blood be corrupted. Nevertheless, in medieval times many surrenders were made. By a decision (1906) of the Committee for Privileges, any heirs of line of those who thus got rid of their peerages have, if their pedigrees be provable and no attainders bar the way, a fair chance of reviving the titles. By the Peerage Act of 1963 existing peers were allowed to surrender their peerage for life only, provided they did this within six months of the passage of the act. Persons succeeding to a peerage were to be allowed one year in which to make the decision. Peerages which are thus surrendered remain dormant until the decision of the next heir whether or not also to surrender.

Claims to Peerages.—Claims to peerages are of two kinds, of right and of grace. In theory the crown, as the fountain of honour, might settle any claim without reference to the House of Lords and issue a writ of summons to its petitioner. This would not in any way prevent the House of Lords from examining the patent and writ of summons when the petitioner or his heir came to take his seat. If of the opinion that the patent was illegal, the House might refuse admission, as it did in the Wensleydale Case. In the case of a petitioner who has persuaded the crown to terminate in his favour as a coheir the abeyance of an ancient barony, and who has received a writ of summons, the matter is more difficult. The House cannot refuse to admit any person properly summoned by the crown, as the prerogative of creation is unlimited in point of numbers; but it can take into account the precedence of the newcomer. The crown, therefore, rarely terminates an abeyance without referring the matter to the House of Lords and invariably refers to it all claims which are disputed or involve any question of law.

The Committee for Privileges, which for peerage claims is usually constituted of three or more of the law lords and any other lords interested in peerage history, sits as an ordinary court of justice and follows the usual rules of law and evidence. The attorney general attends as adviser to the committee and to watch the interests of the crown. According to the nature of the case, the committee reports to the House, and the House to the crown, that the petitioner (if successful) has made out his claim and is entitled to a writ of summons, or has proved his coheirship to an existing peerage and has also proved the descent of all coheirs that can reasonably be traced. In the first case the writ of summons is issued forthwith; but the second, being one of abeyance, is a matter for the pleasure of the crown which need not be exercised at all, but, if exercised, may terminate the abeyance in favour of any one of the coheirs. In 1926 the House of Lords appointed a select committee to examine the history of abeyant peerages and to report on the advisability of limiting future claims. After debate on the report, the House resolved (1927) that such claims ought not to be considered where the abeyance had existed for longer than a century, and where the claimants possessed only a small fraction of the original heirship. The resolution was duly reported to the crown and although such recommendations cannot in law affect the crown's prerogative to terminate any abeyance, they would have some weight.

In addition to those peerages which have fallen into abeyance between coheirs, there are dormant peerages which are in a state of suspense. Such titles have not become extinct, but no person has been able to prove succession. The expression, therefore, should be taken to indicate that the title is one to which it is thought that an heir exists, but his whereabouts is unknown; or that there are persons living who are undoubtedly in the line of succession, but through lack of evidence cannot prove the extinction of senior lines; or that the claim of some individual has not been accepted because proof of his legitimate descent has not been produced.

Precedence.—Dukes come first in the order of precedence among peers, followed by marquesses, earls, viscounts, and barons. In each order seniority is determined by the original date of creation. The premier duke of England is the duke of Norfolk (created 1483), of Ireland the duke of Leinster (1766), and of Scotland the duke of Hamilton (1643). The premier marquess of England is the marquess of Winchester (1551), and of Scotland the marquess of Huntly (1599). The earl of Shrewsbury (1442) and of Waterford (1446) is the premier earl of both England and Ireland; the premier earl of Scotland is the earl of Mar (1404). The premier viscount of England is Viscount Hereford (1550), and of Ireland Viscount Gormanston (1478). The premier barony of England (now held by a woman) is de Ros (1264); the premier baron of Ireland is Baron Kingsale (*c.* 1340), and of Scotland Baron Forbes (1424).

The children of peers are commoners. The eldest son of a peer of the rank of earl (and above) is usually known socially by the name of his father's next peerage, but the courtesy nature of such title is clearly indicated on every public or legal document, the phraseology employed being (*e.g.*) "John Smith, Esq., commonly known as Viscount Blackacre." Several cases are on record in which peers' eldest sons have actually borne courtesy titles not possessed as peerage honours by their fathers, but inasmuch as such are only accorded by courtesy, no question of peerage privilege arises. The younger sons of dukes and marquesses by custom use the prefix "lord" before one of their Christian names, and all the daughters of earls as well as of dukes and marquesses are entitled similarly to style themselves "lady," on the principle that all the daughters are equal in rank and in precedence. The younger sons of earls and all the children of viscounts and barons, including lords of appeal and life barons and baronesses, use the prefix "honourable" before one of their Christian names, but this style is one of written address and reference only. Usually, when the direct heir of a peer dies, his children are given by the crown, on the death of the peer, the courtesy titles and precedence they would have enjoyed had their father actually succeeded to the peerage. (C. F. J. H.)

FRANCE

The Peerage of the Old Monarchy.—The peerage of France does not become clearly defined as an institution till the 14th century, and its origins are still problematic.

In feudal society, one of the meanings borne by the word *pares* (Fr. *pairs*) was that of vassals of the same lord (*see* FEUDALISM). It could thus be applied to all those immediate vassals of the king who might attend his court of government, the *curia regis*, to assist him there, *inter alia*, in his function as supreme administrator of justice and so to take cognizance of cases concerning any one of their number. It is in this sense that the word must be understood where it occurs in the letter of *c.* 1022–23 addressed by Eudes II, count of Blois and of Chartres, to King Robert II (this letter was most probably composed by the bishop of Chartres, Fulbert).

At the same time the word *pares* was likewise used to denote those vassals of the counts of Flanders, of Hainaut, and of Champagne who particularly assisted the counts or their chatelains in dispensing justice; and here these *pares* are most often found to be 12 in number. This number is best regarded as preserving a tradition from the Carolingian period, when counts had 12 *scabini* (local magistrates) to assist them; and in fact this tradition survived in another form in the *échevinage* (*see* COMMUNE [MEDIEVAL]) in some of the towns of the same area.

Such was the way in which the word *pares* was being used by the beginning of the 12th century, that is to say at the time of the composition of the *Chanson de Roland*, which is the earliest text to refer to "the 12 peers" of the Frankish kingdom, meaning the principal companions of Charlemagne. In documents of the same period, however, the expression *majores pares* ("greater peers"), combining the notion of superiority with that of equality, is applied to the principal vassals of the king. Yet there is no mention of peers of France in the earliest extant account of a French king's *sacre* or coronation, namely Philip I's (1059); and the role eventually assigned to the peers at coronations was a later development, representing moreover their duty of homage, not any privilege. This role was not defined till the coronation of Philip V (1317).

It was during the 13th century that the peerage began to take shape as an institution, albeit within narrow limits. The old story that Philip II Augustus took a formal verdict from a judicially constituted "court of peers" before he deprived the English king John of his French fiefs in 1202 is now quite discredited (Philip merely consulted his barons before starting war against John); and there is no substance in the story of a trial of John by a similar court for the murder of Arthur of Brittany in 1203. The first authentic mention of the peers of France dates from July 1216, when on the occasion of the lawsuit between Blanche, countess of Champagne, and Erard of Brienne, the title "peers of our realm" is used to describe the archbishop of Reims, the bishops of Langres, Châlons, Beauvais, and Noyon, and the duke of Burgundy.

It is not till 1275 that there is any official listing of the 12 peers of France, when an ordinance of Philip III on mortmain dues exempts (1) the six ecclesiastical peers, the archbishop-duke of Reims, the bishops-dukes of Laon and Langres, and the bishops-counts of Beauvais, Châlons, and Noyon; and (2) the six lay peers, the dukes of Aquitaine, Burgundy, and Normandy and the counts of Champagne, Flanders, and Toulouse. This list, however, merely echoes an enumeration made in the middle of Louis IX's reign by the chronicler Matthew Paris without any known authority from the king, obviously in an attempt to establish a symmetrical correspondence between peerages and titles. By 1275 the list was already out of date, since both Normandy and Toulouse had been reunited to the French crown. When Philip IV in 1297 recognized the duke of Brittany and the counts of Anjou and Artois as peers it is not at all likely that he was concerned about restoring a fixed total of 12 peerages (though the old list was by that time even more remote from reality, in view of the contumacy of the king's vassals in Aquitaine and in Flanders).

It is certain that some of the major vassals of the kingdom sought to assert a right to be tried only by a court composed of their equals exclusively; but successive kings steadfastly refused to allow this privilege. Philip V did however admit, during the trial of Robert III of Artois (1316), that "to take cognizance . . . of the cases of peers of France, the court of *parlement* should be reinforced by peers of France" (*paribus Francie munita*); and thereafter *"la cour garnie de pairs"* was the only formula acknowledged (*see* PARLEMENT).

Peerage was thereafter an honorific distinction only, without political significance; and from 1327 the kings bestowed this supreme dignity without any regard to limiting the number of peers, so that creations, extinctions, and revivals intermingle chronologically. At first peerage was bestowed only on princes of the Capetian blood royal, but later it was extended to foreign princes who held fiefs in France and finally to lesser French nobles whom the kings wanted to elevate. There was only one addition, however, to the ecclesiastical peerages, the archbishop-duke of Paris (1674). By the beginning of the 16th century it was usual for new peerages to be associated with duchies (*see* DUKE), though occasionally a peerage might be granted with the revived title of some particularly venerable countship, such as Toulouse. The 16th and the 17th centuries were the most prolific in peerages.

The 19th Century.—The French Revolution abolished the old peerage. The Chamber of Peers, established at the first Restoration by the constitutional charter of 1814 as the upper house of a bicameral legislature, introduced a peerage of a very different sort. Apart from the princes of the blood royal, its members were nominated by the king; their number was theoretically unlimited; their peerages could be either hereditary or for life only, as the king wished; and the majority of the members nominated by Louis XVIII in fact came from the Napoleonic Senate of the Empire. The chamber's deliberations were secret; and it could be empowered by the king to sit as the Court of Peers to try cases of high treason or crimes against state security, as well as charges brought against a peer.

During the Hundred Days a Chamber of Peers was instituted by Napoleon's *Acte additionnel* (1815), with hereditary peerage for its members. The second Restoration brought back the Chamber of Peers of 1814, with the difference that peerage was made hereditary (August 1815). Under the July Monarchy the principle of hereditability was abolished (December 1831). After the revolution of 1848 the Second Republic abolished the Chamber of Peers.

PEERSON, MARTIN (*c.* 1572–1650), English composer of vocal and instrumental music, born in Cambridge about 1572. In 1613 he took the bachelor of music degree at Oxford University; it is probable that he was then master of the choristers at St. Paul's Cathedral, London, a post he apparently held until his death in London in December 1650.

Peerson published two volumes of his own works: *Private Musicke* (1620), a collection of airs for voices and instruments; and *Mottects or Grave Chamber Musique* (1630), for voices and instruments and including a figured bass part. His work surviving in manuscript includes sacred vocal music to English and Latin texts; secular vocal music; several pieces for viol consort; and four keyboard pieces in the *Fitzwilliam Virginal Book*.

PEGASUS, the winged horse of Greek mythology, sprung from the blood of Medusa as she was beheaded by Perseus. With Athena's (or Poseidon's) help Bellerophon captured Pegasus drinking at the Corinthian spring Pirene, and rode him in his fight with the Chimera, and while taking vengeance on Stheneboea (alias Anteia; *see* BELLEROPHON). Subsequently Bellerophon attempted to fly with Pegasus to heaven but was unseated and killed, the winged horse becoming a constellation in the sky and the servant of Zeus. Hippocrene, on Mt. Helicon, was the most famous of the springs which rose where Pegasus' hoof had struck the earth. Corinth, whose early coinage regularly bears the device of Pegasus, has numerous points of contact with his story, and was probably the intermediary by which it was transmitted from the Middle East to Greece, in whose art and literature it became a favourite theme. Pegasus' soaring flight was interpreted as an allegory of the soul's immortality in late antiquity; it has been regarded as a symbol of poetic inspiration in modern times. (D. E. W. W.)

PEGASUS (THE WINGED HORSE), in astronomy, a constellation that appears in the south during autumn evenings for observers in the middle northern latitudes. Named for the winged horse of Greek mythology, its conspicuous geometrical figure is the "Great Square of Pegasus," which has at its corners three bright stars of this constellation and one of Andromeda. The vernal equinox, the sun's location when spring begins, is not far south of the square. To locate features of this area, it may be convenient to imagine that the square is the bowl of a large dipper, having as its handle the line formed by three bright stars of Andromeda and a fourth star in Perseus.

PEGMATITE, a name originally given by French mineralogist René Haüy (1743–1822) to masses of granite characterized by coarse crystals of alkali feldspars with regular intergrowths of quartz, giving an appearance suggesting cuneiform characters (graphic granite). Later usage of the term has been much broadened to include almost any wholly crystalline igneous or metamorphic rock that is at least in part very coarse grained, whose major constituents include minerals typically found in ordinary igneous rocks, and in which extreme textural variations, especially in grain size, are characteristic. Giant crystals, with dimensions measured in feet or yards, occur in some pegmatites, but the average grain size of all such rocks is only three or four inches.

Pegmatites are little different from the common igneous rocks in major elements of bulk composition, and they range from acid to basic. Granitic and syenitic types are most abundant. Quartz and alkali feldspars are the essential constituents; the most common varietal and accessory minerals are muscovite, biotite, apatite, garnet, and tourmaline. Many granitic pegmatites contain various minerals that bespeak unusual concentrations of the less abundant elements, *e.g.*, beryllium in beryl, chrysoberyl, phenacite; boron in tourmaline, axinite; fluorine in apatite, micas, topaz, tourmaline; lithium in lepidolite, spodumene, several phosphate minerals; rare alkalies in pollucite, beryl, feldspars, micas; tin in cassiterite; tungsten in wolframite; zirconium in zircon; and tantalum, niobium, uranium, thorium, and rare earths in many oxide and phosphate minerals (*see* GEOCHEMISTRY: *Residual Melts and Solutions*).

Most bodies of pegmatite are tabular, podlike or irregular in form, and range in size from single crystals of feldspar to dikes hundreds of feet thick and nearly a mile long. Many are intimately associated with masses of fine-grained aplite (*q.v.*). They are found in terranes of igneous and metamorphic rocks in all parts of the world, and are most abundant in rocks of relatively great geologic age. Some are segregations within much larger bodies of intrusive igneous rocks, others are distributed satellitically in the rocks that surround such bodies, and still others are not recognizably associated with igneous rocks.

Granitic and syenitic pegmatite deposits are the chief source of commercial feldspar, sheet mica and beryllium, tantalum-niobium, and lithium minerals. They also yield significant quantities of cassiterite, gem minerals, scrap mica, molybdenite, tungsten minerals, rare-earth minerals, zircon, and certain types of kaolin, either directly or as the sources of placer deposits. Economic lode concentrations generally occur in zoned pegmatite bodies; *i.e.*, those within which two or more different rock types are systematically disposed.

Three contrasting mechanisms together account for the origin of most pegmatites: (1) replacement of preexisting nonpegmatitic rocks through the action of various fluids; (2) crystallization of silicate melts derived by partial fusion of preexisting rocks; and (3) crystallization of residual fluids developed during late stages in the consolidation of intrusive magmas. The first process is essentially metamorphic, the others mainly igneous. The presence of water and other volatile substances seems necessary, and probably is common to all three processes; such constituents depress the temperature range of crystallization, participate directly in the formation of many minerals and lower the viscosity of igneous melts, thereby promoting formation of large crystals. Experimental evidence indicates that the presence of a separate vapour phase is necessary for development of the giant crystals found in pegmatites.

Features indicating replacement of one mineral by another are widespread within many bodies of pegmatite. Most are attributable to attack of earlier-formed minerals either by residual liquid, by vapour separated from the liquid, or by liquid condensed from such vapour. The end stages of some pegmatite crystallization are marked by development of well-faced transparent crystals, commonly as linings and partial fillings of cavities. Such occurrences have yielded handsome mineral specimens, as well as apatite, beryl, chrysoberyl, corundum, feldspars, garnets, phenacite, quartz, scapolite, spinels, spodumene, topaz, tourmaline, and zircon of gem quality.

Ore minerals, chiefly sulfides and oxides, are widespread in pegmatites, but rarely are abundant. The origin and behaviour of ore-forming fluids derived from magmas (*see* ORE DEPOSITS) probably are intimately related to the processes responsible for development of pegmatites. For discussion of replacement and other mechanisms referred to above *see* METASOMATISM; MINERALOGY; PETROLOGY. (R. H. J.)

PEGOLOTTI, FRANCESCO BALDUCCI (*fl.* 1315–40), Florentine merchant and writer whose *Pratica* gives an excellent picture of contemporary trade and travel, was a factor in the service of the mercantile house of the Bardi. In this capacity he was at Antwerp from 1315 (or earlier) to 1317; in London in 1317; in Cyprus from 1324 to 1327, and also in 1335, when he obtained from the king of Little Armenia (*i.e.*, medieval Cilicia, etc.) a grant of privileges for Florentine trade. Between 1335 and 1343, he compiled his *Libro di divisamenti di paesi e di misuri di mercatanzie e d'altre cose bisognevoli di sapere a' mercatanti*, commonly known as the *Pratica della mercatura*. Beginning with a sort of glossary of foreign terms then in use for all kinds of taxes or payments on merchandise as well as for "every kind of place where goods might be bought or sold in cities," the *Pratica* next describes some of the chief trade routes of the 14th century, and many of the principal markets then known to Italian merchants; the imports and exports of important commercial regions; the business customs prevalent in those regions; and the comparative value of the leading moneys, weights and measures.

There is only one manuscript of the *Pratica*, in the Riccardian

Library at Florence, and one edition of the text, in volume iii of Gian Francesco Pagnini's *Della Decima e delle altre gravezze imposte dal comune di Firenze* (Lisbon and Lucca—really Florence—1766); Sir Henry Yule, *Cathay and the Way Thither*, ii, 279–308, translated into English the most interesting sections of Pegolotti (Hakluyt Society, 1866).

See also C. R. Beazley, *Dawn of Modern Geography*, vol. iii (1906). (A. M. F.)

PEGU, a town and former capital of Lower Burma, giving its name to a district and a division. The town is situated on a river of the same name, 47 mi. (76 km.) NE of Rangoon by rail. Pop. (1953) 47,378. It is still surrounded by the ruins of its old wall and moat, which formed a quadrilateral, each side a mile and a half long. Its ancient Mon pagoda, the Shwemawdaw, 288 ft. (88 m.) high, was severely damaged by an earthquake in 1930, but its restoration was completed in April 1954. West of the modern town is a colossal reclining figure (Shwethalyaung) of Gautama Buddha, 181 ft. (55 m.) long, and near it the famous Kalyani Sima or "hall of ordination" founded by the Mon king Dammazedi (1472–92), from which spread one of the greatest reform movements in Burmese-Buddhist history. Its story is related in ten stone inscriptions erected by the king close to the Sima.

The most likely date of its foundation as the capital of a Mon kingdom is A.D. 825. The earliest mention of the kingdom was by the Arab geographer Ibn Khurdadhbih shortly before 850; he called it Raman'n'adesa (the *Rmen* or Mon land). Thaton, about 80 mi. (129 km.) SE on the far side of the Sittang estuary, was the Mon capital when the kingdom was conquered by the Burmese of Pagan in 1056. Little is heard of Pegu until after the fall of Pagan to the Mongols in 1287, when the Mons recovered their independence. In 1369 King Binnya U made it his capital, and from then until its capture by the Burmese king Tabinshwehti in 1539 Pegu was famous both for its Buddhist culture and for its extensive commerce. The kings of the Burmese Toungoo dynasty made it their capital from 1539 to 1599 and again from 1613 to 1634 and used it as a base from which to invade Thailand. Of the many Europeans who visited it during that period the Venetian Caesar Frederick (1569) and the Englishman Ralph Fitch (1587–88) described it in detail and stressed its magnificence. When the Burmese capital was moved up to Ava in 1634 Pegu was for a century a mere provincial capital. In 1740, however, a successful revolt made it again the capital of a Mon kingdom, but in 1757 the Burmese king Alaungpaya captured it, destroyed everything except its religious buildings, and wiped out the last vestiges of the Mon independence. In 1852 the British annexed the province of Pegu, and in 1862 the province of British Burma (later Lower Burma) was formed with Sir Arthur Phayre, the historian of Burma, as chief commissioner, the capital being moved from Pegu to Rangoon.

PEGU DISTRICT, formed in 1883, consists of a portion of the forested Pegu Yomas and an alluvial tract between the Pegu Yoma range and the Sittang River. Area, 4,824 sq.mi. (12,494 sq.km.). Pop. (1962 est.) 897,395. Almost the only crop grown is rice, which is exported in large quantities to Rangoon. The district is traversed by the railway, and also crossed by the Pegu-Sittang canal, navigable for 85 mi. (137 km.) with locks.

PEGU DIVISION comprises the districts of Rangoon town, Hanthawaddy, Insein, Tharrawaddy, Pegu, and Prome, lying east of the Irrawaddy. Area 19,423 sq.mi. (50,306 sq.km.); pop. (1962 est.) 4,650,300. (D. G. E. H.)

PÉGUY, CHARLES (1873–1914), French poet and philosopher who was an outstanding member of the brilliant generation of 1890, to which Claudel, Gide, Proust, and Valéry also belonged. His writings were intimately bound up with his personality and his life and work both exemplify the writer deeply involved in the life of his times, and illustrate the French intelligence at grips with the social and spiritual problems of the years before World War I.

Charles Péguy was born at Orléans on Jan. 7, 1873. His parents were poor; his father died young and his mother made a living as a chairmender. He was strictly brought up, both by his schoolmasters, with their stern, secular morality, and by the parish priests from whom he received religious education (*cf.* the autobiographical pages in *Pierre*, 1898, and *L'Argent*, 1913). The legacy from this upbringing was a love of hard work, of the land, of purity, of France (an essential strand in his development was that Orléans was a centre of devotion to Joan of Arc), of the republic, of truth, and a distrust of every manifestation of spiritual oppression and political tyranny. A scholarship to the *lycée* opened his mind to the riches of humanist culture—to the Greek poets and philosophers as well as to Ronsard, Corneille, and Hugo, who were to become his masters in poetic composition.

After military service (1892–93), in 1894 he entered the École Normale Supérieure at Paris, intending to become a teacher of philosophy. This he conceived as his primary vocation and, in spite of appearances to the contrary, he remained faithful to it; his last books were devoted to Descartes and Henri Bergson.

But at this point in his life two crucial events intervened. First, in 1895, he turned, with all the force of a conversion, to Socialism as the sole means by which poverty and destitution in the modern world could be overcome. The social and political outlook of the Catholic Church, as well as acute intellectual difficulties with such doctrines as that of Hell, caused him to abandon religious practice and even, as he then thought, religious faith. It was at this point that, with an enthusiasm religious in its fervour, he wrote his "first" *Jeanne d'Arc* (1897), a dramatic trilogy dedicated to those who desired to labour "for the advancement of a universal socialist republic." This vast work, utterly unsuited to the stage though brimming over with treasures of thought and expression, was an affirmation of principles he was never to deny. He also wrote, at the same period, two theoretical expositions of his Socialism: *De la Cité socialiste* (1897) and *Marcel, premier dialogue de la cité harmonieuse* (1898). In October 1897 he married Charlotte Baudouin; significantly, it was a civil marriage. She brought him a dowry which enabled him to found the Librairie Socialiste, and he gave up his ambition of a university career.

The second event which greatly affected him was the *"Affaire Dreyfus"* (*see* DREYFUS, ALFRED) which became a matter of impassioned public controversy at the beginning of 1898. Péguy threw himself unreservedly into the battle for Dreyfus' innocence and, despite strong opposition from the Socialist leaders, ranged his party on the same side. He explained his position in *Notre Jeunesse* (1910), maintaining that he had engaged himself in the *"immortelle affaire"* as a Socialist, a patriot and a Christian. This book, although not published until long after the controversy, was completely in line with the articles written between 1895 and 1899, and is one of the keys to Péguy's mind. The antagonism of the party leaders, particularly Jules Guesde, brought about a dramatic split, at the end of 1889, between Péguy and the party. When accused of anarchism he replied that he was the servant of truth and claimed the right to witness to truth as he saw it. This was the first appearance in the political and literary history of France of the *"homme libre en face du Parti."* Péguy's first act at this juncture was to found the *Cahiers de la Quinzaine* (vol. i, January 1900) which, though never reaching a wide public, exercised a profound influence on the intellectual life of France for 15 years. All the famous writers of the time contributed to it: Anatole France, Henri Bergson, Jean Jaurès, Romain Rolland, the brothers Tharaud, etc. Péguy himself published in it a large number of polemical articles, which still retain a lively interest; his style has a strength, vivacity, and imaginative and percussive power which transcends contemporary controversy. Péguy and those who supported him fought for truth, justice, and liberty. He attacked imperialism and colonialism, the anti-Catholic persecution known as *"combisme,"* the deceits and compromises of parliamentary socialists and demagogues, the anti-militarists who refused to acknowledge *"maîtresse realité"* (*cf. Notre Patrie*, 1905), and the *"parti intellectuel"* which he accused of seeking a domination both temporal and spiritual (*cf.* the four essays published as *Situations* and *L'Esprit de système*, 1906–08).

During these years he was also developing and deepening his own philosophical thought, in which Bergson's philosophy played a determinant role. He discovered—or rediscovered—a reality at the centre of which was the "natural" mystery of "incarnation." This was the only path by which he could rediscover the profound truth of the Christian religion to which he had never really ceased

to adhere, and which is itself founded on a supernatural Incarnation.

This development in Péguy's thought is illuminated in his later books: *Clio I* (1909, published 1955), *Un Nouveau Théologien* (M. Fernand Laudet) (1911), *Clio II* (1912), and the unfinished *Note conjointe sur M. Descartes et la philosophie cartésienne* (1924). And from 1910 onward the writing of poems accompanied these essays and the constant labour entailed in editing the *Cahiers;* this return to poetry was a return to his first literary vocation, and in these poems he began a new career. They were: *Le Mystère de la charité de Jeanne d'Arc*, a mystical meditation which enlarges upon some of the first scenes in the *Jeanne d'Arc* of 1897; *Le Porche du mystère de la deuxième vertu* (1911); the *Mystère des Saints Innocents* (1912); the *Tapisseries de Sainte-Geneviève et de Notre-Dame* (1912–13) which includes the well-known "La Présentation de la Beauce à N. Dame de Chartres," and, finally, *Eve* (1913), resembling in structure and scope some vast cathedral, in which, in 4,000 alexandrines, Péguy sees the human condition in the perspective of the Christian revelation.

It is impossible to entertain doubts of the authenticity and orthodoxy of Péguy's thought and religious feeling. Yet for personal reasons and chiefly because his wife remained an unbeliever he refused to have his marriage blessed or his children baptized, and this was a great grief to him in his last years. This grief was aggravated by the incomprehension with which Catholics regarded his poems, disconcerted as they were by the novelty of his poetic style—his use of *vers libre* or the *verset* and his idiosyncratic technique of verbal repetition. He also aroused their hostility by his refusal to be annexed by politicians both secular and religious, Charles Maurras and Albert Sorel for example, of the extreme right wing (*cf. Notre Jeunesse* and, more particularly, *Un Nouveau Théologien*). His unequivocal reply to his fellow-Catholics was: "I will never deny a single atom of my past." Thus, little by little, he became imprisoned in solitude, even at the time when he was writing his finest work. This was all the more serious because during the same period he felt constrained to fight, with growing intensity, his adversaries of the left on the question of the German peril; against them, and against Jean Jaurès (*q.v.*) in particular, he wrote the most savage of his pamphlets: *L'Argent suite* (1913).

In the midst of these trials Péguy the man had to suffer a further ordeal, and one of such emotional and spiritual conflict that he touched the frontiers of despair. He loved, and was loved by, a young girl, but he refused to make her either his wife or his mistress. This personal drama, of which the details are unknown, gave a new and quieter accent, like that of the tender light of dawn, to the *Mystère des Saints Innocents* and the *Deuxième Vertu* which celebrate an *"espérance espérée,"* and to the *Ballade du coeur qui a tant battu*, a long sequence of quatrains that remained unpublished until 1942. This personal grief is also reflected in *Clio II* where certain pages, written with wry self-knowledge, evoke the *"secret des hommes de 40 ans,"* but above all it shines through the "Prières dans la Cathédrale" where, at last in full possession of Hope, he sings the ineffable joys of the *"Résidence,"* of Peace restored.

Charles Péguy, serving with the French Army, was killed on Sept. 5, 1914, in the Battle of the Marne.

PEI-HAI, known as PAKHOI in Cantonese, a fishing port of Kwangtung Province, south China, on the Gulf of Tonkin, 483 km. (300 mi.) WSW of Canton. The port was opened to foreign trade by the Chefoo Convention of 1876, and in the succeeding period a considerable traffic was developed by coolies and transport animals between Pei-hai and the Hsi Chiang Valley of Kwangsi Province. As additional treaty ports were opened at Meng-tzu in 1889 and Wuchow in 1897, more convenient routes became available to the interior and Pei-hai declined. It serves mainly as a fishing and local trade centre. The population in 1953 was estimated at between 50,000 and 100,000. (T. Sd.)

PEINE, a town of West Germany in the *Land* (state) of Lower Saxony (Niedersachsen), Federal Republic of Germany, lies 24 km. (15 mi.) WNW of Brunswick by road. Pop. (1961) 29,836. Peine has few buildings of interest except the new town hall (1959). It is on the main railway and trunk road from Hanover to Berlin, on the Mittelland Canal, and near the Berlin-Ruhr Motorway. Eddesse Airport is nearby. Iron and steel form the chief industry; machinery and boots are made, and there is weaving, brewing, and sugar refining. Founded 1223 by Count Gunzelin of Wolfenbüttel, Peine belonged in turn to the Duchy of Brunswick, the Bishopric of Hildesheim, and the Kingdom of Hanover, passing to Prussia in 1866. (D. Wi.)

PEINE FORTE ET DURE, the term in English law for a torture inflicted on those who, arraigned of felony, refused to plead and stood silent; or who challenged more than 20 prospective jurors, which was deemed a contumacy equivalent to a refusal to plead. (Before he can be tried, a prisoner has to plead "guilty" or "not guilty.") By the Statute of Westminster, 1275, the *peine* was "strong and hard imprisonment," but in 1406 pressing to death by heavy weights was substituted. This was abolished in 1772, when "standing mute" was made equivalent to conviction. By an act of 1827 a plea of "not guilty" was to be entered against any prisoner refusing to plead, and that has remained the rule. *See* TORTURE.

PEIPING: *see* PEKING.

PEIPUS, LAKE (Estonian PEIPSI JÄRV; Russian CHUDSKOYE OZERO), in the U.S.S.R., lies between the Russian Soviet Federated Socialist Republic and the Estonian Soviet Socialist Republic. It is 48 ft. (15 m.) at its deepest, with an average of 25 ft. (7.5 m.), with mostly low, marshy shores; 96 km. (60 mi.) from north to south, and 50 km. (31 mi.) from east to west, excluding the smaller southerly extension of Lake Pskov. It is fed by the Velikaya River from the south, via Lakes Pskov and Teploye, and drains northward through the Narva River into the Gulf of Finland. With extensions its area is approximately 3,600 sq.km. (1,390 sq.mi.), but varies periodically when adjoining lowlands are flooded, highest water being in May or July–August. The north shore has sand dunes, while low cliffs reach the western shore. Water close to the shore usually freezes during December–April, the central surface for a shorter period. In summer, because of its shallowness, the water reaches a high temperature. The lake is suitable for navigation, and about 30 varieties of fish are caught, principally the European smelt. In April 1242 the Russians under Alexander Nevski defeated the Teutonic knights on the ice of Lake Peipus.

(J. P. Co.)

PEIRCE, CHARLES (SANTIAGO) SANDERS (1839–1914), U.S. logician and philosopher who originated American pragmatism and made important contributions in formal logic and in the logical analysis of mathematics. He was born in Cambridge, Mass., on Sept. 10, 1839, the son of the Harvard mathematician Benjamin Peirce (1809–1880), and prior to entering college in 1855 was educated largely by his father. Graduating from Harvard in 1859, he ranked, despite his brilliance, 79th in a class of 91. From 1861 to 1891 he was associated with the U.S. Coast and Geodetic Survey. He lectured at Harvard, Johns Hopkins University (1879–84), and elsewhere, for eight years altogether, but was not a popular teacher. His meticulous insistence upon clarity and precision and his technical vocabulary made his lectures difficult, and his academic career was also doubtlessly hampered by his distinctive, not to say eccentric, personality, and by domestic difficulties—in 1883 he divorced his first wife, from whom he had long been separated, and remarried shortly thereafter. His last years were spent in serious illness and in abject poverty relieved only by aid from such friends as William James—in whose

honour Peirce added "Santiago" (St. James") as his middle name. This was nevertheless a period of tireless writing and rewriting; in fact, some of his best work was done between 1906 and 1909. He died in Milford, Pa., on April 19, 1914.

Peirce's fundamental contributions in logic are summarized in LOGIC, HISTORY OF: *Modern Logic: Peirce.*

Although Kant had introduced the term *pragmatisch* almost a century earlier, Peirce is credited with creating the philosophy of American pragmatism and with first using the term in English in his paper "How to Make Our Ideas Clear" in the *Popular Science Monthly* for January 1878, where he states the pragmatic principle as follows: "Consider what effects, that conceivably might have practical bearings, we conceive the object of our conception to have. Then our conception of these effects is the whole of our conception of the object." Displeased with James's use of the term, in 1905 he invented "pragmaticism" for his own type of philosophy, saying that this word was "ugly enough to be safe" from misuse by the uninitiated. (For Peirce's formulations and his disagreements with James, *see,* further, PRAGMATISM.)

The specialized nature of Peirce's work made it difficult for him to find a publisher, and, except for professional papers, he published during his lifetime only *Photometric Researches* (1878), containing the results of his astronomical research at the Harvard Observatory. *Chance, Love and Logic* (1923) is a collection of his philosophical essays, edited by M. R. Cohen. *The Collected Papers of Charles Sanders Peirce* were edited by Charles Hartshorne and Paul Weiss (vol. 1–6, 1931–35), and Arthur W. Burks (vol. 7 and 8, 1958). (P. A. Sc.)

PEIRESC, NICOLAS CLAUDE FABRI DE (1580–1637), French antiquary, influential patron of learning, and discoverer of the Orion nebula (*q.v.*), was born at Beaugentier, Provence, on Dec. 1, 1580. Travels in Italy (1599–1602), studies at Padua, and acquaintance there with Galileo stimulated Peiresc's antiquarian interests. Returning to Aix, he took his legal degree (1604) and the next year became a senator in the Aix *parlement.* He was appointed lay abbot of the monastery of Guîtres in 1618. No published works by Peiresc are known, so that his name has tended to lapse into undeserved obscurity. Only records of his correspondence with such men as Peter Paul Rubens, and associations with British and French scholars indicate the catholicity of his interests. Peiresc was largely responsible for the publication of John Barclay's *Argenis* (1621) and he also encouraged Hugo Grotius' legal studies. One of the first to emphasize numismatics in historical research, an epigraphist, and collector of antiquities, Peiresc was first to verify William Harvey's discovery of the circulation of the blood and his work on optics was utilized by Sir Isaac Newton. He introduced into France such plants as ginger, jasmine, and the tulip. Peiresc died at Aix on June 24, 1637.

PEITHO, in Greek mythology, a goddess who is essentially a personification of the act of persuading (the name means "persuasion"). In literature she is often mentioned only figuratively, though as early as Hesiod she is curiously described as the daughter of Ocean. In both art and poetry she is introduced as an attendant on Aphrodite. She received worship at Athens, where her priestess had a seat in the theatre of Dionysus.

See Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft,* vol. 19, col. 194–217 (1937).
(H. W. Pa.)

PEKALONGAN, capital of the *kabupaten* (regency) of the same name in the province of Central Java, Indonesia, is situated on the northern coastal plain, 338 km. (210 mi.) ESE of Jakarta. Pop. (1961 census) 102,380, of whom many are Chinese or Arabs. There is a fort built in 1753, and a small harbour is used by coastal and fishing vessels. Pekalongan is the main trading and distributing centre for the area. It exports sugar, which is refined in the town, but by the mid-1960s the sugar industry had still not fully recovered from the devastation caused by fighting during and after World War II. Textiles form an important cottage industry and the town is one of the main centres of the batik industry (*see* TEXTILES: *Printed Textiles*), producing distinctive designs. The town lies on the main coastal road and railway linking Tjirebon and Semarang.

Pekalongan regency (pop. [1961] 851,224) has an area of 2,176 sq.mi. It was granted to the Dutch in 1746 by the Sultan of Surakarta. Bordering the Java Sea in the north, it includes the Kembang and Slamet mountains and part of the Dijeng Plateau in the south. The chief rivers are the Tjomal and the Pemali, flowing north. The river valleys and the coastal plain are very fertile, growing sugar, rice, kapok, cinchona trees, indigo, and maize (corn). Besides the capital, the chief towns are Tegal, Pemalang, and Tjomal, and Batang (Pa-an) is a fishing centre.

PEKIN, the seat of Tazewell County, Illinois, U.S., is an important port on the Illinois River, 10 mi. below Peoria in the central part of the state. A shipping centre for grain, cattle, and coal, Pekin is served by several railroads and is on the Lakes-to-Gulf Waterway. Its manufactures include corn products, alcohol, liquor, malt, steel tanks, barrels, burial vaults, and copper, brass, iron, and aluminum castings.

The first settler was Jacob Tharp in 1824; the town was laid out in 1829 and in 1830 was named Pekin, the "new Celestial City," by Mrs. Nathan Cromwell, wife of a founder. The dragon and other Chinese symbols are still used. An outpost for Indian warfare, its first schoolhouse (Snell School) was fortified during the Black Hawk War as Fort Doolittle. Incorporated as a city in 1849, Pekin for many years remained a rough river port, characterized by much violence. Abraham Lincoln argued cases in its old courthouse. Early settlers were Anglo-Americans from Virginia, Kentucky, and Tennessee and also from the northeast. German immigration began in the 1840s and grew after the Civil War; until World War I the German language was used in schools, churches and in business. Italians and Irish also settled there.

Good hunting and fishing in the vicinity make Pekin a favourite spot for sportsmen. Its large Mineral Springs Park has excellent swimming and other recreation facilities. Pekin's older streets are named Ann Eliza, Cynthiana, Henrietta, Matilda, etc., for friends of Mrs. Cromwell. For comparative population figures *see* table in ILLINOIS: *Population.* (M. Ws.)

PEKING (PEIPING), the capital of China, situated in Hopeh province. The name Peiping, which means "northern peace," was used in the Nationalist period, 1928–1949, while the nation's capital was at Nanking ("southern capital"). The name Peking (Peiching) meaning "northern capital," was used while the city was the capital of China, from 1421 to 1928, and again under the Communist regime after 1949. Peking is situated in lat. 39° 54′ N. and long. 116° 28′ E. at the northern apex of the alluvial north China plain. Its area is the point of convergence of routes from Manchuria via Shan-hai-kuan (the "gate between mountains and the sea"), and the easiest routes from the Mongolian plateau via the valley of the Yung-ting Ho and Nankow pass.

Only 35 mi. northeast of the city at its nearest point, the Great Wall of China, following the crests of the scarpland belt at an elevation of 4,000 ft., marks the historic frontier defense of the agricultural plain against the pastoral nomads of the interior plateaus. The narrow apex of the plain is thus the crucial region in the relations of China, Mongolia and Manchuria, and is historically the border zone between two strongly contrasted types of social organization.

History.—The earliest city of which there is authentic record was that of Ch'i, the capital of Yen, the most northerly of the feudal states which acknowledged the authority of the Chou dynasty in the twelfth century B.C. Thus early was the site of Peking within the Chinese culture area, but Yen was clearly a buffer state, intended to keep back the Tatar hordes, and is significantly mentioned in records of the 6th century B.C. as possessing great numbers of horses. Ch'ien Lung, the famous scholar-emperor of the Manchu dynasty, made extensive researches into the exact site of Ch'i and located it slightly to the north of the present city.

The city was destroyed by Shih Huang Ti, the "First Emperor" and founder of the Ch'in dynasty (221 B.C.), who unified China and completed the frontier defenses of the Great Wall. Yen was one of the districts which made up his empire. Under the Han dynasty a new city arose close to the site of Ch'i and was known first as Yen and later as Yu-chow. It remained a definitely Chinese city until the end of the Han dynasty, but in the ensuing period of anarchy and disintegration was for two centuries under Tatar control. The T'ang dynasty (7th to 10th centuries), like the Han, maintained the frontier defenses of the empire intact, and Yu-chow was the headquarters of a military governor. But early in the 10th century it came into the hands of the K'itans, one of the most famous of the Tatar groups prior to the rise of the Mongols, who successfully resisted the attempts of the Sung emperors to recover it for China. The K'itans under the Liao dynasty (sometimes called the Iron dynasty) rechristened the city Nanching, signifying southern capital, and later (986) rebuilt it on imperial lines with walls said to have been 13 miles in length and 30 feet high.

From early in the 11th century it was known as Yenching but the K'itans of the Iron dynasty continued to hold it until 1122 when it was captured by the chief of the Tatars of the Golden Horde from the northern steppes of Manchuria, who greatly enlarged and beautified it and made it one of the three capitals of his large empire, that of the Kin or Chin (Gold) dynasty. The other two capitals were Pien-ching (now Kai-feng) in Honan and Shen-yang (Mukden) in the north, so the future Peking was known at this period as Chung-tu or the "middle capital." This phase lasted until early in the 13th century when the greatest of all the steppeland powers arose, the Mongol empire.

The City Under Kublai Khan.—Kublai Khan took the decisive step of making it the metropolitan city of the immense Mongol empire, which now stretched from the Pacific to beyond the Black sea. But although this was the technical status of the city after Kublai had moved his headquarters there from Karakorum in 1267, it was as the new capital of China that the choice was of the greatest ultimate significance. Kublai was indeed the "Great Khan who ruled in China" but his descendants were primarily emperors of China.

Under Kublai the city was once again rebuilt and on a more magnificent scale than ever before. It was named Khanbaliq, "city of the Khan," but the Chinese knew it as Ta-tu, "great capital." Through the reports of Marco Polo, who visited China at that time, Khanbaliq became known in medieval Europe as Cambaluc. This was often, as by Longfellow, inaccurately spelled Cambalu. Marco Polo described the magnificence of the capital in glowing terms. Cambaluc was laid out on a rectangular plan and had a circuit of 24 mi. Its walls, 50 ft. high and on top 15 ft. thick, were each pierced by three gates, the roadways connecting them running straight across the city.

Marco Polo was followed by the Pope's envoy, Giovanni di Monte Corvino, who was well received by Kublai and made archbishop of Khanbaliq in 1307.

The Ming and Manchu Dynasties.—Later under the Ming and early Manchu dynasties the Jesuits were in favour at the capital, and were encouraged to practise western mathematics and astronomy. The communications of Khanbaliq with the rest of China were actively developed by the construction of radial roads on which well-organized courier services were maintained, and by extending the Grand Canal from the Yellow river to Tientsin and connecting it by the Pai Ho and a small canal, the capital was brought into direct water-communication with the lower Yangtze valley.

Khanbaliq continued to be the capital of China throughout the Yuan dynasty but the city temporarily lost its imperial status when in 1368 Chu Yuan-chang (Hung Wu) headed the successful revolt against the Mongols and established the native Ming dynasty. After being under the control of foreign steppeland powers for about 450 years the region was once again under direct Chinese rule and Khanbaliq, now known as Peiping, served, as in the days of the Han and T'ang dynasties, the function of a border garrison town, subordinate to the capital city of Nanking. This phase lasted until 1421, when the third Ming emperor, Yung Lo, transferred his court to the north and Peiping was given the name of Peking.

The reason for this decisive step was undoubtedly strategic, for the Mongols were still troublesome and the Manchurian tribes were becoming increasingly strong and restless. Peking was the only frontier capital which could guard both the vulnerable flanks. The menace from the north, increased by internal revolts, culminated in the Manchu conquest of 1644 and China once again came under Tatar domination. The new Manchu (or Ch'ing) dynasty transferred their court from Mukden to Peking and administered their newly won empire from a capital which, while it lay within the Chinese culture area, was in close contact with their own recruiting ground.

The Modern Period.—Two and a half centuries later the rule of the decadent Manchus was ended by the revolution of 1911 and the imperial office was abolished. Peking continued to function as the capital of the new republic. But the disintegrating effects of the civil war and the rise of the nationalist movement, focused in the south, meant that the rule of the Peking government was increasingly ineffective and nominal. The final northward advance of the nationalist armies in the spring of 1928 was quickly followed by the proclamation of Nanking as the capital of the new China and by autumn 1928 the northern city had lost its metropolitan status and was known once more as Peiping, the name which it bore under the early Ming emperors. So, too, the province, in the centre of which it lies, reverted to the ancient name of Hopeh ("north of the river," *i.e.*, the Yellow river) in place of Chihli ("direct rule").

After the Tangku truce of 1933 which ended the Manchurian invasion, the Japanese endeavoured to separate Peiping and north China from the rest of China. The Chinese government was forced to approve the establishment in Peiping of a Hopeh-Chahar politi-

cal council under the chairmanship of Gen. Sung Chih-yuan, commander of the 29th army. By the Ho-Umetsu agreement of 1935 all Chinese troops and Kuomintang organizations were excluded from north China. In spite of strong Japanese pressure, Sung remained loyal to the Chinese government. On July 7, 1937, the Japanese during maneuvers attacked the Marco Polo bridge (Lu-kou-ch'iao) across the Yung-ting Ho southwest of Peiping to sever the last railroad link with the rest of China. The Chinese garrison resisted and thus began the war with Japan which merged in 1941 with World War II. The city was taken by the Japanese in July 1937 and remained occupied until the end of World War II in 1945, when it reverted to Nationalist control. In 1949, Peiping fell to the Chinese Communists, who made it once more the capital of China under its historic name of Peking. (*See* also CHINA: *History*.)

Description.—Peking consists essentially of two walled cities, the northern Inner city and the southern Outer city. The Inner city, also known as the Tatar city, lies approximately on the site of Khanbaliq of the Mongol dynasty. It is in the form of a square with walls nearly 15 mi. in length.

The Outer city, also known as the Chinese city, was added during the reign of the emperor Chia Ching (1522–66) of the Ming dynasty. It is in the form of an oblong adjoining the Inner city, with walls 14 mi. in length, including 4 mi. of the southern wall of the Inner city.

Within the Inner city was the Imperial city, also in the form of a square and with red-plastered walls six and one-half miles in length, of which only the southern wall and a part of the western wall remain. And within the Imperial city was the moated Forbidden city, with walls two and one-quarter miles long, plastered with a violet-coloured mortar, whence comes the popular name of the Purple city. The Forbidden city contained the Imperial palaces, which have been converted into a museum. The palaces, symmetrically arranged, consist of outer throne halls, an inner court, and the palace buildings.

The entrance to the Forbidden city is through the Wu Men (Meridian gate). Ancient works of art are found in T'ai-ho-tien (Hall of Supreme Harmony) and Pao-ho-tien (Hall of Preserving Harmony), two of the outer throne halls. Works of art of different dynasties, ranging from the Shang (1600–1100 B.C.) to the Ming, are found in halls on the east side of the inner court. In halls on the west side of the inner court are works of art of the Manchu dynasty.

In side halls on both sides of the courtyard in front of the Wu Men is the historical museum, exhibiting historical objects from primitive times, through the Hsia (2100–1600 B.C.), Shang and Chou dynasties to the Sui (A.D. 581–618) and T'ang dynasties. In the main hall above the Wu Men are objects of China's modern history after the Opium war of 1840.

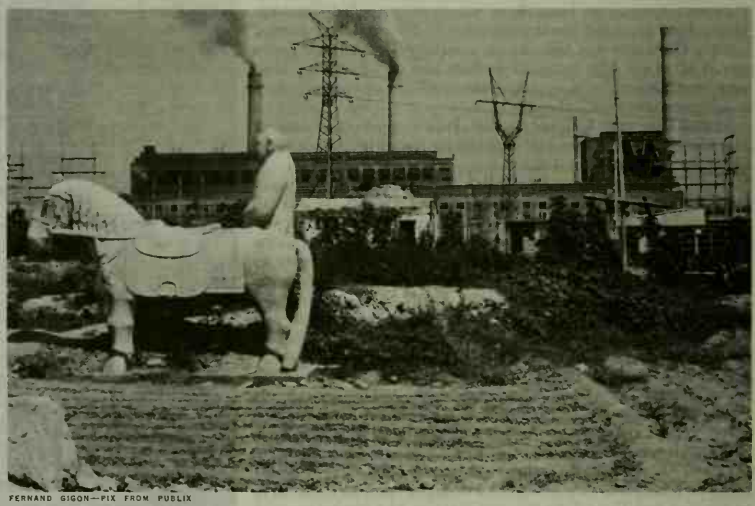
South of the Palace museum, the former imperial roadway separates two parks that have been converted into public recreation areas under the Communist regime. On the west side is Sun Yat-sen park, surrounding the former Altar of Land and Grain, and on the east side is the Working People's Palace of Culture, which was the Imperial Ancestral temple, in which tablets of emperors were displayed and worshiped.

Adjoining the parks on the south is part of the remaining southern wall of the former Imperial city. The wall is pierced by T'ien-an Men (Gate of Heavenly Peace), on which China's Communist leaders gather on ceremonial occasions to review military and civilian parades in the square adjoining the gate.

Adjoining the Forbidden city on the east, in the southeast quadrant of the Inner city, is the old legation quarter, where foreign representatives had their residences. The legation quarter contains many hotels, department stores, theatres and cinemas.

In the northeast quadrant of the Inner city stand some of the most historic buildings of China, including the Lama temple and the simple but beautiful Temple of Confucius. Nearby is the Bell tower, where the curfew was sounded nightly in imperial times.

Extending in an irregular chain from the north wall of the Inner city are six artificial lakes supplied from a moat outside the walls of the city. The shores of Pei Hai (North lake), just



FERNAND GIGON—PIX FROM PUBLIX

MODERN ELECTRICAL PLANT OUTSIDE PEKING. IN CONTRAST IS THE 18TH-CENTURY STATUARY IN THE FOREGROUND, A MONUMENT ERECTED UNDER EMPEROR CH'IEN-LUNG, CH'ING DYNASTY. AT THE BASE OF THE MONUMENT IS A VEGETABLE GARDEN OF THE WORKERS AT THE PLANT

northwest of the Palace museum, have been converted into a park. The National library stands on the southwest shore. Grouped around Chung Hai (Middle lake) and Nan Hai (South lake), just west of the Palace muscum, are the government buildings of the Chinese Communist regime.

The northern part of the Outer city is a busy commercial and shopping area adjoining the city's main railroad terminal at the Ch'ien Men, the main gate connecting the Inner city and the Outer city. In the southern portion are the grounds of the Temple of Heaven and of the Temple of Agriculture.

In modern times, and especially after 1949, Peking has expanded far beyond the two walled cities that constitute its core. Residential suburbs and educational centres have risen to the west and northwest. Extending along a road going northwest to the former Summer palace and its lakes and parks are many of China's important universities: Peking (former Yenching university), Tsinghua university, People's university and many specialized institutions of higher learning, such as the Central Institute of Nationalities, and schools in the fields of iron and steel, geology, aeronautics and other engineering disciplines. Outside the northwestern gate, Hsi-chih Men, are the city's zoo and permanent exhibition grounds.

Industry.—While the city's educational and cultural institutions are being expanded largely in the western and northwestern suburbs, Peking's growing industries are concentrated east of the city. In connection with the city's growth as China's political and cultural centre under the Communist regime, attention was also given to the expansion of industry.

Manufacturing was traditionally restricted to light industry (flour mills, textiles, garments). After 1949, several heavy industrial enterprises were added, including a machine-tool plant, a printing machinery factory and a synthetic fibres mill. An auto parts factory was expanded into a small automobile plant, and a farm-machine factory was converted into a tractor plant. Other industrial suburbs, southwest of the city, include Feng-t'ai, with railroad marshalling yards, bridge-construction, concrete railroad ties and asbestos-pipe factories, and Ch'ang-hsin-tien, with locomotive and rolling-stock shops.

The iron and steel plant of Shih-ching-shan is situated on the Yung-ting Ho, 14 mi. west of the city centre. This plant, first opened in 1920, was completed in 1937 and produced 80,000 tons of pig iron at its peak under Japanese rule. The plant was greatly expanded by the Communists, and annual production increased to more than five times its previous capacity. Beyond Shih-ching-shan, at the end of a rail spur, 20 mi. west of the city centre, are the coal mines of Men-t'ou-kou.

Peking is a transportation hub with rail connections to Hankow, Canton, Kalgan, Pao-t'ou, Tientsin, Mukden, Tungchow and Ch'eng Te. It is also linked to the Soviet Union via Manchuria and via Outer Mongolia.

Administration.—Under the Nationalist regime, Peking's municipal area covered more than 300 sq.mi. Under the Communists, the city limits were greatly expanded. As a result of annexations in 1953, the municipal district was extended to the Great Wall, 35 mi. from the city centre.

Within this expanded area of 1,750 sq.mi., the 1953 census reported a population of 2,768,149, of whom about 830,000 lived in the walled Inner city, 220,000 in the Outer city, and 1,700,000 in suburbs outside the walls. By the early 1960s, the population of Peking was estimated to be more than 4,000,000 as a result of the in-migration of people attracted by the city's growing importance as the nation's political, educational and economic centre. In March 1958, a second expansion of the municipal area took place, nearly doubling its territory from 1,750 sq.mi. to 3,386 sq.mi. This time Peking absorbed the towns of T'ung-chou (Tungchow) and Shun-yi on the east, Ta-hsing on the southeast, and Fang-shan and Liang-hsiang on the southwest. The new municipal area had an estimated population of 6,800,000, of whom more than 2,000,000 were rural farmers.

Peking is administered directly by the central government, and is outside the jurisdiction of Hopeh province. The municipal district itself is divided into five suburban districts (*hsien*) and eight boroughs (*ch'u*). The latter are Hsi-ch'eng and Tung-ch'eng in the Inner city; Ch'ung-wen and Hsuan-wu in the Outer city; and the suburban *ch'u* of Hai-tien, with the city's educational institutions; Men-t'ou-kou, with the coal mines; Feng-t'ai and Ch'ao-yang.

The *hsien* consist of Ch'ang-p'ing with the Ming tombs north of the city, Fang-shan where the remains of Peking Man were found southwest of the city, Ta-hsing, T'ung and Shun-yi.

PELAGIA, SAINT (?–*c.* 311), a 15-year-old Christian girl of Antioch who, probably during Diocletian's persecution, threw herself from a housetop to avoid outrage, and died on the spot. Her feast day is June 9.

The memory of this historical Pelagia helped to give rise to two legends of fictitious Pelagias: namely, Pelagia the Penitent (also called Margarito), a prostitute of Antioch who experienced sudden conversion and lived the rest of her days in a cave at Jerusalem, disguised as a man; and Pelagia of Tarsus, who refused to marry the emperor Diocletian and was punished by being roasted to death. Both are named in some calendars.

The origin of the first of these two legends was the repentance of a notorious Antiochene woman, of whom John Chrysostom speaks without mentioning her name.

Both legends are connected with that of St. Margaret (*q.v.*).

See H. Delehaye, *The Legends of the Saints* (1907). (D. Ar.)

PELAGIUS, the name of two popes.

Pelagius I (d. 561), pope from 556 to 561, was a noble born at Rome, date unknown. Under Popes Agapetus I, Silverius and Vigilius his ecclesiastical roles were highly important. He was elected to succeed Vigilius in 555 and consecrated on April 16, 556. At first opposed to Vigilius' condemnation of the "Three Chapters" (554; *see* Papacy) Pelagius upheld it as pope, winning thereby hostility in the west, especially in northern Italy, where long schism developed. He died on March 4, 561.

Pelagius II (d. 590), pope from 579 to 590, was born at Rome, date unknown, of Gothic descent. During his pontificate, which began on Nov. 26, 579, Lombard barbarians pressed more deeply into Italy. Schism arising out of the "Three Chapters" controversy resisted his conciliatory efforts in northern Italy. Pelagius protested when the bishop of Constantinople assumed the title "ecumenical patriarch." He died on Feb. 7, 590.

(Jn. F. B.)

PELAGIUS (fl. 405–418), proponent of a doctrine, condemned as heresy by the Christian Church, which was thought to minimize the role of divine grace in man's salvation. Pelagianism was a cause of discord in the church for more than a century.

Little is known about the circumstances of Pelagius' early life. He was born in Britain, and attempts to argue that he was of Irish origin and to see his name as a hellenized form of the Irish *Muirchu* ("son of the sea") or the Welsh *Morgan* have no foundation. He was a layman, often styled a monk by his contemporaries, well educated in the Latin classics, and familiar with the Bible, the Latin Fathers, and a certain amount of Greek theology in translation. According to St. Augustine, he long resided at Rome, and the familiarity with legal matters displayed in his writings and his taste for clear-cut definition suggest that he may originally have come there as a law student, abandoning his secular studies after his baptism, perhaps in the last years of the pontificate of Pope Damasus (d. 384). During the next two decades, Pelagius lived at Rome and wrote his most important works, including a treatise on the Trinity, now lost, and his commentary on the Epistles of St. Paul.

In his writings, he attacked the Arians and the Manichaeans, asserting against the former Christ's full divinity and against the latter his full humanity (*see* Arianism; Manichaeism). Pelagius' anti-Manichaean polemic led him to lay stress upon the essential goodness of human nature and the freedom of the human will, and this dogmatic emphasis was intensified by a desire to recall his contemporaries to stricter observance of Christian conduct. His outlook is well illustrated by the famous episode which occurred about 405, when he rebuked a bishop who quoted St. Augustine's famous prayer from the *Confessions:* "Give what thou commandest

and command what thou wilt," which seemed to Pelagius to provide an excuse for indolence and lethargy (*see* Augustine, *De dono perseverantiae*, xx, 53). Clearly, to some persons, such an outburst could imply a denial of the need for grace, but Pelagius' reforming views found much support at Rome. His disciples included Celestius and Julian, the future bishop of Eclanum in southern Italy, and he had many followers among the pious ladies of the Roman aristocracy.

About 409, when the Goths menaced Rome, Pelagius and Celestius removed, first to Sicily and thence to North Africa. After the Conference of Carthage of 411, Pelagius departed to Palestine, leaving Celestius behind. The latter appears to have obtained considerable influence among the Carthaginian Christians, when he was charged with heresy by Paulinus, a deacon of Milan then visiting Africa, and accused of denying that Adam's sin had any effect upon his descendants, so that infants are born in the condition of Adam before the Fall. Celestius was tried before Aurelius, bishop of Carthage, and excommunicated. He considered appealing to Rome, decided otherwise, and left for Ephesus.

Meanwhile Pelagius had arrived at Jerusalem, where he found many friends and one bitter enemy, St. Jerome, then living at Bethlehem. The writings of Pelagius and the propaganda of Celestius were having their effect and making many converts. St. Augustine saw in Pelagius' views a denial of the need for prevenient grace (*i.e.*, grace that is antecedent to every good action) and from 412 onward was constantly writing and preaching against Pelagian doctrines, although he spoke of Pelagius personally with respect (*see* Augustine, Saint, of Hippo). In 415 the Spanish priest Paulus Orosius (*q.v.*) arrived at Bethlehem, bearing letters from Augustine to Jerome. Orosius accused Pelagius of heresy at a diocesan synod held before Bishop John of Jerusalem, but failed to secure Pelagius' condemnation. The matter was referred to a provincial synod, held at Diospolis (Lydda) before Eulogius of Caesarea, the primate of Palestine, on Dec. 20, 415. Here Pelagius gave satisfactory (his enemies thought hypocritical) answers to the charges brought against him and was exonerated. He was, however, subsequently discredited by an assault by his sympathizers on St. Jerome's monastery at Bethlehem and shortly afterward (Jan. 27, 417) was excommunicated by Pope Innocent I. The force behind this excommunication was an appeal from the African episcopate to the pope in the second half of 416 inspired by reports from Orosius of the events in Palestine. Innocent died on March 12, 417, and was succeeded by Pope Zosimus, who showed himself more favourable to the Pelagians than his predecessor had.

Zosimus was visited by Celestius, was impressed by him, and, after receiving a profession of faith from Pelagius, sent a strongly worded letter to the African bishops on Sept. 21, 417, accusing them of having acted precipitately in condemning Pelagius and Celestius. The Africans, however, maintained that the case had already been settled by the judgment of Innocent. Outbreaks of violence by the Pelagian party at Rome stirred the imperial authorities to action, and on April 30, 418, the emperor Honorius issued a rescript condemning Pelagianism and exiling Pelagius (who was assumed to be at Rome) and Celestius from Italy. Next day, May 1, 418, an African council held at Carthage passed a series of nine canons against Pelagianism. Meanwhile Zosimus, who had already begun to entertain doubts about the Pelagian case, now read Pelagius' commentary on Romans. He was shocked by its doctrine and commanded Celestius to appear before him for examination. Celestius ignored the summons and fled from Rome, thereby appearing self-condemned. Zosimus then issued a lengthy document, which survives only in fragments, the *Epistola tractoria*, in which he excommunicated Pelagius and Celestius and condemned their doctrine. Subscription to the *Tractoria* was enforced in Italy by imperial authority, but 18 bishops, including Julian of Eclanum, refused to sign. Julian demanded a general council to discuss the matter, but his appeal was rejected and he was deposed. Pelagius, horrified by his excommunication, now affirmed that grace was necessary, not only for every hour or moment but for each individual action of our lives. His confession was not accepted. He was expelled from Jerusalem and departed, probably for Egypt. His subsequent fate is unknown.

The controversy, however, was far from ended. Julian of Eclanum continued to assert the Pelagian view and engaged Augustine in literary polemic until the latter's death in 430. Julian himself was finally condemned, with Celestius and the rest of the Pelagian party, at the Council of Ephesus in 431. Meanwhile the vehemence with which Augustine defended his own doctrine of original sin and predestination aroused opposition among many Christians who had no sympathy with Pelagius—the so-called Semi-Pelagians of southern Gaul who might better perhaps be called Anti-Augustinians. These included the saintly John Cassian, abbot of Saint-Victor at Marseilles (*see* Cassianus, Johannes), and Euladius, bishop of Arles. Augustinian doctrine was defended in Gaul by St. Prosper (*q.v.*) of Aquitaine, and the dispute, which was very bitter, was not finally settled until nearly a century after St. Augustine's death, at the Council of Orange of 529. (*See* Semi-Pelagianism.)

The theology of Pelagius was not, as the scholar Adolf von Harnack held, basically godless, and its affinities with Stoicism have been exaggerated. Pelagius never crudely affirmed that man could be good without God. His thought was inspired by the Bible, and he stood in a direct line from earlier theological writers, notably Ambrosiaster and Origen, whom he knew from the translation of Rufinus. He never doubted that his system was anything other than Christian orthodoxy. He did not seek publicity and undoubtedly suffered through the excesses of his disciples. The weakness of his position lay precisely in the zeal with which he sought to refute Manichaean determinism and to rebuke the laxity of professing Christians. Pelagius admitted divine grace in man's natural endowments; in the revelation of the Old and New Testaments; and, above all, in the remission of sins in Christian baptism, whose necessity he affirmed for every age and condition of man, while rejecting the Augustinian view of the physical transmission of Adam's sin to his descendants. His great defect lay in an inadequate comprehension of the weakening of human nature resulting from the Fall and of the complexity of the numerous conflicting impulses which constitute the human will. It was here that Augustine, despite some unlovely harshness in his doctrine, had a better understanding of sin and grace than Pelagius.

PELARGONIUM, a genus of plants belonging to the geranium family (Geraniaceae, *q.v.*) and including most of the cultivated ornamentals known as "geraniums." *See* Geranium.

PELASGIANS, an ancient people of the Aegean, equated by classical Greek ethnological theory with the pre-Hellenic inhabitants generally (*see* Leleges). In the *Iliad* of Homer they are mentioned among Trojan allies (ii, 840–843), standing in the list, which is generally in geographical order, between Thracians and inhabitants of Hellespontine towns. Their "far-off" city of Larisa (*Iliad*, xvii, 301) is therefore probably imagined to be in southeastern Thrace and is not identical with any of the numerous places called Larisa in historic times. In northern Greece they seem already to be remembered as displaced by Achaeans; Achilles' Myrmidons inhabit "Pelasgian Argos" (*Iliad*, ii, 691 ff.; *see* Argos), and Achilles prays to the "Pelasgian Zeus" of northwestern Dodona (*q.v.*; *Iliad*, xvi, 223). In the *Odyssey* (xix, 177) they are mentioned among the many peoples, native and immigrant, of Crete. In classical times Herodotus (i, 57) mentions them as "having occupied Plakia and Skylake" on the Sea of Marmara (towns identified by later geographers on its south coast, east of Cyzicus) and as "holding the city of Kreston, beyond the Tyrsenoi." This is puzzling, since Tyrsenoi (Tyrrhenians) elsewhere in Herodotus means the Etruscans of Italy; but Thucydides (iv, 109, 4) seems to identify the "Krestonians" with the "bilingual barbarians" (speakers of Greek and a native vernacular) of a group of settle-

ments, mostly with Greek names, on the Mt. Athos peninsula. Herodotus adds the important observation that the two groups spoke a common language, which was not Greek. They may well, therefore, have been remnants of a people once more widely spread but in his time elsewhere overlaid by Greeks or Thracians.

The "Pelasgian Theory."—But Herodotus quotes these details in connection with the above-mentioned theory, which identified the Pelasgians with the pre-Hellenic (modern theory would say "pre-Indo-European") population of Greece in general (Herodotus, i, 56). This theory was correct in distinguishing two chief strains in the Greek population, one immigrant, the bringers of the Indo-European Greek language, and the other aboriginal, Mediterranean as we should say, or old Aegean; but Herodotus oversimplifies in identifying the former exclusively with the Dorians (*q.v.*), whose invasion of southern Greece was remembered as an epoch-making event. Greek tradition, its oldest surviving documents being the Homeric epics, preserved no clear memory of the ages before the Trojan War, nor of the earlier migrations which must, it would seem, have brought in the pre-Dorian Greek dialects (*see* GREECE: *Ancient History*). Herodotus, therefore, had difficulties in placing the aboriginal ("autochthonous") Athenians and other speakers of kindred dialects (Ionians; *q.v.*) in terms of his theory, and supposes them to be "Pelasgians" who had learned their Greek from contact with the Hellenes proper. The name Pelasgians thus acquired its later literary use as an equivalent for "aborigines," a usage no more historically justified than that of "Iberians" for early inhabitants of Britain. Neither the usage nor the theory was first invented by Herodotus; the eponymous hero Pelasgus was claimed as their ancestor by the mountaineers of Arcadia, equally "autochthonous" and speaking an archaic Greek dialect, a claim traceable as early as the Ionian epic poet Asius (7th century?), quoted by Pausanias (viii, 1); and Aeschylus in *The Suppliants* (250 ff.) makes Pelasgus a king of primeval Argos, with an empire stretching to the Strymon (thus taking in the Mt. Athos peninsula) and to "the mountains of Dodona."

Whether any ancient people actually called themselves Pelasgians, otherwise than in the terms of this literary convention, is uncertain; it may, like "Phoenicians," have been originally a name bestowed by the Greeks; for the suggested derivation from *pelagos*, "sea," by way of a hypothetical original form *Pelag-skoi*, is thought by philologists to be linguistically possible. And such a north Aegean "sea people" could possibly have been connected with the Tyrrhenians or Etruscans, that element in the population of early historic Etruria which, according to a persistent tradition, had come by sea from the East. Some elements in Etruscan culture do suggest Eastern affinities (*see* ETRUSCANS); and possible connecting links may be found in the archaeology of Lemnos, an island which also had, until the Athenian conquest about 500 B.C., a non-Greek population called by Herodotus (iv, 145; vi, 137) Pelasgians.

(A. R. BU.)

PELAVICINO (PALLAVICINO), **OBERTO** (1197–1269), Lombard statesman powerful in northern Italy, was born at Polesine, near Cremona, of a feudal family with lands in the territories of Parma, Piacenza, and Cremona. The Holy Roman emperor Frederick II (*q.v.*) appointed him vicar of the Lunigiana and Pontremoli in 1239; vicar-general of the Lunigiana, Versilia, and Garfagnana from 1243 to 1245; *podestà* of Reggio (Nell' Emilia) in 1246; and, after the capture of King Enzio by the Bolognese in 1249, vicar-general "from Pavia downward" (*i.e.*, southward to Tuscany).

Elected *podestà* of Cremona in 1249, Oberto used his local influence after Frederick's death (1250) to build up an extensive dominion in Lombardy. Appointed vicar-general in Lombardy for King Conrad IV (1253), he could by October 1254 style himself "lord for life of Cremona, Piacenza, Pavia, and Vercelli." In 1259, having defeated his former ally Ezzelino (*q.v.*) da Romano, he also acquired Brescia; Milan elected him as its lord for five years.

Milan's defection in 1264 marked the beginning of Oberto's decline; his power collapsed when, after the victory of Charles of Anjou in 1266, the Guelph party prevailed in Lombardy. Oberto died at Pontremoli on May 8, 1269.

See Z. Schiffer, *Markgraf Hubert Pallavicini* (1910). (N. R.)

PELAYO (d. ?737), traditionally recognized as the first of the Asturian kings, ruled from *c.* 718 to *c.* 737. His existence is attested by Arabic as well as Christian chroniclers but, since the earliest accounts of him belong to the late 9th century, his historical personality is overshadowed by legend. As far as can be ascertained he was a page, or possibly a member of the royal bodyguard, of the Visigothic king Roderick, and may have been of royal blood. He survived the defeat (711) of the Visigoths by the Moors at the Battle of Guadalete near Medina Sidonia and reached his native Asturias, where he led a revolt of Asturians and Visigothic refugees against the Moorish governor Munuza. He was captured and sent to Córdoba as a hostage, but escaped (717) and again assumed leadership of the Asturian rebellion. The rebels, though driven into the uplands of the Picos de Europa, were able to survive massive attacks by Moorish armies, especially at the Battle of Monte Auseba, and, eventually, Pelayo—accepted as their ruler—was able to set up a tiny kingdom with its capital at Cangas de Onís. The stories and relics of Pelayo associated with the nearby shrine of Covadonga belong to legend rather than to fact; it was, however, in this legendary guise that he became an important symbol of Christian resistance in medieval Spanish history.

(P. E. R.)

PELECYPODA, a name, synonymous with Lamellibranchia, for the bivalve (*q.v.*) mollusks.

PELEUS, in Greek mythology king of the Myrmidons (*q.v.*) of Phthia in Thessaly, and most famous as the husband of Thetis and father of Achilles, whom he survived. When he and his brother Telamon were banished from their father Aeacus' kingdom of Aegina because they had conspired to murder their half brother Phocus (*q.v.*), he went to Phthia to be purified by his uncle, King Eurytion. There he married Eurytion's daughter Antigone and received a third of Eurytion's kingdom. Later he took part in the voyage of the Argonauts and the Calydonian boar hunt, during which he accidentally killed Eurytion. He then went to Iolcus to be purified by King Acastus, whose wife, Astydameia, made advances to him. When he refused her she told Antigone he wanted to marry her daughter, so Antigone hanged herself. Astydameia further accused Peleus to Acastus of attempting to seduce her. Acastus thereupon tried to betray Peleus unarmed to the Centaurs, but the gods rescued him. He won Thetis (*q.v.*) by capture and all the gods came to the wedding (*see* ERIS), but after bearing Achilles (*q.v.*) to him she returned to the depths of the sea. In the end, however, she fetched him to dwell with her.

See A. Lesky in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, col. 271–308 (1937). (H. W. PA.)

PELHAM, the name of an English family, derived from Pelham in northeastern Hertfordshire. The family dignities have included the baronies of Pelham of Laughton (1706–68) and Pelham of Stanmer (from 1762), the earldoms of Clare (1714–68), Chichester (from 1801), and Yarborough (from 1837), and the dukedoms of Newcastle upon Tyne (1715–68) and Newcastle-under-Lyme (from 1756).

In the late 13th century a certain WALTER DE PELHAM acquired lands in Sussex, where in future the family's great estates were held. SIR JOHN PELHAM (*c.* 1355–1429) was appointed constable of Pevensey by Henry IV and was given the rape of Pevensey, a feudal castlery or demesne which ran inland across Ashdown Forest as far as East Grinstead. His son SIR JOHN II (*c.* 1400–71) was chamberlain to Catherine, queen of Henry V. The direct male line was continued through THOMAS (d. *c.* 1517), third son of John II. His son SIR WILLIAM (1486–1538), was twice married. By his first wife Mary, daughter of Sir Richard Carew, he was ancestor of the Barons Pelham of Laughton, of the dukes of Newcastle, the earls of Chichester, and of the Pelhams of Catsfield Place, Sussex. By his second wife Mary, daughter of William, Lord Sandys of the Vine, Sir William Pelham was ancestor of the Pelhams of Brocklesby, Lincolnshire, who became earls of Yarborough. The 6th earl of Yarborough is MARCUS HERBERT PELHAM (1893–).

Sir Thomas Pelham (d. 1624), grandson of Sir William and of Mary Carew, was created a baronet in 1611. His great-grandson, Sir Thomas (d. 1712), the 4th baronet, was created Baron Pelham of Laughton in 1706. The 1st baron's two sons, Thomas Pelham Holles (1693–1768), duke of Newcastle upon Tyne (*see* Newcastle, Dukes of), and Henry Pelham (*q.v.*; 1696–1754), both held the office of prime minister. When Newcastle died without issue, his dukedom of Newcastle upon Tyne, his earldom of Clare, and the barony of Pelham of Laughton became extinct. But the dukedom of Newcastle-under-Lyme had been granted him in 1756, with special remainder to the son of his sister Lucy, Henry Fiennes Clinton, afterward Pelham-Clinton (1720–94), 9th earl of Lincoln. From him is descended the present duke, Henry Edward Hugh Pelham-Clinton-Hope (1907–). The barony of Pelham of Stanmer, conferred on the 1st duke in 1762, had remainder to his cousin Thomas Pelham (d. 1805), great-nephew of the 1st Baron Pelham of Laughton.

Anthony Pelham (d. 1566), second son of Thomas (d. *c.* 1517), was ancestor of the Pelhams of New England and of the Pelhams of Compton Valence in Dorset. Anthony's son Herbert (*c.* 1546–1620) was twice married. His first wife was Katherine Thatcher and among their grandchildren were Herbert III (*c.* 1600–74), treasurer of Harvard College, and Penelope (1619–1702), who married Richard Bellingham (1592–1672), governor of Massachusetts. Herbert III's daughter Penelope married Josiah Winslow, governor of Plymouth colony from 1673 to 1680. As his second wife, Herbert (*c.* 1546–1620) married Elizabeth West of Compton Valence, where their issue subsequently resided.

See M. A. Lower, *Historical Notices of the Pelham Family* (1873); E. G. Pelham and D. McLean, *Some Early Pelhams* (1931).

PELHAM, HENRY (1696–1754), prime minister of England from 1743 to 1754, was the son of Thomas, 1st Lord Pelham, and Lady Grace Holles, daughter of the 3rd earl of Clare. He was educated at Westminster School and Hart Hall (later Hertford College), Oxford, and then served briefly in the Army, taking part in the defeat of the Jacobites at Preston (November 1715). Pelham was elected to Parliament for Seaford in 1717 and then for the county of Sussex in 1722, a seat he held for the remainder of his life. In Parliament he was a consistent supporter of Robert Walpole and through this devotion and his family connections soon gained office. Starting as a lord of the treasury in 1721, he became secretary for war (1724) and paymaster to the forces in 1730. He supported Walpole during the excise crisis in 1733 and was one of his staunchest defenders in 1742 after Walpole had lost office and was threatened with impeachment.

After a year's uneasy combination of Whig factions under Lord Wilmington, Pelham became prime minister and chancellor of the exchequer in 1743. He managed to survive two initial threats of disruption and led a relatively stable Whig ministry until his death in 1754. Much of his success depended on the brilliant borough-mongering and parliamentary personnel management of his brother Thomas, the duke of Newcastle (*see* Newcastle, Dukes of). Relations between the brothers, however, were at times strained, and there were several open disputes. Pelham was able to get rid of John Carteret, earl Granville, in 1744, a favourite of George II, who advocated a more vigorous prosecution of the War of the Austrian Succession. The administration was remodeled and became known as the "Broadbottom Administration" since it had given office to groups of dissident Whigs. By a mass resignation of the cabinet in 1746 (the first recorded example in English history) Pelham forced George II to abandon Lord Bath and Granville as leaders of an alternative ministry and even accept people in office like William Pitt, who were personally obnoxious to the king. He concluded the treaty of Aix-la-Chapelle in 1748 and made serious attempts to reduce the national debt and remodel the finances. He died in London on March 6, 1754. *See* also English History; *The First Hanoverians (1714–60)*.

PELIAS, in Greek mythology, a king of Thessaly, who imposed on his step-nephew Jason (*q.v.*) the task of bearing off the golden fleece (*see* Argonauts). According to Homer, Pelias and Neleus (*q.v.*) were twin sons of Tyro by Poseidon, who came to her disguised as the river-god Enipeus, whom she loved; Tyro afterward became the wife of Cretheus, to whom she bore Aeson, Jason's father. Later legend relates that on Jason's return with the fleece his wife, Medea (*q.v.*), the enchantress, persuaded Pelias' daughters, except for Alcestis, to cut up and boil their father in the mistaken belief that he would thereby recover his youth.

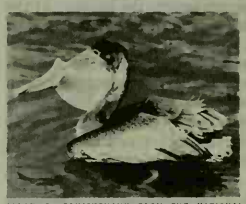
PELICAN, the large water bird famous for its enormous beak, from the lower half of which is suspended a somewhat elastic pouch. About six species of *Pelecanus* comprise the family Pelecanidae, related to the cormorants and gannets. All pelicans breed in colonies; some nest on the ground on islands, others build nests of sticks in bushes or trees. They live on fish which are caught, but not stored, in the pouch. The pouch also acts as a cooling device in the young by providing a large surface for water evaporation. Ungainly on land, pelicans soar impressively in formation at great elevations. All members of the family seem to be voiceless or nearly so.



ALLAN G. CRUICKSHANK FROM THE NATIONAL AUDUBON SOCIETY

BROWN PELICAN (PELECANUS OCCIDENTALIS), ONE OF TWO AMERICAN SPECIES WITH SKIN-POUCH PARTIALLY EXTENDED BY FOOD

One species, the brown pelican (*P. occidentalis*), captures fish by a spectacular plunge from the air; the others swim in formation, driving small schools of fish into shoal water where they are scooped up by the birds. The three or four eggs, white with a rough, chalky shell, require about a month to hatch. The young are naked and black when hatched. As they become larger, they push their bills so deeply into the pouch of the parent while feeding on regurgitated fish as to give rise to the myth that they are feeding on blood from the breast of the parent; this is the basis for the use of the pelican in Christian symbolism to typify the atonement.

The white pelican (*P. erythrorhynchos*) nests on islands of lakes in the Great Basin of North America north to Great Slave Lake and south to the coast of Texas; this species winters on the seacoasts. The brown pelican, with brown and silver-gray plumage, is a coastal bird, ranging from Florida to California and southward on the western coast of South America, where it breeds in enormous colonies, contributing to one of the important depositories of bird fertilizer, or guano. The white or roseate pelican (*P. onocrotalus*) of Eurasia and Africa is similar to the American white pelican except that the plumage is suffused with a delicate pink. Perhaps the most attractively coloured species is the black and white Australian pelican (*P. conspicillatus*).

(Dn. A.)

PELION (modern Gr. Pílion), a mountain in Thessaly, Greece, in the *nomos* (department) of Magnesia (Magnisía), between the town of Vólos and the east coast; highest point 1,601 m. (5,253 ft.), Pílion peak 1,547 m. (5,075 ft.). Its western flank is the more sheltered, and is well wooded. On that side it overlooks the Bay of Vólos or Pagasitikós Kólpos where there were several ancient ports (Iolcos, Pagasae). In Greek mythology the giants piled it on Ossa (*q.v.*), another mountain in Thessaly, to scale Olympus, the abode of the gods. It was the home of the centaurs, especially of Chiron (*q.v.*) who educated many heroes in a cave near its summit. The ship "Argo" of the Argonauts was built from wood from trees on Pelion. At an altar of Zeus Actaeus on its summit a festival was held in the dog days.

PÉLISSIER, AIMABLE JEAN JACQUES, Duc de Malakoff (1794–1864), French army officer, one of the conquerors of Algeria and the last French commander in chief in the Crimean War, was born at Maromme (Seine-Inférieure) on Nov. 6, 1794. With commissioned rank from 1815, he took part in the expeditions to Spain (1823) and to the Peloponnese (1828–29). After his first brief service in Algeria (1830), he returned there in 1839, with the rank of lieutenant-colonel, having meanwhile learned some Arabic. Chief of staff of a division, he campaigned against Abd-el-Kader, but shocked European opinion by smoking to death the Ouled-Riah tribe when it took shelter in caves near Mostaganem (June 1845). Bugeaud, however, protected him; and

Pélissier, promoted general in 1846, was commander of the Oran Province from 1848 to 1851. His furious temper and his sarcasm became notorious.

During the Crimean War (*q.v.*) when Gen. F. C. Canrobert failed to take Sevastopol, Pélissier was first given command of an army corps (Jan. 1855), then appointed commander in chief (May 16). His attack of June 18 on the fort of Malakhov (Malakoff) was unsuccessful, but he defeated a counterattack on the Traktir bridge over the Chernaya River on Aug. 16, and both Malakhov and Sevastopol itself fell on Sept. 8. On Sept. 12, 1855, Pélissier was made marshal of France. On July 5, 1858, he was created duc de Malakoff.

From March 1858 to April 1859 Pélissier was French ambassador to London. During the war of 1858 against Austria (*see* ITALIAN INDEPENDENCE, WARS OF) he commanded the army of the Rhine. In November 1860 he was appointed governor of Algeria. He died in Algiers on May 22, 1864. His savage character could not detract from his martial ability or from his gift of leadership.

See V. E. Derrécagaix, *Le Maréchal Pélissier* (1911). (L. G.)

PELLA, ancient capital of Macedonia, situated in northern Greece about 24 mi. NW of Salonika. The original name was Bounomos, which may have been applied to the island of Phakos where prehistoric remains have been found, and which in classical times was a stronghold where the royal treasury was located. In the 5th century B.C. Pella occupied a narrow strip of land along the sea. By early Roman times this arm of the sea had so far silted up that there was a great marsh in front of Pella, and the town was accessible from the sea only by a channel 15 mi. long. The marsh has been drained, and a fertile plain stretches to the sea 20 mi. away.

Pella first came into prominence when King Archelaus moved the capital there from Aegae (modern Edessa) at the end of the 5th century B.C. It developed rapidly under Philip II. Alexander the Great was born there. After the defeat of the last Macedonian king by the Romans (168 B.C.) Pella sank to a small provincial town.

The site of Pella has long been known, and tumuli on the outskirts of the city marked its approximate limits. Excavations by the Greek Archaeological Service begun in 1957 have revealed large, well-built houses with colonnaded courts and rooms with mosaic floors which have figured panels portraying such scenes as a lion hunt and Dionysus riding a panther. These mosaics are made with small natural pebbles of various colours, carefully matched and laid, and are masterpieces of their kind. Their date is late 4th century B.C. The town was laid out on a rectangular grid plan with streets over 30 ft. wide. Under the streets are terra-cotta pipes for distributing fresh water.

BIBLIOGRAPHY.—P. Petsas in *Illustrated London News,* pp. 197–199 (August 2, 1958) and in *Archaeology,* vol. xi, pp. 246 ff. (1958); coloured reproduction of mosaic in M. Robertson, *Greek Painting,* pp. 166 ff. (1959). (E. V.)

PELLAGRA, a dietary deficiency disease, noncontagious, and occurring in persons of any age, of either sex, of any race, and in any stratum of society. Until rather recently it was considered by many to be merely a disease of the skin, the Italian term *pelle agra* meaning "rough skin." For more than 200 years it was associated especially with maize-eating areas of the world—maize being notably deficient in niacin (*see* below). However, pellagra may result from inadequate diet under many circumstances, prominently including alcoholism.

Some of the early symptoms are weakness, apathy, loss of appetite, indigestion, and neurasthenia. In the late stages of the disease appear the classical four D's: dermatitis, diarrhea, dementia, and death. The symptoms vary greatly in each case. If dermatitis is present it begins as an erythema resembling sunburn that becomes reddish brown, roughened, and scaly. Lesions may appear on any portion of the body, but the commonest sites are the hands, wrists, elbows, under the breasts, knees, feet, and perineal regions. A sharp line of demarcation separates the lesion from the healthy skin. Glossitis and stomatitis are common symptoms. The tongue becomes red and thickened and the mucous membrane is reddened. Severe watery diarrhea often is present in the acute stage. Nervousness, insomnia, headache, and dizziness may be present, and pellagrins are subject to periods of depression and apprehension. Unless early and adequate treatment is administered, confusion, hallucinations, and complete disorientation as to time, place, and person develop. Death inevitably occurs unless the afflicted person receives prompt and intensive treatment.

The pellagrin is relieved of his disease when niacin (a member of the B group of vitamins) and substances that act similarly are given in adequate amounts. The diet of the pellagrin is deficient not only in niacin but also in thiamine (vitamin B_1), riboflavin (vitamin B_2), and folic acid (folacin), as well as many other essential nutrients. (*See* VITAMINS.) Physicians remedy all these deficiencies at the same time and call the tablets or capsules they use "mixed vitamin therapy." Persons who develop symptoms of pellagra, beriberi (*q.v.*), riboflavin deficiency, or folic acid deficiency not only should receive mixed vitamin therapy but they should have a diet rich in lean meat, eggs, milk, fruit, and vegetables. Dried brewers' yeast powder and crude liver extracts contain these vitamins and many other useful nutrients.

PELLICO, SILVIO (1789–1854), Italian patriot, dramatist, and author of *Le mie prigioni* (1832; *My Prisons*), an account of his sufferings as a political prisoner regarded as more damaging to the Austrians than the loss of a battle, which inspired widespread sympathy for the Risorgimento (*see* ITALY). He was born at Saluzzo, Piedmont, on June 25, 1789, and educated at Turin, later spending four years in France, returning in 1809 to Milan, where he began his career as poet and playwright. His romantic tragedy *Francesca da Rimini* (published 1818) was an immediate success on its first performance (1815), and was followed by several others. He had already become one of the circle of Romantic revolutionaries including Monti, Foscolo, Berchet, and Manzoni, and in 1818 he collaborated with Count Luigi Porro Lambertenghi and Count Federico Confalonieri in founding a liberal and patriotic newspaper, *Il Conciliatore,* of which he became editor. After its suppression by the Austrian police (1819) and a disappointment in love, he joined the Carbonari, and in October 1820, was arrested for treason. In 1822 he was sentenced to death, but the sentence was commuted to 15 years' imprisonment in the Spielberg fortress in Brünn (Brno), where he remained until 1830. The rest of his life was spent at Turin, where from 1838 he lived with the Marchese Carlo Tancredi di Barolo and his wife. He died there on Jan. 31, 1854. He had continued to write plays, poetry, and prose works, notably the didactic treatise *I dovere degli uomini* (1834), but *Le mie prigioni* is his only work still widely read and translated. It has become a classic for its simple, direct style and for its revelation of spiritual experience and Christian piety.

Molpurgo (1906; enlarged ed. 1961, containing the additional chapters, *Capitoli aggiunti,* publ. in French, 1843; in Italian, 1856). Of several English translations *see* that by I. G. Capaldi (Oxford Library of Italian Classics, 1963). *See* also *I doveri degli uomini e La Francesca da Rimini,* with notes and introduction (1932); *Le piu belle pagine di S. Pellico,* ed. by G. Deledda (1934); A. Gustarelli, *La Vita, "Le mie prigione" e "I doveri degli uomini" di S. Pellico* (1917); B. Allason, *La Vita di S. Pellico* (1933).

PELLITORY, any small annual or perennial herb of the genus *Parietaria* of the nettle family (Urticaceae), but without the stinging hairs. There are about four species in North America, the chief one being the annual *P. pennsylvanica,* a weedy plant of the southern and north central U.S., about 1½ ft. high, with unisexual, greenish, inconspicuous flowers. The Eurasian *P. officinalis,* a perennial with a woody rootstock, has a stem 1–2 ft. high, bearing slender leafy branches; it is common throughout most of the British Isles. Spanish pellitory is the drug derived from the root of the North African *Anacyclus pyrethrum,* a composite plant; it has been used to promote the flow of saliva. (N. TR.)

PELLOUTIER, FERNAND (1867–1901), a leading organizer and theoretician of the French labour movement who deeply influenced the philosophy and methods of French anarcho-syndicalist labour unionism, was born in Paris on Oct. 1, 1867. As a young journalist in Saint Nazaire, he became a member of the Parti Ouvrier Français, which was inspired by the ideas of Jules

Guesde; but he turned his back on all political parties when the Guesdists rejected the idea of the general strike, which he and Aristide Briand advocated. Becoming an anarchist, Pelloutier was named secretary of the Fédération Nationale des Bourses du Travail in 1895. The *bourses du travail* were a distinctive French institution combining the functions of workers' clubs, employment exchanges, and local labour union federations. They were the most vital element in the growing French trade union movement of the time.

Pelloutier was one of the rare French labour leaders who, while preaching social revolution, nevertheless paid scrupulous attention to the practical details of trade-union organizing and "housekeeping," and to the need for immediate gains in workers' conditions. Desperately ill, poor, and overworked, he managed, in a short lifetime, to strengthen the *bourses* and their federation, to write extensively on working-class life and problems, and to set forth his own ideals of labour action in his *Histoire des Bourses du travail* (1901). He died in a Paris suburb on March 13, 1901.

PELOPIDAS (d. 364 B.C.), Theban statesman and general, was responsible with his friend Epaminondas (*q.v.*) for the brief Theban hegemony in mainland Greece (371–362 B.C.). In 385 he served in a Theban contingent sent to the support of the Spartans at Mantinea, where he was saved, when dangerously wounded, by Epaminondas. Upon the seizure of the Theban citadel by the Spartans (382) he fled to Athens, and took the lead in a conspiracy to liberate Thebes. In 379 his party surprised and killed their chief political opponents and roused the people against the Spartan garrison, which surrendered. In this and subsequent years he was elected boeotarch, and in 375 he routed a much larger Spartan force at Tegyra (near Orchomenos). This victory he owed mainly to the valour of the Sacred Band, a picked body of 300 infantry which also distinguished itself under Pelopidas at the Battle of Leuctra (371). In 370 he accompanied Epaminondas as boeotarch into the Peloponnese. On their return both generals were unsuccessfully accused of having retained their command beyond the legal term. In 369, in response to a petition of the Thessalians, Pelopidas was sent with an army against Alexander, tyrant of Pherae. After driving Alexander out, he passed into Macedonia and arbitrated between the Macedonian king Alexander II and his rival Ptolemaeus. Next year Pelopidas was again called upon to interfere in Macedonia, but on his return through Thessaly he was seized by Alexander of Pherae and two expeditions from Thebes were needed to secure his release. On one or other of his expeditions Pelopidas brought back to Thebes numerous Macedonian hostages, including the future king Philip II. In 367 he went on an embassy to the Persian king Artaxerxes II and induced him to prescribe a settlement of Greece according to the wishes of the Thebans. In 364 he received another appeal from the Thessalian towns against Alexander of Pherae. He overthrew the tyrant's far superior force on the ridge of Cynoscephalae; but wishing to kill Alexander with his own hand, he was cut down by the tyrant's guards.

See also THEBES (Greece).

PELOPONNESE (PELOPONNESUS; ancient Greek PELOPONNESOS, modern Greek PELOPÓNNISOS), the part of the Greek peninsula south of the Isthmus of Corinth. The ancient Greeks interpreted the name as *Pelopos nesos,* "island of Pelops" (*q.v.*). The word does not appear in Homer, who seems occasionally to use "Argos" to mean the whole peninsula, as being under the hegemony of Agamemnon of Argos. The name Peloponnesos is usually assumed to derive from this hegemony of the Pelopidae ("Pelops' descendants").

By the 14th century A.D. the Peloponnese was known as "Morea," the Greek for "mulberry"; this word is first found in the 12th century applied to Elis, a mulberry-growing district, being later extended to cover the whole of the peninsula. *See* GREECE; *see* also references under "Peloponnese (Peloponnesus)" in the Index.

See A. Philippson, *Die griechische Landschaften,* vol. iii (1959).

PELOPONNESIAN WAR. The Peloponnesian War (431–404 B.C.), between Sparta and Athens, was recorded by the most penetrating and important historian of military and political events in antiquity, Thucydides of Athens, whose mature years coincided with the war. Himself a combatant and a general, exiled in 424, he had access to both sides. As his sources of information were immediate, personal, and numerous, he sifted them himself and presented his own narrative, which we have not the evidence to disprove nor in general the desire to challenge because the whole tenor of the work supports his claim to have been meticulously accurate and unbiased (*see* THUCYDIDES). In terms of power and politics, as Thucydides foresaw, the war was decisive. He laid less emphasis on the economic and social consequences for Greek civilization (to which modern writers attach importance), because he was concerned with the interplay of human psychology and of circumstance in the sphere of war and politics.

The Antecedents of the War.—The Thirty Years' Treaty of 445 was a pact of nonaggression between the two leading blocs of power in Greece: Athens and its empire, which comprised most of the islands and maritime states on the northern and eastern coasts of the Aegean basin, and the Greek states of the Propontis and Black seas; and Sparta and its allies, among whom most of the leading land powers in the Peloponnese and central Greece were counted, and also Corinth, the leading sea power in the western seas, which extended to Sicily. So long as neither bloc trespassed on the other's sphere of influence, the peace was likely to last, because the balance between them was in equipoise and the outside powers were neutral. But in 433 Athens made a defensive alliance with a recalcitrant colony of Corinth, Corcyra, which held a strategic position in the western seas and possessed a large fleet of 120 triremes. This alliance infringed the principle but not the letter of the Thirty Years' Treaty and resulted in a clash between Athenian and Corinthian ships when Corinth and its allies attacked Corcyra. In the ensuing winter Athens not only banned one of these allies, Megara, from access to the eastern seas, which had been guaranteed under the Thirty Years' Treaty, but also ordered one of its own allies, Potidaea, which was a colony of Corinth, to break off relations with its founder city and dismantle its seaward walls. These were no idle threats, because the fleet of Athens dominated the Aegean basin. Nevertheless, Potidaea refused. "Volunteers" from Corinth and its Peloponnesian allies reached Potidaea and enabled it to beat off an Athenian attack.

Corinth, Megara, and other states now maintained that Athens had committed aggression and had thus infringed the terms of the Thirty Years' Treaty. They complained, therefore, to Sparta. The Spartans' local interests were not involved. Yet their position at the head of the Spartan alliance was endangered by Athens' moves against two of its members, Corinth and Megara. The executive authorities at Sparta had already made a secret agreement to help Potidaea, but this fact was not known to the Spartan citizens when they met in the assembly to decide their attitude. A large majority found Athens guilty of aggression. The allies of Sparta, meeting in a formal congress, confirmed Sparta's verdict. The two components of the Spartan alliance or, as it is commonly called, the Peloponnesian League, declared themselves ready to go to war if the Athenians proved unwilling to withdraw their ban on Megara and their order to Potidaea.

The decision lay with Athens. The people were swayed by their leading statesman, Pericles (*q.v.*), who had himself proposed the alliance with Corcyra and the ban on Megara. He warned the assembly against yielding to any demands made by the Peloponnesians. The majority accepted his advice. The demands of Sparta were rejected. A diplomatic deadlock ensued. The Athenians offered to accept arbitration on the points under dispute. The Spartans refused arbitration. In spring 431 an ally of Sparta, Thebes, made a treacherous attack on an ally of Athens, Plataea. The Thirty Years' Treaty was flagrantly broken, and both blocs of power went to war. As Thucydides rightly observed, the fundamental cause of the war was the interaction of two forces, the growing power of Athens and the growing apprehension of Sparta.

The First Part of the War ("The Archidamian War," 431–421 B.C.).—The armies of Sparta and its allies were far stronger

than those of Athens. But they could be deployed for only a few months each year, because the Spartans had to keep their serfs, the helots, under control, and the allied soldiers were needed on their farms. The Spartans hoped to force a decisive battle on land. Otherwise there was little hope of success, for Sparta and its allies had relatively small fleets and no financial resources for building large numbers of warships. On the other hand, the fleet of Athens, even without the squadrons of Lesbos, Chios, and Corcyra, was unrivaled; and the Athenians had large financial reserves and access to shipbuilding materials. Their infantry, though outmatched by the combined forces of their enemies, included a striking force of 13,000 men, free to operate at any time and capable of damaging their neighbours individually, and a reserve force of 16,000 men, able to hold the massive walls which circled Athens and the Piraeus and linked the city with its port.

Sparta's lines of communication with its allies beyond the isthmus —Boeotia, Phocis, and Locris—ran through the narrow corridor of northern Megaris which separates Attica from the Corinthian Gulf. This corridor was threatened from the east by Athens and from the west by Athens' ally Plataea. In their desire to control the corridor the Thebans attacked Plataea in March 431. The attack failed. Athens evacuated the noncombatants from Plataea and sent troops to reinforce the garrison. In May the Spartan king Archidamus led the allied armies slowly into Attica and ravaged part of the plain north of Athens, hoping to provoke an engagement. But on the orders of Pericles the Athenian population and the Athenian army were concentrated behind the walls of the city. Although the troops wanted to attack, Pericles held them back. He had no intention of offering battle then or later to the superior army of the enemy. He proposed to conserve his forces for a war of attrition during which the Athenian fleet would guard the empire and Athens' supplies and wear down the enemy by seaborne raids. In June, therefore, before the Spartans left Attica, a fleet of 150 triremes set off from the Piraeus. It raided the coasts of the Peloponnese and closed the mouth of the Corinthian Gulf by winning over Cephallenia (Cephalonia), an island off the entrance to the gulf, as a base. Meanwhile a fleet of 30 triremes ravaged the coast of Locris and garrisoned the island of Atalante in the Euboean Channel, through which convoys passed to an Athenian army blockading Potidaea. The people of Aegina were expelled, and the Athenians occupied the island, which held the entry to the Saronic Gulf. Thus the net of naval blockade was closing round the enemies of Athens and its own sea-lanes were secure.

The policy of Pericles was a wise one in the opinion of Thucydides. It safeguarded the city, the fleet, and the empire—the sources from which Athens drew its financial and naval strength. Even if it meant the loss of property in Attica, which was relatively unimportant, it involved no risks for the Athenian army; and Pericles was confident that he could maintain the morale of the people. In 431 and subsequent years the army ravaged the Megarid. In March 430 Pericles proclaimed his faith in Athens when he delivered a funeral speech in honour of the Athenian dead. But shortly afterward, when the Peloponnesian army was ravaging Attica for the second time, an unexpected blow fell on the crowded city of Athens—a terrible plague which within three years killed one-third of its best troops and maimed many others, apart from its toll among the civilian population. Pericles himself was one of the casualties. The power and the morale of the Athenians were seriously undermined, but they fought on with grim determination in Chalcidice, capturing Potidaea and instigating an extensive raid on Chalcidice and Macedonia by their ally, the Thracian king Sitalces, in 429.

While the plague raged at Athens, the initiative lay with the Spartans. They tried to oust the Athenians from their bases in the western area—Zacynthus, Cephallenia, Acarnania and Amphilochian Argos, Corcyra, and, in the Gulf of Corinth, Naupactus—and thus to regain contact with Italy and Sicily, where they had allies and sources of supply. In 430, attacks on Zacynthus and Amphilochian Argos failed. In 429 a large army of Peloponnesians, Ambraciots, and light-armed levies from the tribes of Epirus invaded Acarnania but suffered defeat at Stratus. A Peloponnesian fleet of 47 warships and smaller troop-carrying vessels, which had intended to join the attack on Acarnania, was intercepted as it sailed out of the Corinthian Gulf by an Athenian squadron of 20 warships based at Naupactus. When the Peloponnesian warships formed a circle, facing outward to protect the smaller vessels at the centre, the Athenian commander Phormion ordered his warships to row round the outside of the circle, which contracted and fell into confusion. Phormion then attacked and gained a remarkable victory. The Peloponnesian fleet then threatened Naupactus. But Phormion won another victory, and reinforcements from Athens soon reached Naupactus. Later in the year the Peloponnesians set out to raid the Piraeus by sea; but their courage deserted them and they raided the island of Salamis instead. The other objective of Sparta in 429 was Plataea. When diplomacy failed, the Spartans built a double wall round the town and imposed a blockade which was destined to last into 427.

In 428 the Peloponnesians made no further move in the western area, but an important opportunity arose for intervention in Aegean waters. Lesbos, one of the two allies of Athens which had a fleet, was planning to revolt and allied itself in August with the Spartans, who undertook to invade Attica that autumn and to send help overseas to Lesbos. But the Athenians moved first, blockading the leader of the revolt, the city of Mytilene, with a squadron of 40 ships, and ravaging the east coast of the Peloponnese with an army transported on 100 ships. The Peloponnesians failed to invade Attica or to send help to Mytilene. During the winter Mytilene was hard pressed by the Athenians. The oligarchs in the town who had organized the revolt found themselves threatened by the democratic party, and they surrendered to the Athenian commander on condition that the Athenian people should make a final settlement. A week later a Peloponnesian squadron of 42 ships crossed the Aegean Sea, learned of the surrender, and sailed ignominiously home. The only success that Sparta gained during the years of the plague was the capture in 427 of Plataea, from which half the garrison had made a brilliant escape at night. The remainder surrendered, entrusting their fate to Spartan courts.

The strain of war lowered the standard of humanity on both sides. The Athenians, incited by a violent orator, Cleon, ordered the execution of all adult males at Mytilene and the enslavement of the rest. Next day the assembly repented. The order was countermanded just in time, but even so a thousand ringleaders were executed. The Spartans condemned and executed the captured garrison of Plataea and the town was demolished by the Thebans. In Corcyra a terrible civil war, fanned by the intervention of a Peloponnesian squadron and later of an Athenian squadron, caused much loss of life and degenerated into guerrilla warfare, which lasted until 425. Supplies were now short in the Peloponnese. At Athens financial reserves were running low, and bitter animosity developed between the extreme democrats, led by Cleon, and the moderate party with which Thucydides and Aristophanes sympathized.

In 427–424 the Athenians abandoned the cautious strategy of Pericles and engaged in a series of offensives. An attack on Melos failed (426). A squadron of 20 ships started operations in 427 against Syracuse in Sicily, where Athens had allies, and gained control of the Strait of Messina; 40 more ships were sent in 425, but the Sicilian states made peace among themselves in 424 and so ended Athenian intervention. An enterprising general, Demosthenes, tried to extend Athens' power in western Greece by attacking Leukas and invading Aetolia, where he suffered defeat. In 426 the Spartans retaliated. Campaigning along the northern coast of the Corinthian Gulf and then joining the Ambraciots in an attack on Amphilochian Argos, they hoped to reduce Acarnania and control the northwestern mainland. But Demosthenes came up with 20 Athenian ships, took command of the Acarnanians and Amphilochians, and inflicted a double defeat on Sparta and Ambracia. His success was so great that the Acarnanians were alarmed and made a separate alliance with Ambracia. From this Athens derived no advantage.

In 425, when the reinforcements were sailing to Sicily, Demosthenes fortified Pylos, a rocky promontory on the west coast of Messenia, and stayed there with a small force. A Peloponnesian

fleet of 60 ships, which had been operating at Corcyra, hastened south to Pylos and landed 420 Spartans on an island, Sphacteria, hoping to blockade the promontory. The Athenian fleet returned suddenly, defeated the Peloponnesian fleet by surprise and isolated the Spartans on Sphacteria. Sparta then negotiated an armistice at Pylos, during which the Athenians were given possession of the Peloponnesian fleet as a guarantee of good faith. Sparta offered peace and alliance to Athens. Cleon persuaded the assembly to reject the offer in the hope of winning some decisive victory, and later in the year he was sent out to take command with Demosthenes at Pylos. There the Athenians, alleging a technical breach of the armistice, had refused to return the Peloponnesian ships but failed to land on Sphacteria. Cleon and Demosthenes, encouraged by a fire which burned the woods on the island, made a landing, fought the Spartans to a standstill, and obtained the surrender of 120 Spartiates.

Stripped of its fleet, shaken in morale, and threatened by helot risings in Messenia, Sparta was now at its lowest ebb. Athens tried to press home its advantage. During the voyage to Sicily the fleet from Pylos connived at a massacre of oligarchs at Corcyra. Nicias led successful raids by sea on the coasts of Corinth and Epidaurus and occupied Methana. In 424 he captured and garrisoned Cythera as a base for raiding Laconia. Demosthenes and Hippocrates came within an ace of capturing Megara and thus cutting the Peloponnese off from Boeotia. In the summer a triple attack was launched on Boeotia, but a failure in the timing and the slowness of the main force under Hippocrates at Delium enabled a Boeotian army of 7,000 hoplites and 1,000 cavalry to force a battle, in which Hippocrates and 1,000 Athenian hoplites were killed. This disaster brought the Athenian offensive to an end.

Meanwhile the Spartans broke out of the net in which the Athenians sought to enclose them. An able Spartan officer, Brasidas, having saved Megara from capture by Demosthenes and Hippocrates, led an army of Peloponnesian troops and freed helots into Chalcidice, an area neglected by Athens since the fall of Potidaea. There he raised city after city in revolt from Athens and in December 424 captured Amphipolis, Athens' chief base in the northwest Aegean. Athens tried to stop the landslide by concluding a year's armistice with Sparta, but it proved ineffective in Chalcidice, where Brasidas continued to detach states from the Athenian empire. Afraid of more widespread revolt, the Athenians sent an army under Cleon's command to recapture Amphipolis in 422. It was decisively defeated; Cleon was killed, but so was Brasidas. Nicias, Cleon's rival, now persuaded the assembly to accept the overtures for peace that Sparta had been making since 425. A treaty of peace was accepted in 421 by Athens and Sparta, but not by four of Sparta's leading allies (Boeotia, Corinth, Elis, and Megara). Soon afterward Athens and Sparta entered into a defensive alliance, not of goodwill but of convenience.

The Ineffective Peace, 421–415 B.C.—These years gave the Athenians an opportunity to seduce Sparta's allies and isolate Sparta by diplomacy. They failed to use it because they were split internally by the rival policies of appeasement, led by Nicias, and of aggression, led by Alcibiades. The other states now distrusted both Athens and Sparta, but a breakaway group of Argos, Corinth, Elis, and Mantinea was too weak to withstand either great power. In the atmosphere of general mistrust the terms of the so-called Peace of Nicias were never implemented. Sparta managed to make an alliance with Boeotia, and Athens won over Argos, Elis, and Mantinea, but not Corinth, in 420. Sparta took military action in 418. The Spartan army of 6,000 hoplites and the levies of Boeotia, Megara, Corinth, Tegea, and lesser allies outmaneuvered the forces of Argos (numbering 6,000 hoplites), Elis, Mantinea, and some lesser states and imposed an armistice on Argos. Sparta's allies had gone home when Argos received 1,000 hoplites and 300 cavalry from its ally Athens and reopened hostilities. At Mantinea the army of Sparta, aided by Tegea alone, inflicted a decisive defeat on Argos, Mantinea, and Athens, and rapidly reestablished the Spartan alliance as it had been in 431. The feeble intervention of Athens in the Peloponnese with a mere 1,000 hoplites had lost the chance of diplomatic or military success on land. Meanwhile in the north, Amphipolis and Chalcidice remained independent and hostile. The war party at Athens now favoured adventure at sea. In 416 Athens attacked Melos, which refused to renounce neutrality and accept Athens' rule. When Melos capitulated, Athens massacred the adult males, enslaved the rest, and gave the island to 500 Athenian settlers. In 415 the Athenians sent out a great armada to conquer Sicily. These acts showed that their methods were unscrupulous and their ambitions were unlimited. They heralded the end of the Peace of Nicias.

The Second Part of the War, 415–404 B.C.—This was decided at Syracuse and at sea. On this element the Athenians began with complete supremacy. In all they committed 200 warships to the gamble in Sicily, and left their home fleet dangerously weak. The expeditionary force in Sicily was commanded by three incompatible generals, Alcibiades, Lamachus, and Nicias. Alcibiades was soon recalled on a charge of sacrilege; he escaped and transferred his services to Sparta. Lamachus was killed in action. Nicias was soon affected by illness. In 414 the first attempt was made to circumvallate and blockade Syracuse by land (for Athens held command at sea); it failed, mainly because a Spartan, Gylippus, with nearly 3,000 troops slipped through the Athenian lines and enabled the Syracusans to defeat the Athenian land forces, which had had only a small margin of superiority. Nicias then concentrated his army in defense of the naval base by the great harbour and advised Athens to recall the expedition. He was told to await reinforcements.

In July 413, when Nicias had lost his naval base and been defeated at sea, Demosthenes arrived with a large force. It was essential to establish military superiority at once. Demosthenes therefore launched a night attack, suffered a severe defeat, and wished to sail home. Nicias now refused to go. A month later Nicias agreed to sail; but an eclipse of the moon occurring on Aug. 27, 413, Nicias accepted his soothsayers' advice to stay "thrice nine days." While he stayed, the fate of the expedition was decided in the Great Harbour; the morale of the Athenian navy was broken by a single defeat and the whole force attempted to escape overland. It suffered complete destruction. Mismanagement, indecision, and panic thus cost Athens more than 200 warships with crews totaling about 35,000 men, a fine army including 4,000 Athenians, and much material and treasure.

The Spartans and their allies declared war in 414. On the advice of Alcibiades, they established a fortified post at Decelea in northern Attica which denied the Athenians the use of Attica and made them import all foodstuffs by sea at great expense. The Athenian disaster in Sicily gave Sparta hope of winning at sea. With Alcibiades' help the Spartans entered into alliance with the king of Persia, who could provide bases and money; they were joined by Chios, Miletus, and other states which revolted from Athens; and a small Peloponnesian fleet established itself at Miletus. The Athenians showed great energy; they built ships quickly, secured Samos as their main base, and covered their chief line of supply through the Hellespont. In 411 Abydos in the Hellespont revolted with the help of a Spartan force and Persia. At this stage the Persian king adopted a waiting game on the advice of Alcibiades, who suggested that he let the Greeks wear one another down and use his wealth to end the war at his pleasure. Alcibiades engineered his own recall to the Athenian fleet at Samos. He began by promoting an oligarchic revolution which developed partly from the hypothesis that as an oligarchic leader he could obtain aid from Persia. Oligarchy at Samos was short-lived but the succeeding democratic leaders appointed Alcibiades general of the fleet. Meanwhile at Athens an oligarchy seized power, ruled despotically, and negotiated with Sparta for terms of peace. It was overthrown by a popular rising, and a moderate government, known as "the five thousand," took its place and cooperated with the democratic fleet at Samos. The slowness of Sparta and the deliberate inaction of Persia gave Athens the chance to ride out the storms of disaster in Sicily and of revolution at home. Late in 411 the Athenians won their first victory against the Peloponnesian navy at Cynossema in the Hellespont. Two more victories followed. They put the main enemy fleet out of action for three years, and merged the two governments at Samos and Athens in a restored democracy.

The democratic leaders, especially Cleophon, pushed the war

to the finish by rejecting the terms which Sparta repeatedly offered and by attacking those who advocated negotiation as oligarchs. Neither side had the money to outdo the other. Alcibiades came home in triumph in 407, but Persia chose to subsidize the Spartan admiral, Lysander, who equipped 90 ships and defeated an Athenian fleet. Alcibiades was held responsible by the Athenians; he fled into exile in 406. By tremendous efforts the Athenians survived further defeats at sea, manned 150 ships, and won a battle at Arginusae in which about 20,000 Greek lives were lost. The Persian policy of attrition was now coming to an end. In 405 the Persian prince Cyrus enabled Lysander to man 200 ships. He entered the Hellespont, drew the Athenian fleet of 180 ships after him, and caught them ashore in a sudden attack at Aegospotami. Only eight ships escaped. The Athenian navy was no more. The relentless advance of Lysander to the Piraeus and the blockade imposed from Decelea starved the Athenians into final submission, but only after Cleophon had been executed and the way had been prepared for an oligarchic government. In April 404 Lysander's troops began to demolish the walls of the Piraeus. Athens was to be stripped bare of empire, fleet, and fortifications, so that it should never try again to enslave the Greek states.

The Spartans owed their victory to the tenacity of their government, their excellent infantry, and their power of leadership, but also to the fighting quality of the Syracusans and to the gold of Persia, for which Sparta promised to sacrifice the liberty of the Greeks in Asia. The Athenians owed their failure to instability in government and temperament, mistaken policy, incompetent generalship, and declining morale. Although the principle of national independence was strikingly vindicated by the outcome, the general strength of the Greek states was fatally weakened and the most progressive and civilized state was reduced to impotence.

PELOPS, legendary founder of the Pelopid dynasty at Mycenae in the Greek Peloponnese (Peloponnesus), which was thought to take its name from him. He was the grandson of Zeus, son of Tantalus, and brother of Niobe. Thucydides speaks of him as an Asian who won influence in Greece by his wealth. He was said to have a shoulder of ivory, because his father, Tantalus, on terms of intimacy with the gods, had served his son up to them at a banquet; though only Demeter—distracted by grief at the loss of her daughter Persephone—ate of the dish, the gods needed to replace the shoulder when they brought Pelops back to life.

Pindar (*Olympian* i) refuses to believe this story and offers an elaborate alternative, showing how free poets felt to change traditional accounts. Poseidon loved Pelops and took him up to heaven. The ghastly feast was merely malicious gossip to account for his disappearance. Unlike Ganymede, however, Pelops had to return to mortal life because his father abused the favour of heaven by feeding nectar and ambrosia, of which only gods partake, to mere mortals (*see* TANTALUS). Nothing daunted, Pelops strove for the hand of Hippodamia, daughter of King Oenomaus of Pisa in Elis. Oenomaus used to challenge his daughter's suitors to a chariot race, with Hippodamia the prize of victory and death the price of defeat. Oenomaus had already won on at least 12 occasions, since his team and chariot were the gift of his father, Ares. Pelops, however, had a chariot from Poseidon, won the bride and killed Oenomaus. Thus far Pindar.

In more hostile versions, Pelops bribed Oenomaus' charioteer, Myrtilus, to replace Oenomaus' linchpins with wax dummies, and then after his victory threw Myrtilus into the "Myrtoan" sea near Geraestus in Euboea to avoid paying what he had promised—in some versions the favours of Hippodamia. Myrtilus—or Oenomaus—was said by some to have uttered the curse that dogged the Pelopid house of Atreus. (For the history of this house, *see* ATREUS; AGAMEMNON.) Pelops was sacrificed to as a hero at Olympia as part of the festival of the games, with which he and his charioteering are obviously connected. His tomb was shown there. (G. E. DK.)

PELOTA: *see* JAI-ALAI.

PELOTAS, a port in the state of Rio Grande do Sul, Braz., located on the left bank of the Canal de São Gonçalo, the river that connects Lagoa Mirim with Lagoa dos Patos. The population in 1960 was 121,280. Pelotas was founded in 1830 and became a city in 1835. Together with the port of Rio Grande, 32 km. (20 mi.) SSE, it serves as the transfer point between lake and ocean shipping. Ocean steamers, after crossing the bar at the outlet of Lagoa dos Patos, can reach both Rio Grande and Pelotas but cannot reach Pôrto Alegre fully loaded. Pelotas also serves as the chief port for the cattle-ranching area of southern Rio Grande do Sul. It is Brazil's largest producer of *xarque*, or jerked beef, and has meat-packing plants, flour mills, tanneries, and factories producing lard, soap, candles, shoes, and furniture. Wool, hides, dairy products, rice, and timber are exported from Pelotas. The city is connected by rail and highway with Rio Grande, with Bagé, and with the Uruguayan border at Jaguarão. It is reached by lake steamer from Pôrto Alegre and is served by Brazilian and international airlines. (P. E. J.)

PELTIER, JEAN CHARLES ATHANASE (1785–1845), French physicist, whose discovery (1834) that an electric current produces, according to direction, either heat or cold at the junction of two dissimilar metals in a circuit is called the Peltier effect. Peltier is also remembered for introducing the concept of electrostatic induction. He was born at Ham (Somme), France, on Feb. 22, 1785, and became a clockmaker. He died in Paris on Oct. 27, 1845. *See* ELECTRICITY, ATMOSPHERIC: *History;* HEAT: *Radiation: Absolute Radiometers.* (D. MCK.)

PELUSIUM, an ancient Egyptian city on the most easterly (now silted) mouth of the Nile, probably called by the Egyptians Sa'inu and also Per-Amun, "House of Amon," whence perhaps the modern name of the site, Tell Farama, about 32 km. (20 mi.) SE of Port Said. In the late period of pharaonic history Pelusium replaced Sile as the frontier fortress against Palestine and as a customs post for Asiatic goods. Cambyses the Persian was the first of many invaders to meet with resistance there. In Roman times it was a station on the route to the Red Sea. (M. S. DR.)

PEMBA, an island in the Indian ocean off the east coast of Africa, forming part of the United Republic of Tanganyika and Zanzibar (*q.v.*), lies about 25 mi. (40 km.) N.N.E. of Zanzibar Island and 30 mi. (48 km.) from the coast of Tanganyika. Area, including offshore islets, 380 sq.mi. (984 sq.km.). Pop. (1958 census) 133,858, mostly Africans (including the aboriginal Pemba or Wapemba) but with a large Arab minority and some Indians. Formed and detached from the continent in the Miocene Age, Pemba is based upon various limestones including coral. Much of the island consists of small but steep undulating hills, and the western and southern coast line is deeply indented with creeks and bays characterized by dense mangrove vegetation. The rainfall is greater than that of Zanzibar but the climate is similar. Figures for Wete, the capital, are: mean annual rainfall 77 in., mean maximum temperature 30° C. (86° F.), mean minimum 23° C. (73° F.). Pemba has evidence of 10th- to 16th-century Persian settlement, and the indigenous people claim Persian affinity, calling themselves Shirazis. The Portuguese built settlements there in the 16th and 17th centuries, introducing the black domestic pig, which is now wild, and bullfighting, which is still practised. In the early days of Arab supremacy the Mazrui Arabs regarded themselves as independent of Zanzibar. Even when Pemba came under the sultan it remained a stronghold of slavery and slave running until the end of the 19th century. Much of Pemba is extremely fertile and it produces more than three-quarters of the republic's clove crop. There are three small towns: Wete in the north, Chake Chake in the centre and Mkoani in the south. Wete and Mkoani have good

port facilities. There are 70 mi. (113 km.) of motor roads. There is a small airstrip near Chake Chake and the island is in wireless contact with Zanzibar from which a weekly shipping service operates. (F. B. Wi.)

PEMBROKE, EARLS OF. The title of earl of Pembroke has been held successively by several English families. The earldom, created in 1138, was conferred by King Stephen on Gilbert de Clare (d. *c.* 1148), who inherited the lordship of Chepstow (or Striguil) from his uncle, Walter. In the civil war, Gilbert at first supported Stephen against the empress Matilda, but he was involved in Geoffrey de Mandeville's conspiracy in 1142 and rebelled against the king in 1147. From his son Richard (d. 1176) the earldom passed to William Marshal (d. 1219), who married Richard's daughter and heiress, Isabel (d. 1220). (*See* Pembroke, Richard de Clare, 2nd earl of; Pembroke, William Marshal, 1st earl of.)

William Marshal's five sons succeeded in turn to the earldom and all died childless. His eldest son, Earl William (d. 1231), was one of the 25 barons appointed in 1215 to safeguard the keeping of Magna Carta. In 1223 he defeated the Welsh prince Llewelyn ab Iorwerth and checked the extension of his power; his second wife, Henry III's sister, Eleanor, later married Simon de Montfort. Earl Richard (d. 1234) led in 1233–34 the baronial opposition which compelled the dismissal of the king's Poitevin ministers, Peter des Roches and Peter des Rivaux. While defending (Feb. 1234) his Irish possessions, which had been acquired by the marriage of Earl Richard de Clare (d. 1176) to Eva, daughter of Dermot Mac Murrough, king of Leinster, he was captured at Kildare and died of his wounds soon afterward, on April 16. The next earl, Gilbert, received fatal injuries in a tournament in 1241; Anselm (d. 1245), the last earl of the Marshal line, survived his brother, Earl Walter (d. Nov. 24, 1245), by less than a month, and was never invested with the earldom. The family's great estates in England, Wales, and Ireland were then divided among Anselm's five sisters and their descendants.

The earldom of Pembroke was revived for Henry III's favourite half brother, William de Valence (d. 1296), fourth son of Hugh X de Lusignan, count of La Marche, by his marriage with King John's widow, Isabella of Angoulême (d. 1246). William, with his brothers, Guy and Aymer, came to England in 1247 and he was married on Aug. 13 to Joan de Munchensy (d. 1307), a niece of Earl Anselm; her share of the Marshal lands included the lordship of Pembroke. He was one of Henry III's 12 representatives on the Committee of 24 which drafted the Provisions of Oxford (June 1258); later, his resistance to the Provisions resulted in his expulsion from England on July 14. He returned to England at Easter 1261. After the royalist defeat at Lewes on May 14, 1264, he escaped to France and his landing in the lordship of Pembroke in May 1265 began the campaign which led to De Montfort's death at the Battle of Evesham on Aug. 4. His loyalty to the king was rewarded by grants of forfeited estates and in 1270 he accompanied the future Edward I on his crusade. He served in the Welsh wars of 1277 and 1282–83, and in 1279 was the king's representative when the Agenais was transferred to Edward I by Philip III of France. Although not formally created earl of Pembroke, he was sometimes styled as such in Edward I's reign and was summoned to Parliament as earl in 1295.

Aymer de Valence (d. 1324), William's third and only surviving son, was regarded as having succeeded to the earldom after the death of his mother, Joan, in 1307. He was one of the lords ordainers in 1310–11, but in 1312 he joined the court party and was Edward II's chief adviser until 1314. As leader of the baronial "middle party," he was again virtually head of the administration between 1318 and 1321. After the royalist victory at Boroughbridge in 1322, his influence was replaced by that of the Despensers. He died childless in 1324; his second wife, Mary of St. Pol (d. 1377) founded Pembroke College, Cambridge.

The next earl, Aymer's great-nephew, Laurence (1320–1348), Lord Hastings, was recognized by Edward III in 1339 as having inherited the lordship of Pembroke as a county palatine. His son, John (1347–1375), captured by the Spanish in the Battle of La Rochelle in June 1372, died shortly after being ransomed three years later. His son John (1372–1389), the last Hastings earl of Pembroke, died without issue while still a minor, and his titles became extinct.

After being held from 1414 to 1447 by Humphrey (1390–1447), duke of Gloucester, and subsequently by William de la Pole (1396–1450), 1st duke of Suffolk, the earldom of Pembroke was granted, probably on Nov. 23, 1452, to Henry VI's half brother, Jasper Tudor (*c.* 1431–1495), who became the leading supporter of the Lancastrian cause in Wales during the Wars of the Roses (*see* Tudor). His defeat at Mortimer's Cross on Feb. 2, 1461, opened the way for Edward of York to advance to London and dethrone Henry VI; in Edward IV's first Parliament in December 1461, Jasper was attainted and his earldom forfeited. The next holder of the title was Sir William Herbert (*c.* 1423–1469) of Raglan Castle, who was granted the lordship of Pembroke by Edward in February 1462; on Sept. 8, 1468, having defeated Jasper Tudor's raid into North Wales and captured the sole remaining Lancastrian stronghold of Harlech Castle, Herbert was created earl of Pembroke. He incurred the hostility of Richard Neville, earl of Warwick, and was executed, after the Battle of Edgecote, on July 27, 1469. His son, William Herbert (*c.* 1455–1491), received in 1479 the earldom of Huntingdon in exchange for that of Pembroke, which Edward IV conferred on his heir, the future Edward V. Jasper Tudor returned from exile to fight at Bosworth in 1485; on Henry VII's accession he recovered his earldom of Pembroke and soon afterward was created duke of Bedford; but as a result of his death without heirs in 1495 the earldom of Pembroke once more reverted to the crown. (T. B. P.)

Anne Boleyn (*c.* 1507–1536) was created marchioness of Pembroke on Sept. 1, 1532, shortly before her marriage with Henry VIII.

The title of earl of Pembroke was next revived in favour of Sir William Herbert (*c.* 1506–1570), whose father, Richard, was an illegitimate son of Sir William (d. 1467), 1st Herbert earl of Pembroke. His first wife, Anne Parr, was a sister of Catherine Parr who married Henry VIII in 1543. In January 1544 Sir William was granted the rich estates formerly belonging to Wilton Abbey. Appointed a governor to the young king Edward VI, Sir William helped to suppress the rebellion in Devon and Cornwall in 1549, and supported John Dudley, earl of Warwick (afterward duke of Northumberland), against the duke of Somerset. In October 1551 he was created Baron Herbert of Cardiff and earl of Pembroke. After Edward VI's death he did homage to Lady Jane Grey, but withdrew his allegiance in time to attend the proclamation of Mary I in London. Mary made him a privy councilor and he led her troops against the rebel Sir Thomas Wyat early in 1554. On the accession of Queen Elizabeth I Pembroke continued a member of the privy council and from 1568 until his death he was steward of the royal household. Imprisoned in September 1569 for having favoured a proposed marriage between Mary Stuart and the duke of Norfolk, he was quickly released. He died at Hampton Court on March 17, 1570.

His son Henry (*c.* 1538–1601) was president of the Council of Wales from 1586 until 1601 and in 1586 was a commissioner for the trial of Mary Stuart. He married in 1577, as his third wife, Mary Sidney, the famous countess of Pembroke (*q.v.*). He died at Wilton House on Jan. 19, 1601, and was succeeded by his son William (1580–1630). William was lord chamberlain of the royal household (1615–26) and lord steward (1626–30). He took a lively interest in colonial and trading projects and in 1609 was a councilor for the colony of Virginia. He was also a member of various companies established to discover the Northwest Passage. He was chancellor of Oxford University from 1617 to 1630, and when, in 1624, Broadgates Hall was refounded by Thomas Tesdale and Richard Wightwick, it was named Pembroke College after him. (For his identification by some Shakespearean commentators with the "Mr. W. H." of the dedication in the 1609 edition of Shakespeare's sonnets, *see* Shakespeare, William: *The Poems.*) He died without issue on April 10, 1630, and was succeeded by his brother Philip (1584–1650). Philip was for several years a favourite of James I and was created Baron Herbert of Shurland in the Isle of Sheppey and earl of Montgomery on May 4, 1605. He

was with Charles I at York as captain general of a regiment of horse during the Bishops' Wars of 1639 and 1640, but joined the Parliament before the outbreak of the Civil War. Later he was made governor of the Isle of Wight, and represented Parliament in negotiations with the king at Uxbridge in 1645, at Newport in 1648, and when Charles was surrendered by the Scots in 1647. For his services to the parliamentary cause he was voted a dukedom by Parliament on Dec. 1, 1645, and was elected to the House of Commons as a member for Berkshire in 1649. He died at Westminster on Jan. 23, 1650.

Philip's great-grandson THOMAS (*c.* 1656–1733), 8th earl of the second Herbert creation, commanded the trained bands of Hampshire and Wiltshire gathered at Chippenham to oppose the rebels led by the duke of Monmouth in 1685. After the flight of James II in 1688 and the landing of William of Orange, Thomas took to the prince at Henley-on-Thames an invitation signed by many peers and privy councilors. He, who formed the greater part of the collection of pictures at Wilton House, died in London on Jan. 22, 1733. His son HENRY (*c.* 1689–1750) was largely responsible for the erection of Westminster Bridge. Henry's great-grandson ROBERT HENRY (1791–1862), 12th earl, died without issue and the title passed successively to his nephews, GEORGE ROBERT CHARLES (1850–1895) and SIDNEY (1853–1913), the sons of Sidney Herbert, 1st Baron Herbert of Lea, half brother of Robert Henry. SIDNEY CHARLES HERBERT (1906–), the present earl, is a grandson of Sidney (1853–1913).

Evans, *Wales and the Wars of the Roses* (1915).

PEMBROKE, MARY HERBERT, COUNTESS OF (1561–1621), "the subject of all verse," as she is called in a famous epitaph, was the sister to whom Sir Philip Sidney (*q.v.*) dedicated his celebrated *Arcadia,* and was herself a patroness of the arts and of learning. She was born at Ticknell Palace, near Bewdley, Worcestershire, on Oct. 27, 1561, the fifth child of Sir Henry and Lady Mary Sidney. In 1575 Queen Elizabeth I invited her to court, promising to have "a special care" of her, and in 1577 she married Henry Herbert, second earl of Pembroke; their sons, William and Philip, were the "incomparable pair of brethren" to whom Shakespeare's First Folio (1623) was dedicated. (*See* PEMBROKE, EARLS OF.)

After her marriage, Lady Pembroke lived mainly at Wilton House, near Salisbury, Wiltshire, becoming so well-known for her patronage of writers and scholars that, as John Aubrey says in his *Brief Lives,* "in her time Wilton House was like a college, there were so many learned and ingenious persons." Among them were Adrian Gilbert, the chemist and astrologer; Thomas Moffet, the physician, poet, and entomologist; and Samuel Daniel, the poet and historian, who was tutor to her sons. Others who praised her for her patronage of their art were Spenser, Drayton, Nicholas Breton, Thomas Watson, John Davies of Hereford, and William Browne of Tavistock, who wrote the epitaph on her.

After her brother's death in 1586, Lady Pembroke undertook the publication of his works and completed the verse translation of the Psalms of which he had left the first 43. She also translated Robert Garnier's tragedy *Marc-Antoine (Antonius)* and Philippe Duplessis-Mornay's *Discours de la vie et de la mort (A Discourse of Life and Death)* (both 1592) and made a most elegant version in *terza rima* of Petrarch's *Trionfo della morte.* She played the lute, and Thomas Morley dedicated to her his *Canzonets* (1593). Pious and gentle, generous and accomplished, she was the most admired, after the queen herself, of Elizabethan *femmes savantes,* and was fitly compared (in Breton's dedication to her of his *Pilgrimage to Paradise,* 1592) with the duchess of Urbino, patroness of Baldassare Castiglione; in the chorus of contemporary praise, there is not once a discordant note.

Lady Pembroke died in London on Sept. 25, 1621, and was buried in Salisbury Cathedral.

See F. B. Young, *Mary Sidney, Countess of Pembroke* (1912); J. Buxton, *Sir Philip Sidney and the English Renaissance,* 2nd ed. (1964). (E. J. M. BR.)

PEMBROKE, RICHARD DE CLARE, 2ND EARL OF (*c.* 1130–1176), known as "Strongbow" and usually styled earl of Striguil, son of Gilbert de Clare, 1st earl, succeeded to his father's estates in 1148 but had forfeited or lost them by 1168. Probably in that year Earl Richard agreed to help Dermot Mac Murrough, king of Leinster, who had been driven from Ireland in 1166 and had gained permission from Henry II to raise forces in Britain. Dermot in return promised Richard his daughter Eva in marriage and the succession to the kingdom of Leinster. Richard, some of whose vassals had gone on ahead, crossed to Ireland probably in 1170. He took Waterford and Dublin and married Eva. The death of Dermot, in May 1171, provoked a general rising and Richard was besieged in Dublin by the king of Connaught (Connacht) for almost two months. Meanwhile Henry II became uneasy at his vassal's success; Richard crossed to England to meet him and agreed to surrender Dublin and the other coastal towns and to do homage for the remainder of Leinster. He returned to Ireland with Henry in October 1171.

In 1173 Richard went to Normandy to help Henry II against the rebels of 1173–74. He was at the relief of Verneuil in August 1173. Henry probably made him constable of Gisors, and rewarded his loyalty with the grant of Wexford and the custody of Waterford and Dublin. Later Henry committed the whole of Ireland to his care. Richard unsuccessfully invaded Munster in 1174, but his supremacy was eventually recognized in Leinster. He died in Dublin on April 20, 1176, and was buried in Holy Trinity Church (afterward Christ Church Cathedral). His son Gilbert de Striguil died unmarried, certainly before 1189, and as a minor was never styled earl. The earldom passed with Richard's daughter Isabel (d. 1220) to her husband William Marshal (*c.* 1146–1219).

BIBLIOGRAPHY.—G. H. Orpen (ed.), *The Song of Dermot and the Earl* (1892), *Ireland Under the Normans,* vol. i (1911); E. Curtis, *A History of Medieval Ireland from 1014–1513,* 2nd ed. (1938).

PEMBROKE, WILLIAM MARSHAL, 1ST EARL OF (*c.* 1146–1219), *rector regis et regni* (governor of the king and of the kingdom) during the first years of Henry III's minority, was the fourth son of John (FitzGilbert) the Marshal (d. 1165). As a youth he was in the household of William de Tancarville, chamberlain of Normandy, but in 1167 he passed into the service of his uncle, Earl Patrick of Salisbury, after whose death (1168) he entered the service (1170) of Henry Fitzhenry, the young king. From about 1187 he was in the service of Henry II, who promised him for wife Isabel (d. 1220), heiress of "Strongbow," Richard de Clare, earl of Striguil or Pembroke. She was later granted to him by Richard I. Occasionally termed earl during Richard's reign, he seems not to have been formally recognized as such until King John's coronation (May 27, 1199). He succeeded his brother as marshal of England in March 1194. William Marshal, regarded as the foremost knight of his time, by whom the young king chose to be knighted, had a predominantly military career. But he was one of the four barons who, with William Longchamp, bishop of Ely (superseded in October 1191 by Walter of Coutances, archbishop of Rouen), were constituted a council of regency during Richard's absence on crusade, and he occasionally sat on the bench at Westminster. In the early years of John's reign he was continuously engaged in fighting, both in England and in Normandy and Gascony, but from 1207 to 1213 he was mostly in Ireland administering the vast lordship of Leinster which his wife had brought him and which he seems not to have visited previously. He secured the adhesion (*c.* 1212) of the Irish barons to a declaration supporting John in his quarrel with Innocent III, and after his return to England (April 1213) he consistently supported the king and was with him at Runnymede in June 1215.

On John's death (October 1216) William Marshal was appointed guardian (*rector*) of the king and the realm and, together with the papal legate who represented Henry III's feudal superior, Honorius III, he was the virtual ruler of England. He pursued a policy of conciliation and moderation. Magna Carta was reissued (1216 and 1217), shorn of the obnoxious clauses directed against the late king. After his defeat of Louis of France and the dissident

barons at Lincoln (May 20, 1217), and the defeat off Sandwich (August 1217) of a French fleet bringing reinforcements, the Treaty of Kingston was concluded (Sept. 12, 1217). Louis withdrew, a general amnesty was granted, and the normal machinery of government was restored. The extent of William's participation in the administration between 1217 and 1219 is uncertain, though he did not relinquish control. He was, however, feeling the weight of years, and he died at Caversham, Berkshire, on May 14, 1219.

BIBLIOGRAPHY.—*L'Histoire de Guillaume le Maréchal,* ed. by P. Meyer, 3 vol. (1891–1901), which was written *c.* 1225, is indispensable but of unequal value; largely based on it is S. Painter, *William Marshal* (1933). *See* also L. Landon, *Itinerary of King Richard I* (1935).

PEMBROKE, a municipal borough in Pembrokeshire, Wales, comprises the two towns of Pembroke and Pembroke Dock, 1½ mi. apart, on the southern banks of Milford Haven 42 mi. (68 km.) W of Swansea. Pop. (1961) 12,737; Pembroke *c.* 4,500, Pembroke Dock *c.* 8,300.

Pembroke town, now primarily an agricultural and tourist centre, was incorporated by royal charter in 1090 and was once a walled town. Parts of the walls and some of the towers are still standing. The town is built on a limestone ridge around the long Main Street, at the western end of which is the castle. Surrounded by the tidal waters of the Pembroke River on the western and northern sides, the castle was originally a fortress. It was built by Arnulf de Montgomery in 1090, and in the 12th and 13th centuries it was enlarged by the earls palatine of Pembroke who made it their chief seat. Henry VII was born there in 1457. The castle's main feature is the circular vaulted keep built *c.* 1200 by William Marshal, earl of Pembroke, which is 75 ft. (23 m.) high, with walls 19 ft. (6 m.) thick at the base. The Church of St. Nicholas, known as Monkton Priory, was given by Arnulf de Montgomery to the abbey of Sées in Normandy in 1098 and became established as a Benedictine priory. The church was fully restored in 1882. Of the priory buildings the Old Hall and dovecote remain. St. Mary's Church, with a massive Norman tower, was founded in 1260.

Pembroke Dock, primarily industrial, was built as a result of the establishment of a royal dockyard in 1814 on the banks of Milford Haven. The town became a garrison town and still retains a military barracks. The dockyard closed in 1926, and the major part of the yard was handed over to the Royal Air Force in 1931 and used as a flying boat base until 1959. The Royal Navy still retains a small base in part of the old dockyard. Pembroke's main industries are ship-repairing, light engineering, and a woolen mill. (R. D. L.)

PEMBROKESHIRE (SIR BENFRO), the most westerly county of south Wales, is bounded northeast by Cardiganshire, east by Carmarthenshire, south by the Bristol Channel, and west and northwest by St. Bride's Bay and Cardigan Bay of St. George's Channel. The coastline is much indented and more than 160 mi. (257 km.) in length. The geographical area is 614.3 sq.mi. (1,591.0 sq.km.). Pop. (1961) 93,980.

From Haverfordwest (*q.v.*), the county town and main marketing centre, no fewer than ten roads radiate to all parts of the county. Fishguard and Milford Haven have the two most westerly railway termini in Wales. St. David's, nominally a city by possession of a cathedral, is in fact no more than a small village.

Physical Features.—Much of the county consists of undulating or hilly pasture land, the highest ground being in the north, where the Prescelly Hills (Mynydd Preseli) reach 1,760 ft. (536 m.). There are numerous streams, but the only rivers of importance are the East and West Cleddau, whose estuaries merge about 4 mi. (6 km.) SE of Haverfordwest and extend south to Milford Haven, thus severing direct communication between the Pembroke peninsula and the rest of the county. There are magnificent cliffs along the south coast, gray Mountain Limestone alternating with Old Red Sandstone. The long, narrow inlets represent drowned valleys and there are many sandy bays. There are submerged forests in the vicinity of Amroth. The north and south arms of St. Bride's Bay are prolonged by groups of small islands, of which Skokholm, Skomer, and Grassholm are well-known breeding places of seabirds. The islands are protected, and the Council for the Promotion of Field Studies has established a centre at Dale Head, inside the northern entrance to Milford Haven.

The region falls naturally into an upland northern section of older rocks and a lowland southern section of somewhat newer rocks. In the north the rocks range from Precambrian near St. David's to the Ordovician and Silurian, forming the mass of the Prescelly Hills. The general strike of the beds is southwest to northeast. From the Carmarthenshire border westward the rocks of the northern section of the county become older and older—Silurian, Ordovician, Cambrian, and finally Precambrian granitic and volcanic rocks near St. David's. As the rocks get older to the west, the elevation of the hills becomes reduced, terminating on the coast in numerous headlands, islands, and bays.

The rocks of the north and west are interspersed with igneous material such as the gabbros and diabases of Strumble Head, Fishguard, Llanwnda, and Prescelly; diorites northwest of St. David's, bostonites and porphyrites about Abercastle, and the basaltic laccolite of Pen Caer, besides various contemporaneous acid lavas and tuffs. The Ordovician and Silurian rocks extend southward to the neighbourhood of Narberth and Haverfordwest. Silver-bearing lead has been mined at Llanfrynach. The southern plain is open to the sea and may be looked upon geologically as a continuation westward of the south Wales coalfield, with associated Lower Carboniferous, Old Red Sandstone, and narrow belts of Silurian rocks, the whole having been considerably folded and faulted, producing a general northwest to southeast strike. The Coal Measures, highly inclined and anthracitic, stretch across from Carmarthen Bay to the shore of St. Bride's Bay; they are bordered on the north and southeast by the Millstone Grits, Carboniferous Limestone series, and Old Red Sandstone. Because of folding, the limestone appears again farther south of Pembroke, Caldy Island, and St. Gowan's Head, most of the remaining ground about Milford Haven being occupied by Old Red Sandstone with infolded strips of Silurian.

Antiquities, History, and Architecture.—The outstanding feature of the early history of Pembrokeshire is its importance in Megalithic times. The northwestern section of the county (including the southern slopes of the Prescelly Hills) is especially rich in Megalithic remains—dolmens, alignments, standing stones, and stone circles. There are similar remains in the southern half of the county but they are not nearly so marked, as a group, as in the northwestern district. This wealth of Megalithic remains suggests that northwest Pembrokeshire had cultural relations with many of the northwest coastal promontories of Europe in the days when metal was beginning to be known in the West.

Interest in the Stone Circle culture in Pembrokeshire was increased when it was shown that the stones forming the inner circle at Stonehenge (*q.v.*) were derived from rocks in Pembrokeshire. There are the well-preserved dolmens of the Longhouse near Mathry and the Pentre Evan near Newport. The stone circle known as Parc-y-Marw near Fishguard is also well preserved.

The number of hilltop camps, presumably of Romano-British type and date, is important, especially guarding ways in from the coast, though actual Roman influence in the county, which was originally within the territory of the Demetae, is slight. It is probable that the hilltop camps continued to be occupied through the post-Roman centuries as the county suffered from raiders from over the seas. In Pembrokeshire, as in Ireland, the native cultures lived on uninterrupted by Roman influences, and Pembrokeshire was apparently invaded by the Irish Deisi about A.D. 270. In those early centuries the county maintained its contacts with Ireland and Brittany and became a great centre of Celtic Christianity. Memorials of that period remain in the numerous church dedications and in the beautiful Celtic crosses such as those of Carew, Penally, and Nevern. Stones with Ogham inscriptions were found at Caldy Island, Bridell, St. Dogmaels, Nevern, Cilgerran, and other places.

The route that had linked Ireland, Pembrokeshire, Cornwall, Brittany, and northwestern Spain in Megalithic times became the route of the Celtic saints and, in the Middle Ages, an important pilgrim's way to the shrine of Santiago de Compostela in northwestern Spain (*see* A. Hartwell Jones, *Y Cymmrodor,* 1912). In a sheltered valley, at a focus of roads from small landing places on

the northwest coast of Pembrokeshire, was built the great Cathedral of St. David's (*q.v.*), soon to become a centre of pilgrimage, and at the landing places were built chapels for the pilgrims.

Pembrokeshire was known to the Welsh in those early times as Dyfed. On the death of Rhodri Mawr in 877, Dyfed fell nominally under the sway of the princes of Deheubarth, or south Wales; their hold was never very secure, nor were they able to protect the coast towns from the Scandinavian pirates. This is shown by the large number of Scandinavian place-names found in the coastal districts, especially near the southern coast. In 1092 Arnulf de Montgomery, son of Roger, earl of Shrewsbury, did homage to the king for the Welsh lands of Dyfed. With the building of Pembroke Castle, the Normans began to spread over southern Dyfed, while about the turn of the 12th century William Fitz Martin built Newport Castle, which became the *caput* of his extensive lordship of Kemes (Cemaes) between the Teifi River and the Prescelly Hills. Flemish settlers were planted in the hundred of Rhos, or Rhoose, in or about the years 1106, 1108, and 1111 with the approval of Henry I, and again in 1156 under Henry II. The castles of Haverfordwest and Tenby were erected to protect these aliens, and despite the fierce attacks of the Welsh princes their domain grew and their district became known as "Little England beyond Wales." In 1138 Gilbert de Clare was created 1st earl of Pembroke with the full powers of an earl palatine in Dyfed.

Examination of the medieval record shows a marked contrast between the *Englishery* of the south, with its compact villages and cultivation, and the *Welshery* of the north, with its scattered farms and tribal groups. The south was better populated than the north and maintained a closer contact with the affairs of the English plain; it was also the Norman stronghold and has long been famous for its medieval castles. The finest examples are to be observed at Pembroke; Manorbier, built in the 12th century and interesting as the birthplace and home of Giraldus Cambrensis; Carew, exhibiting many interesting features of both Norman and Tudor architecture; and Picton. Other castles are the keep of Haverfordwest and the fortresses at Narberth, Tenby, Newport, Wiston, Benton, Upton, and Cilgerran. There are remains of monastic houses at Tenby and Pembroke, but the most important religious communities were the priory of the Augustinian friars at Haverfordwest and the abbey of the Benedictines at St. Dogmaels. The latter, founded by Robert Fitz Martin in the 12th century, owned the priories of Pill and Caldy. Extensive ruins of the abbey exist near the left bank of the Teifi about one mile below Cardigan. Of the ancient preceptory of the Knights of St. John at Slebech scarcely a trace remains, but of the College of St. Mary at St. David's, founded by Bishop Houghton in 1377, the shell of the chapel survives.

Interesting examples of medieval domestic architecture are the ruins of the former episcopal mansions at Llawhaden, St. David's, and Lamphey, the two latter of which were erected by Bishop Gower between the years 1328 and 1347. The cathedral at St. David's is the greatest ecclesiastical monument in the county as well as in the principality. The nave dates largely from 1180–98, and the building was continued into the 13th century, added to in the 14th and 16th centuries, and restored in the 19th century.

The earldom of Pembroke was formally established as a shire by Henry VIII in 1536 and English law was imposed from 1542. Some parts of the county were for the king in the 17th century, though the influence of the Parliament grew as the castles of Tenby and Haverfordwest fell to the Parliamentary forces.

Population and Administration.—The administrative area of the county is 614.3 sq.mi. and the population in 1961 was 93,980. The municipal boroughs are Haverfordwest (pop. [1961] 8,872), Pembroke (12,737), and Tenby (4,752). There are four urban and four rural districts. The hamlet of Bridgend (*q.v.*) and a part of St. Dogmaels Parish are within the municipal limits of Cardigan. Newport (Trefdraeth), once the chief town of the barony of Kemes or Cemaes, was incorporated by Sir Nicholas Fitz Martin (*c.* 1210–82). Pembrokeshire has one court of quarter sessions and eight petty sessional divisions. It lies in the Wales and Chester circuit. From 1918 the county returned one member to Parliament. It is in the diocese of St. David's.

The Economy.—The county is mainly agricultural. Milk production is particularly important and there is a milk processing factory at Merlin's Bridge, Haverfordwest. The north is devoted more to storing cattle, while the Prescelly Hills are used chiefly for sheep rearing. Crops, grass, and rough grazings cover about four-fifths of the county, oats, wheat, and potatoes being the main crops. Early potatoes and turkeys are among the special products for which Pembrokeshire is well known.

Milford Haven (*q.v.*) is a deep-sea fishing port and also since 1960 a major oil port. In 1960 an oil refinery was constructed on the northern shore of the waterway to process about 5,000,000 tons of crude oil a year, and at another site a terminal was built for the yearly importation of a further 5,000,000 tons of crude oil to be pumped through a 60-mi. (97 km.) pipeline to a refinery at Llandarcy (Swansea). In 1964 another refinery was completed on the southern shore. In the same year plans were announced for a further refinery on the northern shore, a large oil-fired power station, and a bridge across the Haven near Pembroke Dock. The Milford Haven waterway is one of the finest natural harbours in the world.

Prior to the introduction of the new oil activities, industries were relatively small and mostly connected with agriculture, although some shipbuilding and repairing is carried on at Pembroke Dock and at Milford Haven. These two towns are the main industrial areas of the county. In 1958 the control of navigation was made the responsibility of a newly established Milford Haven Conservancy Board. Fishguard, on the north coast, is the port for passenger steamers to Rosslare in the Republic of Ireland. Since World War II Pembrokeshire has become increasingly popular as a tourist area, the chief centres of attraction being Tenby (*q.v.*) and smaller places around the coast such as Broad Haven, Little Haven, Newport, St. David's, Saundersfoot, and Solva. In 1952 the Pembrokeshire Coast National Park was established, comprising, as well as the coast itself, some inland areas covering 225 sq.mi. or about one-third of the county. In 1963 the National Trust owned 1,500 ac. and protected 2,397 ac. Skomer Island is a national nature reserve.

PEMMICAN, a North American Indian (Cree) word for "journey meat" prepared in such a way as to contain a maximum of nourishment in a minimum of bulk. Thin slices of lean bison or venison were dried in the sun and then pounded to a powder, seasoned, blended with equal parts of melted fat, and packed in rawhide bags. The food thus prepared could be easily transported, kept indefinitely, and could be eaten without cooking. It could also be dissolved in a gruel, and berries or dried fruit could be added. Pemmican was adopted by Europeans, especially the French-Canadian *voyageurs*, for whom it sometimes formed the principal diet. A form of pemmican made from beef continued to be used by explorers into the early 20th century, when foods preserved by modern methods superseded it. (R. W. HD.)

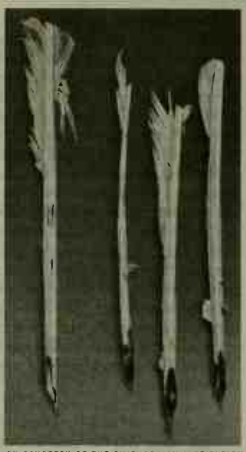
PEMPHIGUS: *see* SKIN, DISEASES OF.

PEN, an instrument for writing or for forming lines with ink or other coloured fluid. Although brushes, reeds, bird feathers and other materials have been used for making pens, there are only three modern types: (1) steel pen nibs; (2) fountain pens; and (3) ball-point pens.

Early Types.—The earliest writing implement probably was the brush, which the Chinese used in recording the history of their nation. The Egyptians made a reed pen from the calamus or arundo plants; hollow joints of bamboo also were used. A specific allusion to the quill pen occurs in the 7th-century writings of St. Isidore of Seville, but the quill pen probably was in use at an even earlier date. Quills were the main writing instrument until the middle of the 19th century and are still used occasionally (*see* FEATHER: *General: Uses of Feathers by Man*).

In 1809 Joseph Bramah of England devised and patented a ma-

chine for cutting the quill into separate nibs (points) that were slipped onto a holder for writing. In 1822 J. I. Hawkins and S. Mordan patented the use of horn and tortoise shell in making pen nibs, the points of which were made durable by small pieces of diamond, ruby or other very hard substance, or by lapping a small piece of thin sheet gold over the end of the tortoise shell.



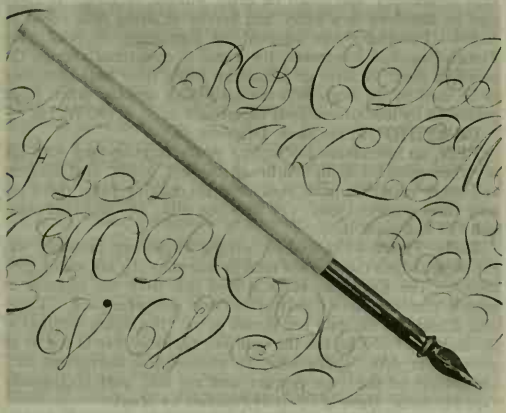
BY COURTESY OF THE SMITHSONIAN INSTITUTION

EARLY 19TH-CENTURY QUILL PENS FROM CONNECTICUT

Steel Pen Nibs.—Metallic pens, although known since the days of Pompeii, were little used until the 19th century and did not become common until near the middle of that century. Steel pens were handmade in France as early as 1748 and a Birmingham, Eng., split-ring manufacturer, Samuel Harrison, made a steel pen by hand for Joseph Priestley in 1780. Steel pens made and sold in London by a man named Wise in 1803 were of a tube or barrel design; the edges met to form the slit, while the sides were cut away as in the quill. In 1809 a patent was granted in the United States to Peregrine White on the slitting of metallic pens; these units also were handmade. Ordinary points were relatively expensive (about five shillings each) and, since they were hard, stiff and unsatisfactory, they were not in great demand.

John Mitchell of Birmingham, Eng., introduced machine-made pens in 1828, and James Perry is believed to have made the first steel slip pens. In 1830 Perry patented a design that provided greater flexibility because of a hole placed above the slit and branch slits cut on each side of the central slit. In 1831 an improvement consisting of an elongated point on the nib was described by Joseph Gillott. Steel pen nibs, after their retail price was reduced and they became available in various styles of point widths and flexibilities, soon became more popular than the quill.

In the early days steel pens were manufactured from rolled sheets of high-quality cast steel made from Swedish charcoal iron. These sheets, after being cut into strips of suitable width, annealed in a muffle furnace and pickled in a bath of sulfuric acid to free the surface from oxidized scale, were rolled between steel rollers until they were reduced to ribbons about $\frac{1}{140}$ in. thick. From these ribbons the pen blanks were punched out and after being imprinted with the name of the maker or embossed with other marks they were pierced with the central perforation and the side or shoulder slits. After another annealing the blanks, which up to this point had been flat, were raised or rounded between dies into a semicylindrical shape. The next process was to harden and temper the pens by heating them in iron boxes in a muffle furnace, plunging them in oil and then reheating them over a fire in a rotating cylindrical vessel till their surfaces attained the dull-blue tint characteristic of spring steel. Subsequently they were scoured in a bath of dilute sulfuric acid and polished in a revolving cylinder. The points were then ground with emery and the central slit was cut by two fine-edged cutters. Finally the pens were polished again and coloured by being heated over a fire in a rotating cylinder and in most cases were coated with a varnish of shellac dissolved in alcohol.



STEEL PEN NIB WITH WOODEN HOLDER

In the modern process long coils of high-carbon pen steel (equivalent to watch spring steel) are produced in the steel mills for the various manufacturers. Use of this type of steel made possible the employment of high-speed automatic presses in the various blanking, piercing, marking, forming, grinding and slitting operations. These coils are available in many thicknesses from less than that of a sheet of paper (.0020 in.) for making superfine mapping pens to .0150 in. for very rigid points used in carbon and manifold work. Modern methods also utilize completely automatic and atmosphere-controlled furnaces that eliminate the need for scouring. Increasing quantities of pens are plated with metal alloys that give them a silverlike finish and increased resistance to the ink acids and atmospheric conditions.

The first steel pen company in the U.S. was established at Camden, N.J., by Richard Esterbrook, Jr., in 1858, but local manufacturing did not begin there till early in 1861. Five craftsmen were brought from Birmingham, Eng., three of whom had worked for John Mitchell. Although Birmingham was the principal centre of the industry for many years, the U.S. company eventually became the largest producer of steel pens in the world. After World War I other companies began manufacture in the Camden area and the centre of production shifted there from Birmingham.

Metals other than steel—gold, silver, zinc, nickel silver, brass, aluminum, aluminum bronze and titanium—have been suggested in the making of nibs. In 1926 pens made from stainless steel were introduced; these pens are highly resistant to the acids and alkalies in writing inks and do not tarnish under extreme climatic conditions. (E. B. Ha.)

Fountain Pens.—In this pen a quantity of writing fluid is contained in a reservoir in a holder, the fluid communicating with the writing point or nib through a series of capillary channels called a feed. The nib extends from one end of the holder and is covered with a cap when the fountain pen is not in use.

Although crude prototypes were introduced much earlier, the fountain pen did not become popular until L. E. Waterman of New York introduced the first practical fountain pen in 1884. After that time millions of fountain pens were produced and sold each year.

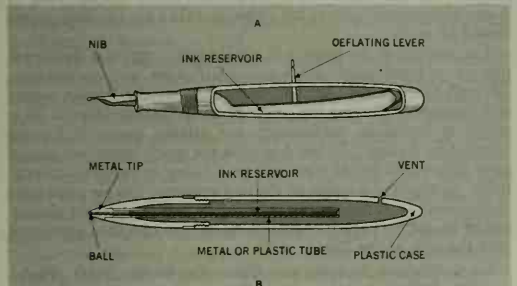
The writing point of the fountain pen is generally made in various point gradations ranging from a needlelike point to one that produces a line about $\frac{1}{16}$ in. in width. About 90% of the nibs sold are in the fine and medium gradations. A full assortment includes the following types: accountants, extra fine, shorthand, fine, medium coarse, stub, broad stub, italic stub, left oblique, right oblique and music points. Nibs also are produced in various degrees of flexibility ranging from manifold to flexible, the manifold being a rigid point and the flexible one bending with the least amount of pressure for shaded writing such as the copperplate or Spencerian forms of penmanship. In the 1930s a fountain pen with a detachable, renewable point was introduced.

Because of the expected long life of a fountain pen, a metal highly resistant to the corrosive action of writing fluids is used for the nibs; the most popular metals for points are stainless steel and 14-carat gold. Because these materials are relatively soft, the portion of the nib that contacts the writing surface is provided with a relatively hard tipping material, *e.g.*, an alloy of metals of the platinum group, in order to resist wear and thus obtain a long life.

The feed for controlling the movement of the writing fluid is made of plastic or hard rubber and underlies and, in most instances, supports the nib. Air and writing-fluid channels in the feed communicate between the reservoir in the holder and the nib, fluid from the reservoir moving down the fluid channels to supply the nib as air moves up the air channel to take the place of the fluid in the reservoir. These channels are of capillary dimensions, and the balance of pressures outside and inside the reservoir holds the fluid in the reservoir and overcomes the force of gravity. This balance is broken in writing when the cells of the paper or other writing surface draw fluid from the slit in the nib, the slit being supplied from the fluid channel of the feed.

Since the reservoir is seldom completely full of fluid, it frequently contains air. Changes in temperature and air pressure cause the air in the reservoir to expand or contract; some pens are equipped with threaded caps that offset these effects by creating an air seal. Care should be exercised when releasing the seal under extreme conditions of temperature or pressure; *e.g.*, at high altitudes the ink may run out of the reservoir because of the reduced air pressure. In all normal circumstances when the pen is held in a writing position, the air is behind the fluid and helps force it out of the reservoir. Comb cuts in the feed accommodate excess fluid. Continued writing uses the oversupply in the comb cuts before fluid again is drawn from the reservoir.

The filling of the reservoir, which was performed manually with an eye dropper in early fountain pens, is done in several different ways in modern pens. The flexible rubber-sac type of reservoir is deflated mechanically or pneumatically; upon release of the deflating means (*e.g.*, a lever), the sac inflates because of its own resiliency and fills by suction when the nib is immersed in writing



(A) CUTAWAY VIEW OF FOUNTAIN PEN WITH LEVER IN POSITION FOR FILLING INK SAC; (B) CROSS SECTION OF A BASIC BALL-POINT PEN

fluid. In another common type the bore of the holder is the reservoir and the movement of a piston fitted to the bore creates a suction that fills the bore as the nib is immersed in writing fluid.

Also in use are plastic ink-filled cartridges that can be discarded when emptied. When a cartridge is placed in the holder and screwed into place, a bore pierces the cartridge and forms a channel for the ink to flow to the nib.

The holder, once made of vulcanized rubber, is now usually made of a plastic. The plastic materials are structurally stronger than rubber. Several plastics are used, depending on the quality of the product or the facilities of the manufacturer. The plastic holders at first were drilled from solid rods. Later they were wrapped into cylindrical form from sheet material and still later were molded from plastic molding powders.

Ball-Point Pens.—In this type of pen a ball housed within a socket in the tip transfers a viscous ink from a reservoir onto the writing surface. Patents on ball-point pens date back to the late 1800s; commercial models appeared as early as 1895. The first workable ball-point pen was patented in 1937 by Laszlo Jozsef Biro, a Hungarian living in Argentina. His pen became popular in Great Britain during 1938 and 1939, and by about 1944 the ball-point pen had gained world-wide acceptance. The impetus for acceptance in the U.S. was supplied by the quartermaster general of the U.S. army, who had requested a writing instrument that would not leak in high altitudes, would use a quick-drying ink unaffected by climatic changes and would contain a supply of ink large enough to last a considerable length of time.

The ball-point pen usually comprises a holder for containing a replaceable writing unit, although in some models the holder itself is the writing unit and is discarded after the ink is used up. In all cases the writing unit consists of a metal tip having at the point a socket that contains a ball. The lip of the socket is constructed so that the ball cannot fall out yet can rotate freely when in contact with the writing surface. The inner construction of the socket is such that the ball is constantly bathed in ink from a reservoir.

Ball-point-pen inks are highly specialized materials. They are viscous liquids having either oil- or spirit-soluble dyes. The type of ink containing the oil-soluble dyes dries by absorption into the paper or other writing surface, while the type of ink containing the spirit-soluble dyes dries by evaporation.

The ink reservoirs of ball-point pens are of two types. One comprises a flexible, synthetic resin sac housed in a metal shell and the other a metal or plastic rigid tube, one end of which is open and is attached to the writing tip. The ink capacity of ball-point-pen reservoirs generally ranges from 0.5 to 1.5 ml. The tube of the 0.5-ml. reservoir is open at both ends; the viscosity of the ink prevents its leaking out. The 1.5-ml. reservoirs, however, require a vented plug and the use of a second more solid but still viscous material known as a follower. The follower is solid enough to prevent back-end leakage but is liquid enough to follow the ink down the tube as it is used.

At one time most of the balls used were steel ball bearings; in some instances synthetic sapphire balls were used. Later, tungsten carbide became the major material in high-quality ball-point pens. Most manufacturers use a ball 1 mm. in diameter, although a few special-purpose pens use larger or smaller balls.

PENANCE, that repentance or sorrow for sins which in the Christian revelation is a requisite for salvation: "Unless you repent, you will all perish" (Luke 8: 5). In Roman Catholic usage penance has a threefold meaning: first, interior repentance, a disposition of mind and will which includes both sorrow for past sins and a purpose of amendment for the future; second, the sacrament of penance, a religious rite in which, after confession of sins and an act of interior penance, the sinner receives divine forgiveness through the absolution of the priest; finally, the word designates penitential works, either those imposed on the penitent by the priest in the sacramental rite, or those performed voluntarily by a repentant sinner, as a form of satisfaction to God for past sins and a manifestation of interior repentance. *See* CONFESSION; SACRAMENT: *see* also references under "Penance" in the Index.

PENANG, the name of an island and of one of the Malayan states within the federation of Malaysia. The island lies off the northwest coast of Malaya, separated by a strait whose smallest width is 2½ mi. (4 km.). Its area is about 113 sq.mi. (293 sq.km.) and it is tortoise shaped, with a granitic, mountainous interior (highest point 2,428 ft. [740 m.]) and narrow coastal plains, most extensive in the northeast where Malaya's chief port, George Town (*q.v.*; often called Penang), uses the sheltered harbourage of the strait.

Since 1957 Penang Island together with Province Wellesley on the mainland has formed a state with an elected local government headed by a governor. The latter is appointed by the supreme ruler of the federation after consultation with the chief minister. The total area of the state is 398 sq.mi. (1,031 sq.km.) and the population (1961 est.) was 642,221. The state is the successor of a British colony founded in 1786 by Capt. Francis Light who secured an agreement from the sultan of Kedah to cede the territory to the East India Company. At that time the island, called Prince of Wales Island until after 1867, was virtually uninhabited and had ready access to Calcutta and Madras, with shelter and water for sailing vessels. It was also isolated from the restless, squabbling peoples on the mainland. Penang flourished as a port of call for shipping on the India–China run, quickly attracting a

cosmopolitan population of Chinese, Indians, Sumatrans, and Burmese, and rapidly surpassing any other trading post in western Malaya. From the mid-19th century Penang was a point of transit for immigrants to the mainland and a market for the tin miners of Perak, from which it developed into the chief port for the northern sector of the west Malayan tin and rubber belt. Malay influence, tradition, and economic life almost disappeared, and Penang remains predominantly Chinese by race and European in manner and economic outlook.

While the harbour was surpassed by Singapore, as the southern end of the peninsula was developed, Penang's decline was proportional rather than actual and it is still Malaya's chief outlet, usually handling twice as much oceangoing shipping as Port Swettenham and dealing with around one-fifth of the total Malayan seaborne trade. The island's rural population (39,000) grows vegetables and fruit for the urban market and there are rubber smallholdings in the foothills. A few Malays, both of immigrant Sumatran stock and from the peninsula, produce a little rice and fish, particularly toward Balik Pulau on the southwest. During the alternating seasons of northeast and southwest winds, the incidence of rain is affected by the "shadow" of the hilly interior. In George Town rainfall averages 105 in. annually with maxima in October and May, no month having less than 3 in. Mean monthly temperatures at the coast are 27° C (80° F) and the drop of about 6° F on the crest of Penang Hill attracts tourists, though, despite a cable railway to the top, nothing comparable to the hill stations of India has developed. A coast road about 75 mi. (121 km.) long encircles the island. An airport at Bayan Lepas on the southeast corner has domestic services to Kuala Lumpur and Kota Bharu and air links to Singapore, Medan in Sumatra, and Bangkok, Thailand.

Province Wellesley, the mainland part of Penang State, has a different character physically and economically and is continuous with the west Kedah plain on the one side and the tin and rubber belt on the other. It carries more than 35,000 ac. (14,100 ha.) of paddy worked by Malays, market gardening by Chinese farmers, and nearly 55,000 ac. (22,000 ha.) of rubber worked by Chinese and Indians. In area and population the mainland district is bigger than the island and has a productive rather than a trading economy. It exports about 6,000 tons of rubber annually from George Town and its 15,000 tons of rice are consumed locally. The shallow meandering streams, often flanked by nipa swamps, impede overland transport and the shallow waters hinder coastal approaches, a heavy longshore drift from the north tending to silt up the piers and harbour works; yet Province Wellesley is an important focus of land and sea transport for the overseas trade of Penang. Arterial roads from Kedah and Perak bring rubber, copra, and tin ore to Butterworth, the ferry point for George Town. South of Butterworth and separated from it by a muddy estuary is Prai, the terminus of a branch of the Malayan railway, which has its own passenger and goods ferry to Penang. From Prai, the railway runs inland to the market town of Bukit Mertajam from where the line runs north through Kedah to Thailand and south to Ipoh, Kuala Lumpur, and Singapore. Butterworth, though overshadowed by George Town, also has Malaya's chief oil-importing facilities and the most modern tin smelter. Butterworth and Prai are open settlements and tend to merge; they are dominated by Chinese and Tamils, though the province has a large Malay rural population. (E. H. G. D.)

PENARTH, an urban district in Glamorgan, south Wales, is situated around a promontory about 200 ft. (61 m.) above sea level, 5¼ mi. (8½ km.) S of Cardiff by road. Pop. (1961) 20,897. Bounded on the east by the Bristol Channel, the headland is dominated by the saddleback tower of St. Augustine's Church, a well-known landmark for sailors. The Turner House Art Gallery exhibits art collections of the National Museum of Wales.

Penarth is a popular seaside and residential town with well-laid-out parks and treelined streets, pier, and esplanade. Pleasure steamers provide a frequent service to Bristol Channel resorts. Air services operate from Cardiff (Rhoose) Airport.

Local industries include the production of precast concrete products, bricks, and wood joinery. (H. M. Jo.)

PENATES, the household gods of the Romans and other Latin peoples, more properly *di penates*. Strictly speaking they were gods of the *penus*, "storeroom," or the *penetralia*, the innermost part of the house, but by extension their protection reached the entire household. They are associated with other deities of the house: Vesta (*q.v.*), the goddess of the hearth, and particularly the lares (*q.v.*), with whom they are often named interchangeably. They cannot be identical, however, for the penates, unlike the lares, are never referred to in the singular. The penates are thus all or some specific group of deities with household connections. Their number and precise identity were a puzzle even to the ancients. Thus Jupiter, Juno, Minerva, Neptune, Apollo, and others (besides Vesta and the lares) are reckoned at times among their number.

The penates were worshiped privately as protectors of the individual household and also publicly as protectors of the Roman state. Each house had a shrine, however simple, with images of them that were worshiped at the family meal and on such personal occasions as birthdays and other anniversaries of special events. Offerings were of portions of the regular meal or of special cakes, wine, honey, incense, and more rarely a blood sacrifice. The state as a whole worshiped them as the *penates publici*, about whom there were various opinions of nature and origin. There was a tradition connecting them with the "great gods" of the Samothracians (*see* CABEIRI) as well as the tradition, followed by Virgil in the *Aeneid*, that Aeneas brought them from Troy. A conflation of these two has the Samothracian deities introduced first at Troy and subsequently brought by Aeneas to Latium. The connection with the Cabeiri explains their further association with Castor and Pollux (*q.v.*), with whom they were popularly assumed to be identical. Indeed, their cult statue in the temple on the Velia in Rome represented them as the twins, and they are similarly represented on coins.

The worship of the penates in a state cult occupied a significant role as a focal point of Roman patriotism and nationalism. Through the republic the chief magistrates of the Roman people and commanders taking the field offered special sacrifices at their shrine at Lavinium, traditionally the original shrine in Latium founded by Aeneas. In the Augustan era much stress was placed upon the revival of the state cult as a factor in creating national unity, loyalty, and support of the new regime. The personal gods of the house of Augustus (*i.e.*, the Julian *gens*, which had already traced its origins back to Aeneas himself) became thus associated with the gods of the Roman state.

See G. Wissowa, *Religion und Kultus der Römer* (1912); Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft.* (R. B. Ld.)

PEN-CH'I (also known as PENKI), industrial centre of Liaoning province, China, in southern Manchuria, 40 mi. (64 km.) SE of Mukden, on the railroad leading to North Korea. Pen-ch'i, originally known as Penchihu or Penhsihu, is a steel-smelting centre based on local coking-coal and iron-ore deposits. The steel plant was founded in 1915 as a mixed Chinese-Japanese enterprise but passed subsequently to full Japanese control. Pen-ch'i iron ore, mined south of the city, is low in phosphorus and sulfur and is suitable for special steels, which are smelted at Pen-ch'i in Bessemer converters and electric furnaces. Coking coal is mined along the valley of the T'ai-tzu Ho east of the city. Pen-ch'i also produces cement and refractories. In the 1953 census, when the city limits included the iron- and coal-mining districts, the population of Pen-ch'i was 449,000. (T. Sp.)

PENCIL, a solid rod of graphite or other marking material enclosed in a wooden case or other type of holder and used primarily for writing or drawing.

History.—During the Middle Ages paper was marked with inks using a brush called a *penicillus* (Latin for "little tail"), from which comes "pencil." *Pinsel* in modern German means a "brush" and has never been used for lead pencil; the German *Bleistift* for "pencil" translates literally as "lead pin," or "lead pencil." A rod made of lead and tin alloy and called a silverpoint tool (*see* PENCIL DRAWING) was used by Albrecht Dürer in the early 16th century; marks made with this instrument were erased with bread.

Konrad von Gesner in *De omni rerum fossilium genere* (1565) first described a writing article in which graphite was inserted into a wooden holder.

The modern lead pencil was made possible by the discovery in 1564 of an unusually pure deposit of graphite (*q.v.*) in Borrowdale, Cumberland, Eng. According to tradition, the mine was found when a large oak tree was uprooted by a storm. Graphite was then thought to be a type of lead and consequently was called black lead or plumbago. Gesner was the first to describe it as a separate mineral, calling it *stimmi anglicanum*, or English antimony. Carl Wilhelm Scheele in 1779 showed it was a form of carbon, and Abraham G. Werner in 1789 gave it the name graphite, based on the Greek *graphein*, "to write."

The black lead from Borrowdale was first used in chunks called marking stones; later, shaped sticks of the graphite were wrapped with string and unwound from one end as needed. Pieces were also pushed into tubes and later were held in the claws of metal holders called *porte-crayons*, or portcrayons; these were the forerunners of the mechanical (propelling) pencil.

Graphite from the Borrowdale mine, which was operated as a crown monopoly, was of such high quality that as long as the supply lasted it could be used in its native condition. However, as the graphite became scarcer, methods were sought for binding graphite dust into usable shapes with gums, resins, glue and other adhesives. Later, natural graphites were discovered in Bavaria, Mexico, Madagascar, Ceylon and Korea. The first graphite composition pencil was made at Nürnberg, Ger., in 1662, where Kaspar Faber (*see* FABER) established his pencil-making business in 1761. The mixture that came closest to matching the writing qualities of pure graphite consisted of one part sulfur to two parts graphite. Graphite shapes glued to fir or cedar were described by J. Pettus in 1683; manufacture of this type of pencil was begun in Britain by T. and R. Rowney in 1789.

Late in the 18th century, when imports into France were cut off by warfare, Napoleon Bonaparte commissioned Nicolas Jacques Conté (*q.v.*) to develop a substitute for imported pencils. In January 1795 a French patent was issued to Conté for a pencil lead-manufacturing process that was the forerunner of the modern process. He mixed clay and graphite with water and pressed the paste into grooves in wood to dry. The dried leads were then baked in a kiln to fire the clay. In Vienna at about the same time, Joseph Hardtmuth achieved the same results and by varying the clay content varied the hardness of the leads. In 1839 Johann Lothar von Faber of Nürnberg improved the Conté process by extruding the paste through a die and introducing machinery that cut and grooved the wooden slats that enclosed the leads to form a pencil.

The first copying lead was made by Karl Puscher in 1857. Leads of this type contain a dyestuff and are not fired.

In the United States Joseph Dixon (*q.v.*) started manufacturing pencils at Salem, Mass., in 1827. A man named Wood, the associate of another early manufacturer, William Monroe, is credited with using the first machinery to manufacture pencils. In 1876 Dixon's company introduced lead with a round, rather than square, cross section. Meanwhile, in Britain, varnished pencils were introduced by George Rowney and Co. in 1846.

In the 1930s methods were developed for bonding the lead securely to the wood casing and thereby increasing the resistance to point breaking.

Erasers.—The *Proceedings* of the French Academy for the year 1752 reported that a man named Magellan proposed the use of caoutchouc as a replacement for bread crumbs in erasing black lead marks. Joseph Priestley, the English chemist, is credited with applying the name "rubber" to caoutchouc in 1770 since it was being used to rub out marks. The modern eraser is essentially a mixture of vulcanized vegetable oil (factice), fine pumice and sulfur bonded with rubber. The mix is processed, extruded and vulcanized in rubber-processing equipment. The first patent on an integral pencil and eraser (U.S. pat. no. 19783) was issued to Joseph Rechendorfer of New York on March 30, 1858.

Mechanical Pencils.—Mordan and Hawkins have been credited with introducing the mechanical pencil in 1822. Alonzo T. Cross made a mechanical pencil in 1868 and a mechanical pencil holding a lead of large diameter was patented June 26, 1877. The lead in the 1877 invention was held by spring-loaded jaws on a principle similar to that used in modern pencil holders used by draftsmen. Mechanical holders in which small-diameter leads were propelled by twisting the body appeared in 1895. The leads were of various diameters at first but eventually leads 0.046 in. in diameter became more or less standard. In 1938 lead 0.036 in. in diameter was introduced. In the 1950s ball-point pencils became available; these differed from ball-point pens in that the marking could be erased.

The use of mechanical holders for drafting leads was increasing in the second half of the 20th century and the screw-tightened chuck largely gave way to spring-loaded jaws, which were operated by pushing the top of the holder. While many patents have been granted on mechanical pencils, the two most popular designs have been: (1) the split collet type, in which the lead is propelled by a screw; and (2) the propel-repel-expel type, in which the lead is forced at the top end into a split cup that is moved forward and backward by a screw while the lead protrudes loosely through a bored tip at the writing end.

Coloured Leads.—Coloured leads are made with either water-soluble or water-insoluble pigments. Both kinds of lead are essentially a mixture of colouring material, filler, lubricant and binder. The filler frequently is clay or talc, the lubricant is a fatty acid and/or a wax or waxlike material and the binder is either a natural gum (*e.g.*, tragacanth), a man-made gum or a cellulose ether (synthetic resins also are used to a limited extent). The function of the binder is to give mechanical strength. Copying leads are made of pigment and binder, while indelible leads are essentially methyl violet, graphite and binder. The general practice is to make a well-mixed dough of the ingredients, extrude the lead through a die and dry the wet strands.

Method of Manufacture.—The method generally used in the manufacture of black lead pencils is as follows:

Ball clay and natural graphites (sometimes wet-ground together) are thoroughly mixed with water and dispersing agents to produce a stiff dough. The mass is packed solidly into the cylinder of an extrusion press and the dough is forced through a small hole in a die made from diamond, sapphire, agate or cemented carbide. The tough, pliable, wet strands are cut to pencil length, dried and then fired while packed in a sagger in a kiln. Firing temperatures from 1,600° to 2,200° F. (about 871° to 1,204° C.) are used, with 1,900° to 2,000° F. (about 1,037° to 1,093° C.) being commonest. The brittle fired leads are then "waxed" by being impregnated with a lubricant (usually a mixture of fats and fatty acids with or without wax additions). After chemical treatment to remove excess wax from their surface, the leads are ready to be encased in the wooden sheath.

Leads to be used in wood casings are customarily extruded with diameters of between .070 and .170 in.; the softer leads are made with the larger diameters to offset their weaker strength and their greater rate of wear. Leads for mechanical pencils are usually extruded in diameters of .036 or .046 in.

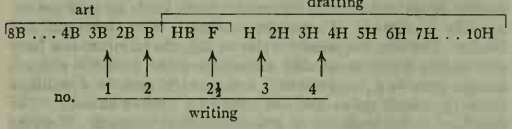
Wooden pencils are manufactured in an assembly operation. Two to nine parallel and evenly spaced semicircular grooves are cut in wooden slats that are 184 mm. long, 5 mm. thick and up to 65 mm. wide (about $7\frac{1}{4} \times \frac{1}{4} \times 2\frac{1}{2}$ in.). Leads of the same diameter as the grooves are sandwiched in the grooves of two matching slats, to which an adhesive has been applied, and the block is held under pressure until the adhesive sets. Hide glue was almost completely replaced with polyvinyl acetate emulsion adhesive in the 1940s. High-frequency electricity is sometimes used to set the glue rapidly (*i.e.*, in about 50 sec.).

The individual pencils are cut lengthwise from the glued blocks in high-speed rotary shaping machines; most pencils are either round or hexagonal with rounded edges. Pigmented nitrocellulose lacquers are then applied by pushing the pencils lengthwise through lacquer and wiping off the excess by passing the coated pencil lengthwise through a rubber gasket; the pencils fall on a moving belt, where they dry. From three to ten coats of lacquer are applied; the higher-quality pencils usually receive the most lacquer.

After the ends of the pencils are trimmed, the name and other identification is hot impressed from foil. If desired, a machine then tips the pencils by affixing a metal ferrule and an eraser plug on one end.

Quality and Hardness.—The quality of a wooden pencil depends chiefly on the quality and fineness of the graphites and clays used in the lead and on the quality of the cedar used to enclose the lead. Californian incense cedar (*Libocedrus decurrens*) is used in the better pencils; it has largely replaced red cedar (*Juniperus virginiana*) from Kenya and the eastern U.S., which was once used almost exclusively. The hardness of lead, which is independent of quality, is determined chiefly by the ratio of clay to graphite; the more clay, the harder the lead. The temperature of firing and the type of waxing exert a minor influence and must be controlled to attain uniformity of hardness in different batches.

Two systems are used for designating hardness. Drafting and artists' pencils range in designation from 8B, the softest, to 10H, the hardest. Hardness in writing pencils is designated by numbers ranging from 1 to 4; the range overlaps the ranges of both art and drafting pencils, which also overlap each other (*see* below).



The degree of hardness of a lead is a measure of how much the lead resists abrasion by the fibres of the paper being marked on; the greater the rate of wear, the softer the lead. The apparent blackness of the mark depends on the size of the small particles of the lead deposited on the paper. The particles are of the same blackness regardless of the degree of hardness; only their size and number determine how much of the paper will be obscured. The type of paper and the atmospheric humidity also influence the amount of lead abraded, as do the fineness of the lead point and the amount of writing pressure used.

Other Types of Pencils.—Many special types of pencils are made for special uses; *e.g.*, rectangular or square carpenter pencils whose shape facilitates marking with a guide and also prevents rolling if dropped. Another special pencil is the kind used for filling in blanks in examination answer sheets that are scored electrically; these leads conduct electricity. Other special pencils will mark on glass or can be used in offset printing. Yet others are made as cosmetics (*q.v.*).

See Clarence Fleming and A. L. Guptill, *The Pencil Since 1565* (1936); Erhard Sattmann, *Vom Faustkeil zum Bleistift* (1953).

(S. B. Se.)

PENCIL DRAWING. The common instrument used in pencil drawing is composed of graphite enclosed in a casing of wood (*see* Pencil). The cylindrical graphite pencil, because of its usefulness in easily producing linear gray-black strokes, became the successor of the older metallic drawing stylus with which late medieval and Renaissance artists and tradesmen sketched or wrote on paper, parchment or wood.

The silverpoint (silver stylus) was the favourite instrument for metal-point drawing or writing although styluses of lead or lead alloys were frequently used. Metal points containing lead could be used on the natural surface of paper or parchment, but the metal points of silver, gold, brass and bronze required that the drawing surface be covered with an applied ground. This ground, usually made with lead white and a binding solution of glue or gum arabic, was brushed over the surface and when dry provided the means by which the metallic tools produced strokes. The ground, either white or slightly tinted with the addition of a coloured pigment, in combination with the silverpoint provided a medium of very delicate and precise drawing. These characteristics, along with its fine linear effects, appealed to many of the great draftsmen of the late middle ages and Renaissance. Van Eyck, Dürer, Raphael and Leonardo were some of the outstanding masters who used the metal point antecedents of the graphite pencil.

The metal points of lead or lead alloys, because of the metallic reflections and slightly rougher texture of their dark gray strokes, were the most apparent forerunners of the pencil. This superficial similarity in the appearance of lead-point and graphite strokes led, in England, to an erroneous and widespread identification of the graphite pencil as a "lead pencil," a mistaken identification that is still common.

Although graphite was being mined as early as the 16th century, the utilization by artists of pieces of natural graphite, inserted in a *porte-crayon* (holder), has not been established in extant drawings produced before the 17th century. At that time minor graphite details were included in sketches, notably in landscape renderings by Dutch artists such as David Teniers the Younger and Aelbert Cuyp. During the 17th and most of the 18th century graphite served as a means of making preliminary sketch lines for drawings to be completed in other media. Exceptions were drawings completely finished with graphite, as in the case of a few 18th-century works by Thomas Gainsborough and George Romney.

Although pencil drawings were much less commonly produced by artists of those centuries than sketches in the preferred mediums of chalks, charcoal and pen and ink, the use of graphite gradually increased among painters, miniaturists, architects and designers. By the late 18th century an ancestor of the modern pencil was constructed in the form of a rod of natural graphite fitted into a hollow cylinder of wood. However, it was not until 1795, when Nicolas Jacques Conté devised his method of producing pencil rods from mixtures of graphite and clays, that a true prototype of the modern graphite pencil was developed. Conté's technical improvement made possible the production of fine pencils whose strokes could be controlled, varying from type to type in softness and hardness, darkness and lightness. The excellent quality of these graphite pencils encouraged wider use by artists of the 19th century, and pencil drawing was to become a common method for creating studies and preliminary sketches. The fact that the graphite pencil could be used on almost any type of drawing surface helped to make it an indispensable instrument of the artist's studio.

Although graphite pencils provided a substantial range of light-dark effects and the opportunity for tonal modeling, the greatest masters of pencil drawing always retained in their creations the elements of a simple linearism or limited shading that were appropriate to drawing in this medium. This concept of pencil drawing contrasted with that sometimes employed in the 18th and 19th centuries in which extensive tonal modeling of three-dimensional forms and elaborate effects of light and shade were produced by artists and miniaturists by rubbing the soft graphite particles with a stump, a tightly rolled piece of soft paper or chamois.

The preciseness and clarity associated with the use of a moderately hard graphite pencil were developed in the highly selective draftsmanship of the French neoclassicist Jean Auguste Dominique Ingres. His figure sketches and portrait studies were the epitome of a type of pencil drawing in which lucid contours and limited shading combined to create a spirit of elegance and restraint. This manner of drawing was accepted by many artists throughout Europe, including German draftsmen such as Ludwig Richter, who exhibited a preference for the hardest of pencils and sharpest of points in order to produce wirelike delineations of figures and landscapes. Softer and darker graphite pencils offered the possibility of appropriate effects to artists whose tastes required more freedom and spontaneity of drawing. The sketches of the romanticist Eugène Delacroix, created swiftly and filled with flamboyant and undetailed strokes, possessed a visual suggestiveness of dramatic figures and compositions. Van Gogh chose a broad carpenter's pencil for powerful, blunt strokes.

One of the most sensitive of those who used the graphite pencil in the 19th century was Edgar Degas. A master pastelist and draftsman with coloured chalks and charcoal, Degas created pencil drawings possessing warmth and charm that were quite unlike the cool, classic works of Ingres or the highly animated and sometimes violent sketches of Delacroix. Degas, with high selectivity, combined graciously fluid outlines with soft, limpid tonal shadings. In creating these effects he often employed more than a single

pencil in order to extend the range of softness or darkness in various parts of his figure studies.

Pencil drawing seems to have been a desirable medium for sculptors, and the sketches of Auguste Rodin, Aristide Maillol and others suggest the efficacy of the pencil for studies of contours and masses so important in sculptured figures and in the compositional grouping of sculptural forms.

Artists of the 20th century continue to use the graphite pencil as a device for sketching and for making preliminary rehearsals of conceptions later carried out in painting or sculpture. Because of the nature of much contemporary painting, there is less cause for artists to draw or preplan their paintings with the assistance of pencil studies; nevertheless, the function of drawing persists, and among many artists it is still considered an essential skill. Distinguished artists such as Henri Matisse, Amedeo Modigliani, Pablo Picasso and others, whose taste for basically linear conceptions was revealed in their graphic works, selected the graphite pencil as a device for creating lucid and simple images. *See also* DRAWING (TECHNIQUES OF); PEN DRAWING; PENCIL.

PENCK, ALBRECHT (1858–1945), German geographer and geologist, and the founder of Pleistocene stratigraphy, was born at Reudnitz near Leipzig on Sept. 25, 1858. He trained as a geologist and petrologist at the University of Leipzig. Through field work for the Geological Survey of Saxony he was led to the problem of Pleistocene glaciation. He began his academic career as a lecturer in geography at the University of Munich in 1883 with a thesis *Vergletscherung der deutschen Alpen* (1882) which opened a new epoch of Pleistocene research by combining stratigraphical and geomorphological observations. In 1885 he was appointed professor of geography at Vienna, and wrote his *Morphologie der Erdoberfläche* (two volumes, 1894), the first textbook on the subject. His main work with Eduard Brückner, *Die Alpen im Eiszeitalter* (three volumes, 1901–09), the result of comprehensive field research, confirmed the four phases of Pleistocene glaciation. In 1906 Penck took the chair of geography at the University of Berlin, where he was also director of the Institute of Oceanography. In 1908 he was Silliman lecturer at Yale University, and exchange professor at Columbia University with William Morris Davis in 1909. He originated and promoted the 1:1,000,000 map of the world. Travels in North America, east Asia, Australia, and southern Africa widened his knowledge in other fields of geography. He was a versatile organizer and for many years the most prominent figure of German geography. He survived his son Walter, a geologist, and his grandson Martin, also a promising geologist. He died in Prague on March 7, 1945.

(C. T. T.)

PENDA (d. 654), Anglo-Saxon king of the Mercians from 632, or soon after, until 654, son of Pybba, already in 628 led the Mercians in the Battle of Cirencester against the West Saxons and obtained the lands of the Hwicce (*q.v.*). He and Cadwallon of Wales destroyed Edwin of Northumbria in 632. Though he became subject to Northumbria in 633, he recovered independence when he killed its king Oswald in 641. Though not included in Bede's list of kings with dominion over all kingdoms south of the Humber, he was not far from holding such power. The areas corresponding to Cheshire, Shropshire, and Herefordshire were acquired, he made his son Peada subking of Middle Anglia by 653, he subdued East Anglia, killing its kings Sigeberht, Ecgric, and, about 653, Anna, and he drove out Coenwalh of Wessex for three years. In 654 he invaded Northumbria with forces drawn from many kingdoms, but was slain by Oswiu at the battle of the Winwaed. The statement in the Anglo-Saxon Chronicle that he was then 80 is proved false by the ages of his sons and relations. Though a pagan, he did not persecute Christians; his son Peada, and a daughter, married into the Christian royal house of Northumbria, and Peada introduced Christianity into Middle Anglia in Penda's reign.

(D. WK.)

PENDENTIVE, in architecture, a triangular segment of a spherical surface, filling in the upper corners of a square, rectangular, or polygonal room, in order to form, at the top, a circular support for a dome. Its intersections with the walls against which it abuts are semicircles, and are usually carried by arches. The problem of supporting a dome over a square or polygonal hall was of continually growing importance to the late imperial Roman builders. This they attempted to solve, either by corbelling out the corners, projecting each course of masonry slightly over the one below, or by throwing across the corner diagonal arches or niches, which are known as squinches (*q.v.*). An early approximation of the pendentive form occurs in a domed room in one of the side buildings of the baths of Caracalla (A.D. 217). This form, however, was obtained by corbelling, whereas the true pendentive is built like a portion of a dome with radiating joints. It remained for the Byzantine architects to recognize the possibilities of the form and give it definitive development. One of the earliest examples is also one of the largest—that of the great church of Hagia Sophia at Istanbul (begun 532). Pendentives occur commonly in the domed Romanesque churches of Aquitaine in France, as in S. Front at Perigueux (begun 1120). They occur spasmodically in Romanesque work in Italy. During the Renaissance the development of domed churches gave great importance to the pendentive. As a result of Byzantine influence, pendentives are frequent in Islamic architecture, often decorated with stalactite ornament or sometimes, as in Iran, with delicate ribbing. A vaulting form in which the curve of the pendentive and dome is continuous, without a break, is known as a pendentive dome.

See BYZANTINE ARCHITECTURE; DOME; ROMANESQUE ARCHITECTURE.

PEND OREILLE, a large, question-mark-shaped lake in northern Idaho, U.S., fed chiefly by the Clark Fork and drained by the Pend Oreille River. Noted for its rugged shore line and size (43.2 mi. long and 6.25 mi. wide), it covers 123 sq.mi. and a depth of 1,150 ft. has been recorded. Sport fishing for trout, including Kamloops, or Kootenay trout, which like steelheads are exceptionally large rainbows (up to 30 lb. or more), whitefish, and landlocked salmon is popular. The name, meaning "earbob," is believed to refer either to the shape of the lake surface (a pendant hanging from an ear) or to earrings worn by the local Indians. The first trading post in Idaho, Kullyspell House, was established by David Thompson at the mouth of the Clark Fork in 1809. Albeni Falls Dam, about 20 mi. below the lake on the Pend Oreille River, controls the water level of the lake.

(M. E. MS.)

PEN DRAWING. Pens have had the longest history and greatest popularity of all the drawing media of the artist. In part, this is the result of the variety of linear effects that can be provided by the three basic types of pens and of their adaptability to the changing styles of draftsmanship that have occurred over many centuries. These three basic types are: quill pens, cut from the wing feathers of fowls and birds; reed pens, formed and trimmed into proper shapes from stems of bamboolike grasses; and metal pens, fabricated from various metals, especially fine steel.

Pen drawing is fundamentally a linear method of image-making with the visual descriptions of the drawing being produced by a simple outline or a complex of ink strokes. In pure pen drawing where the artist wishes to supplement his outlines with tonal suggestions of three-dimensional form, this modeling must necessarily be effected by the close juxtaposition of a series of strokes forming areas of hatching or crosshatching. On the other hand, many pen studies are produced with the substitution of tonal washes laid onto the drawing with a brush, in which case the outlines or other important definitions of the figures or landscape are established by the pen lines.

Paper and Ink.—Pen drawing is usually done on papers expressly produced for this purpose. In the middle ages and the Renaissance parchment also was occasionally used. Although the pen was the instrument with which the artist distributed the delineating strokes in their desired arrangement on the paper, ink was the actual medium that made pen drawing possible. Inks used in

pen studies were of various types and contributed an additional diversity to the final effects in sketches. The prime requisites of inks for drawing were great fluidity as well as strong tinting power.

Three types of ink possessed these qualities and were most frequently chosen by the great masters of drawing. One was black carbon ink, made from extremely fine particles of the soot of burnt oils or resins incorporated into a solution of either glue or gum arabic. This ink retained its original blackness over long periods of time, and old drawings produced with it reveal lines as strong as when they were initially made. The finest type of black carbon ink was known as Chinese ink and was the prototype of the modern black India ink used by artists, architects, engineers and other draftsmen. A brown ink popular with the old masters was known as bistre. It was prepared by boiling wood soot in order to obtain the liquid and transparent brown extract. Many artists chose bistre for its warm, luminous colour qualities, and it was especially effective for the illusionistic drawings of 17th- and 18th-century masters, including Rembrandt and Giovanni Battista Tiepolo. The third important ink was an iron gall or chemical ink. Its principal ingredients were iron sulfate, the extract of gall nuts and a gum arabic solution. It was, in fact, the common writing ink for centuries and was employed for most early drawings. Its colour when first applied to the paper was bluish-black, but it rapidly turned blackish and, over the course of years, became a dull brown; the effect is commonly seen in old handscript letters and documents as well as old drawings. Other inks, usually coloured inks made from natural or synthetic dyestuffs, were used on rare occasions. Throughout the history of drawing, however, coloured inks were less favoured, and studies in which chromatic effects were introduced are exceptional.

Pens.—The oldest of the artist's pens was the reed, although its use in antiquity and in the middle ages was for writing; it was not employed for drawings until the Renaissance, when its fibrous structure and blunt point were found attractive to some draftsmen for creating simple, heavily linear drawings, as those by Luca Cambiaso, or for large drawings, as those by Odoardo Fialetti and Marco Boschini. The outstanding master of the reed pen was Rembrandt, who used it many times in combination with the quill pen and washes to produce the richly suggestive atmospheric illusionism of his works. His usual method was to introduce very bold strokes of a broadly cut reed in order to articulate forms within shadows, while the more illuminated parts of the drawing were indicated with delicate quill lines.

The reed pen never had the widespread popularity of quill or metal pens, but for special effects it served artists admirably. Vincent van Gogh in his last years used it to produce the blunt, powerful strokes that in his drawings were counterparts of the heavy brush strokes typical of many of his Expressionist canvases. Among modern artists the reed pen occasionally has been chosen because of the simple or vigorous strokes that it easily creates; Henri Matisse and George Grosz, both distinguished practitioners of drawing, selected the reed pen for strong linear elements falling halfway between those usually associated with a fine steel pen and a wide brush.

In the history of drawing as it developed in the western world, the quill pen made from the large, hollow wing feathers of the goose, swan or raven has served with the greatest distinction of all pens, and until the time of the acceptance of the modern steel pen there were few master draftsmen who did not engage in quill-pen drawing. Before the end of the middle ages, when papermaking was introduced into Europe, providing a relatively cheap material for sketches and other types of studies, the quill pen was used in making the fine delineations of images in manuscripts. Just as it was the best pen for the precise handscript lettering of the manuscripts, so also its nibs, which could be sharpened to extreme fineness, permitted the craftsman to create small linear figures or ornamental decorations on the pages or along the borders of the parchment leaves. Whereas the fibrous reed pen gave the sensation of being dragged over the paper, the delicately cut point of the quill pen glided over the surface and needed only to be guided by the hand of the artist to create a graceful and calligraphic type of drawing. This characteristic, combined with the flexibility of the quill point, which responded to pressure for varying the widths of lines or forming accents, made it adaptable to the diverse hands and personal styles of draftsmen. Moreover, its adaptability to artistic demands enabled the quill to meet the requirements of changes in style that took place from the 15th to the end of the 19th century. Whether the requirements were for highly controlled but restless vigour as in Albrecht Dürer's linearism, graceful contour drawing similar to that of Raphael, or spontaneous and suggestive strokes as in Rembrandt's studies, the quill served artists equally well.

In most respects the metal pen became the successor of the quill. Although pens of silver, bronze, brass and gold alloy had been tried in the past, it was the development of excellent steel pens by James Perry in the 1830s, and mass production by stamping pens from steel blanks, that led to the supplanting of the quill by the metal pen. Nevertheless, artists were reluctant to adopt the steel pen, even after its ready acceptance for writing, and most drawings in pen and ink done prior to the 20th century were still produced with quills.

Although contemporary artists on occasion select reed or quill pens for the handsome and diversified effects they provide in drawing, the steel pen now is used for drawing almost exclusively. This type of metal pen has its virtues both in its easy availability and in the great variety of shapes and sizes, stiffness or flexibility. Because of the crisp, incising type of line it can produce with modern black inks, it is especially appreciated by artists and draftsmen who execute drawings to be reproduced in books and periodicals. It has become standard studio equipment of the illustrator, cartoonist and designer. Pen drawings by outstanding painters and sculptors such as Pablo Picasso, Matisse and Henry Moore suggest the assistance the steel pen provides in producing the sharpness of linear definitions generally preferred by modern masters. *See* also DRAWING (TECHNIQUES OF); ENGRAVING, LINE; INK; PEN; PENCIL DRAWING.

PENELOPE, in the *Odyssey*, the wife of Odysseus and daughter of Icarius of Sparta and the nymph Periboea. During the course of the long absence of her husband after the fall of Troy many chieftains of Ithaca and the islands round about became her suitors. To rid herself of their importunities she bade them wait until she had woven a winding sheet for old Laërtes, the father of Odysseus. But every night she undid the piece that she had woven by day. This she did for three years, until her maids revealed the secret. She was relieved by the arrival of Odysseus. In the *Telegonia*, she married Telegonus, the son of Odysseus and Circe, after he had killed his father, and dwelt with him in the Island of Aeaea or in the Islands of the Blest. Probably quite distinct from her is an Arcadian Penelope, mother of Pan. *See* HOMER; ODYSSEUS.

PENGE, an urban district of Kent, Eng., which under the London Government Act 1963 was to be amalgamated with Beckenham, Bromley, Orpington and the southern part of Chislehurst and Sidcup to form the new London borough of Bromley (*see* LONDON). Penge urban district is residential with some industry (plastic goods, glass, buttons, general and aeronautical engineering). Pop. (1961) 25,743. Area 1.2 sq.mi. The Crystal palace, moved from Hyde park and opened at Penge place in 1854, burned down in 1936. In 1952 the London County council took over the site and plans were accepted (1955) for a national youth and sports centre and an exhibition centre to be built there, leaving the television mast of the British Broadcasting corporation standing. In Penge are the Watermen's almshouses (1840) and Queen Adelaide's Naval cottages (1847) for 12 widows of naval officers.

PENGUIN, a name for flightless, swimming seabirds widely known for their clownish behaviour and tuxedo-clad appearance. These birds of the Southern Hemisphere number 16 species, constituting the family Spheniscidae. The two southernmost species reach the Antarctic continent; others reach the coasts of New Zealand, Australia, South Africa, and southern South America; one, the most northerly species, lives on the Galápagos Islands on the Equator. Originally, "penguin" was applied to the now extinct great auk (*q.v.*), to which some spheniscids bear a likeness.

CAMERA PRESS—PIX FROM PUBLIX

ADÉLIE PENGUINS (PYGOSCELES ADELIAE): (LEFT) A GROUP ENTERING THE WATER; (RIGHT) PARENT BROODING CHICKS

Penguins range from duck size to a standing height of about four feet and a weight of 90 pounds (large emperor penguins). These birds are stout-bodied with short necks; stout bills; short, webbed feet placed far back on their bodies; short tails; and wings modified into flippers and covered with small scalelike feathers, without quills.

At sea penguins go in flocks. On the surface of the water the birds swim with little more than head and neck exposed. They travel and feed like porpoises, diving and surfacing repeatedly, with wings alone used for propulsion underwater, the feet serving only for steering. Penguins feed on fish and crustaceans.

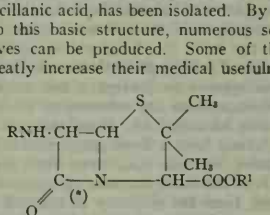
Penguins come ashore to nest in colonies, where there may be much calling and elaborate displaying. Usually the colony is near the edge of the sea, but occasionally it may be miles inland. The Adélie penguin (*Pygoscelis adeliae*) may travel as far as 60 miles over the ice to reach its nesting site in the Antarctic. These birds can leap seven feet out of the water to land on the ice. When traveling over the ice, they may walk upright or toboggan along on their bellies.

The emperor and king penguins (*Aptenodytes forsteri* and *A. patagonica*) lay a single white egg and incubate it by holding the egg on their feet and covering it with a loose fold of skin. Other penguins make nests of stones or of bits of vegetation in the open, under vegetation, in a rock crevice, or in a burrow that they dig. There they lay one to three white eggs and incubate them in normal fashion.

Both sexes take part in nest duties, but the share of each varies with the species. In the emperor penguin, nesting in the cold and dark of the Antarctic winter, the male alone incubates, without feeding, for the whole period of two months. In the Adélie penguin, nesting in the spring, the parents change places once in the 35-day incubation period, and in more northern species the changeover may be twice daily. The newly hatched young are scantily down covered but later develop a heavy down coat. Although they walk about, they must wait until they are full grown and feathered before going into the water. *See* also BIRD. (A. L. RD.)

PENIBÉTICO, SISTEMA (also called CORDILLERA PENIBÉTICA or BAETIC CORDILLERA), comprises the Andalusian Mountains of southern Spain. The northern mountains, or Sub-Baetic, run about 360 mi. from Cape Trafalgar to Cape Nao. The central and southern ranges, the Penibaetic proper, extend a shorter distance from Estepona to Cape Gata. Separating the two systems is a complex series of structures, traceable in longitudinal corridors and high basins for 180 mi. between Antequera and Baza, and again between Lorca and the Guadalentín Valley. The depressions are exhumed Tertiary basins, synclines, and grabens. To the south, in the Penibaetic proper, the interior mountains include the Sierra Nevada (*q.v.*), with the highest peak of the peninsula Mulhacén 11,411 ft. (3,478 m.), the Sierra de Baza (7,444 ft.), the Sierra de los Filabres (7,113 ft.), and the Sierra de las Estancias (4,783 ft.), oval domes orientated from east-northeast to west-southwest and separated by synclinal depressions, sometimes linked with Las Alpujarras (*see* ALPUJARRAS, LAS). Triassic limestones overlying ancient crystalline rocks comprise the highest summits. The lower, less continuous coastal ranges include the Sierra de Gádor (7,356 ft.), the Sierra de Almijara (6,017 ft.), and the Sierra Alhamilla (4,744 ft.). Vegetation ranges widely, from subtropical at sea level to alpine higher up, within distances of only 20 to 30 mi. (J. M. Ho.)

PENICILLIN is a powerful antibacterial substance elaborated by certain molds of the genus *Penicillium*. It is classified as an antibiotic; *i.e.*, a substance produced by living organisms that has a specific antagonistic effect on microorganisms. It was at first thought that there is only one penicillin, but it was later discovered that the mold can produce at least four penicillins called F, G, X, and K, which differed slightly in their chemical structure. Of these, only penicillin G has been used extensively. The penicillin molecule can be altered by adding substances to the fermentation liquor in which the mold is grown. The relatively stable compound that constitutes the basic ring structure of all penicillins, 6-Amino-penicillanic acid, has been isolated. By adding various side chains to this basic structure, numerous semisynthetic penicillin derivatives can be produced. Some of these possess properties that greatly increase their medical usefulness.



Basic Chemical Structure of Penicillin

In potassium penicillin G, R =  and R^1 = K. In 6-aminopenicillanic acid, R = H and R^1 = H. The asterisk on the C-N bond in the lower left part of the basic structure indicates the site of action of staphylococcal penicillinase.

History.—Penicillin was described and named by Sir Alexander Fleming (*q.v.*) in 1929. The work was initiated in 1928 by the unexpected contamination of a culture plate of staphylococcus by spores of *Penicillium notatum*. In the neighbourhood of the growth of the contaminating mold the colonies of staphylococcus, which had been well developed, appeared to be undergoing dissolution. The mold was isolated in pure culture and was found to produce a substance that had a powerful destructive effect on many of the common bacteria that infect man, while it had no effect on many others. This antibacterial substance, which was christened penicillin, was liberated into the fluid in which the mold was grown. This liberation is the basis of all commercial production of penicillin.

Although penicillin displayed a strong antibacterial action, it apparently was nontoxic to human cells. This combination of destructive action on bacteria and absence of toxicity for human cells was unique. All the antiseptics then in common use were more toxic to human cells than they were to bacteria. Subsequently it was discovered that penicillin acts mainly if not solely by inhibiting the synthesis of cell walls in bacteria. Animal cells do not have cell walls and this selective action is a reasonable explanation for the virtual lack of toxicity to human cells.

In 1939 a team of Oxford workers headed by Sir Howard Florey (*q.v.*) decided to investigate antibiotics. They selected penicillin as a promising one to commence with and succeeded in concentrating and purifying it. They demonstrated its curative properties first on experimental infections in mice and then on human patients suffering from staphylococcal and other infections. The next goal was production on a large scale. The Oxford workers developed methods of production and extraction, and in 1941 Florey took these to the U.S. and induced the authorities there to commence production. The pharmaceutical manufacturers in England also interested themselves and there was free interchange of information. The progress was phenomenally rapid and many advances in methods of production were made: (1) the culture medium was improved by the addition of "corn steep liquor" and other substances; (2) the fermentation was carried out in large tanks instead of in thousands of bottles; (3) it was found that

other strains of mold of the *Penicillium notatum-chrysogenum* group gave larger yields of penicillin than did the original strain isolated in 1928; (4) better methods of extraction were evolved.

The penicillin molecule has been synthesized (1957), but the synthetic method of production was found to be much less economical than production by mold fermentation. The materials used in the fermentation are cheap, so that when the initial outlay in manufacturing plant has been written off the cost of production of penicillin is relatively small.

Following World War II, penicillin G came into widespread clinical use. With the inexpensive production of a relatively pure compound, it became possible to administer increasingly larger doses for prolonged periods of time. Thus, bacteria that were relatively resistant to penicillin could be treated.

Theory of Penicillin Action.—Following the addition of penicillin to a culture of sensitive bacteria, the synthesis of mucopeptide, a component of the cell wall, stops. Compounds that appear to be the basis for the chemical building blocks of the highly polymerized mucopeptide then accumulate inside the cell. Penicillin thus appears to prevent a late stage of mucopeptide synthesis. Mucopeptides are common to all bacteria; however, in gram-positive bacteria (*i.e.*, those that can be stained with Gram's stain), they form a larger proportion of the cell wall than in gram-negative bacteria (*i.e.*, those that are not stained by Gram's stain); in the latter bacteria, special substances typical of a given species form the majority of the cell wall. As a rule, penicillin is more effective, molecule for molecule, on gram-positive than on gram-negative bacteria.

The action of penicillin in inhibiting cell-wall synthesis explains why the antibiotic is effective on actively growing bacteria. Although at minimally effective concentrations penicillin appears to be merely bacteriostatic (*i.e.*, capable of arresting bacterial multiplication), at slightly higher concentrations it is bactericidal (capable of killing bacteria). The morphological changes following exposure to penicillin have been studied thoroughly in some organisms, particularly the gram-negative bacilli. In one of these organisms, *Escherichia coli* (the commonest normal organism of the intestinal tract), the changes are as follows: At bactericidal concentrations, the rod-shaped organism develops a break in its cell wall. The intracellular components are then extruded through the opening and a curious form called a spheroplast is produced. The spheroplast has lost the rigidity provided by the cell wall and is vulnerable to changes in the salt concentration of the surrounding medium in that it can be lysed in distilled water but is protected by higher salt concentrations. Under suitable conditions the spheroplasts continue to grow and can divide to produce colonies that are markedly different from ordinary bacterial colonies. If penicillin is removed from the medium, they can usually revert to normal bacteria.

At concentrations approaching the minimally effective concentration the *Escherichia coli* do not form spheroplasts. Instead, the rods continue to grow longer as if the site of production of the intercellular septum is the most vulnerable area to the action of penicillin. If penicillin is removed from the medium, intercellular septa begin to grow and convert the elongated filamentous forms into a chain of rods.

Unit of Penicillin.—When the Oxford workers concentrated penicillin in 1940 they established a unit of potency. This corresponded with the amount that, when dissolved in 50 ml. of nutrient broth, would just inhibit the growth of their test organism, a staphylococcus. After penicillin was obtained in a pure and crystalline form an international unit corresponding to the original Oxford unit was agreed upon. This international unit is equal to 0.0006 mg. of penicillin G; consequently, 1,000,000 units represents 0.6 g.

Bacterial Resistance.—Resistance of bacteria to penicillin may be divided into two general categories: (1) that associated with the inherent resistance of the individual organism to penicillin; (2) that associated with the production of enzymes called penicillinases, which are capable of destroying penicillin. The first type of resistance may be virtually absolute, as with *Pseudomonas aeruginosa*, or it may be relative, as with many other gram-negative bacteria, such as *Escherichia coli* or *Proteus mirabilis*. Whereas the gram-positive bacteria, such as pneumococci, and hemolytic streptococci are sensitive to penicillin in doses of tenths to hundredths of a unit per millilitre, the relatively resistant gram-negative organisms may require from 1 to 100 units. Bacterial mutations that increase resistance to penicillin may be demonstrated in the laboratory, but, at least with gram-positive organisms, they are not encountered in the patient.

The second type of resistance, the ability to form penicillinases, is particularly important with respect to staphylococci. Some strains do not produce penicillinase and are susceptible to penicillin. Other strains produce the enzyme and, if they are present in sufficient numbers, may be resistant to large amounts of penicillin. After the use of penicillin became widespread, the penicillinase-producing strains became more common, particularly in hospitals and other places in which penicillin was widely used.

Therapeutics.—Penicillin is used for the treatment of many types of bacterial infections. For serious infections it is usually given intramuscularly or intravenously. It is rapidly excreted by the kidneys. Since the drug is virtually nontoxic, millions of units may be given and the dose may consequently be adjusted according to the species of bacteria, the location of the disease process, and the severity of infection. After injection the penicillin circulates in the blood and can affect organisms almost anywhere in the body except in the normal cerebrospinal fluid. However, in the presence of meningitis, penetration into the cerebrospinal fluid is improved and therapy with large doses of intravenous penicillin may be employed. The use of penicillin locally in the form of ointments, creams, powders, or sprays is discouraged since such methods of application result in uncertain levels in the tissues and are accompanied by an increased risk of allergic reactions in the patient.

One of the great social benefits of penicillin has been its effectiveness in the treatment of syphilis and gonorrhea. Although more prolonged treatment may be necessary for moderately resistant strains, a single dose is usually sufficient for the treatment of gonorrhea; syphilis requires more prolonged treatment.

Development of Additional Penicillins.—Although penicillin G is an extremely effective antibiotic it has certain deficiencies, which has encouraged the synthesis of variously modified compounds. Some, such as procaine penicillin, are absorbed more slowly after intramuscular injection, with the result that fewer doses need be given. Others, such as penicillin V, are acid stable and therefore give higher and more dependable levels after administration by mouth. Some penicillin compounds are relatively unaffected by staphylococcal penicillinase and can be used to treat infections caused by so-called "penicillin-resistant" staphylococci. Other penicillin derivatives are more effective than penicillin G against some gram-negative bacilli.

A species of mold isolated in Sardinia was found to produce at least three different antibiotics. This organism, a cephalosporium, produced two substances with properties similar to penicillin. One of these, cephalosporin N, has a ring structure identical to that of penicillin G, while the other, cephalosporin C, has a slightly different ring structure. Derivatives of this latter compound have different degradation products and do not appear to cause allergic reactions in individuals with a history of allergy to penicillin.

See ALLERGY AND ANAPHYLAXIS; ANTIBIOTICS; *see* also references under "Penicillin" in the Index.

PENINSULAR WAR, the name given to that part of the Napoleonic Wars (*q.v.*) fought between 1808 and 1814 in the Iberian Peninsula, where the French were opposed by British, Spanish, and Portuguese forces. Napoleon's Peninsular struggle contributed considerably to his eventual downfall, but until 1813 the conflict in Spain and Portugal, although costly, exercised only

an indirect effect upon the progress of French affairs in central and eastern Europe. The war in the Peninsula was of primary interest to the British, however, because their army made no other important or notably successful contribution to the war on the continent between 1793 and 1814. Not the least of Napoleon's mistakes in attempting the conquest of Spain and Portugal was that he thereby allowed the British to employ their limited army to greatest advantage.

Napoleon's pact with Russia at Tilsit (July 7, 1807) left him free to turn his attention toward Britain and Sweden and Portugal, the two powers which remained allied or friendly to Britain. Russia, it was decided, would deal with Sweden, while Napoleon, allied to Spain since 1796, summoned (July 19) the Portuguese "to close their ports to the British and declare war on Britain." His intention was to complete the continental system, designed to make economic war against Britain, for there was no other means to bring it to seek peace than by striking at its trade. Although this purpose was the immediate cause of his invasion of Portugal, his Spanish allies were to discover that he was also intent upon conquest for its own sake.

French Invasion of Portugal.—As the Portuguese refused to carry the conciliation of France to the point of confiscating British goods, a French expeditionary force of 30,000 men under Gen. Andoche Junot crossed the Bidassoa River on Oct. 18, 1807, to march through Spain, which was still the ally of France under the decadent government of Charles IV and his favourite, Manuel de Godoy. The abortive Franco-Spanish Convention of Fontainebleau of Oct. 27, 1807, determined the partition of Portugal: a northwestern province was to go to Charles Louis, king of Etruria, in return for the cession of Etruria to France; Algarve and Alentejo to Godoy; and the central territories and Lisbon to Napoleon. On Nov. 30 Junot arrived in Lisbon, from which on the previous day the Portuguese royal family and fleet had left for Brazil. Additional French forces began to enter Spain late in November 1807, ostensibly as reserves for Junot. Joachim Murat took over their command at Burgos on March 13, 1808. On March 23 he reached Madrid, where his approach had led to Godoy's arrest by the supporters of Charles IV's son Ferdinand (later Ferdinand VII) and the abdication (March 19) of Charles IV on behalf of Ferdinand. At Bayonne on May 10 Napoleon finally obtained both Spanish rulers' surrender of the throne, which he granted to his brother Joseph Bonaparte.

A brief rising against Murat in Madrid on May 2 was ruthlessly suppressed but was followed three weeks later by another at Oviedo, the first of many provincial insurrections throughout Spain. The revolt spread to such effect that Joseph, who reached the capital on July 20, abandoned it on Aug. 1, and subsequently withdrew to the Ebro River. Representatives of the insurrectionary junta from the province of Asturias had arrived in London on June 7, and were promptly offered support. The British government was soon to deplore the rivalries and particularism of the juntas (committees of administration) which were established in Andalusia, Galicia, Murcia, Valencia, Aragon, and Catalonia. Nevertheless, the strength of local sentiment played a substantial part in the formation of Spanish opposition to French rule as well as hindering the coordination of national resistance to Napoleon's forces.

Napoleon's army in the Peninsula, including Junot's corps, numbered only 116,000 by May 31. Of these, less than one-third came from the regular French Army, the rest being composed of recently incorporated conscripts and foreign auxiliaries. The front-line troops of the *Grande Armée* remained in Germany. The regular Spanish forces were too few, too dispersed, and too ineffective to endanger the French, who were principally concentrated around Madrid and in the north. At first mistaking the revolt to be no more than isolated risings, Napoleon detached 22,000 men from the 53,000 around Madrid to pacify Andalusia and Valencia. This dispersal led to a serious reverse, for at Bailén on July 23 the outnumbered Gen. Pierre Dupont surrendered to the rebels with a loss in casualties, captured, and deserters of 17,600 men. This defeat had a considerable effect on European opinion, the more so because Dupont's poor handling of operations, the inadequacy of his troops, and the presence of a large majority of regular soldiers in the opposing Spanish forces were generally overlooked.

The Campaign in Portugal, 1808.—Sir Arthur Wellesley (later duke of Wellington) disembarked in Mondego Bay in Portugal with an expeditionary force of 13,500 men on Aug. 1 and his army was swelled by 5,000 national troops. Three weeks later at Vimeiro, near Lisbon, where Wellesley had about 19,000 men, he was attacked by Junot's force of 13,000. The French were severely defeated (Aug. 21), but the new British commander in chief, Sir Hew Dalrymple, who arrived immediately after the battle, proved unwilling to exploit Wellesley's success. On Aug. 31 Dalrymple concluded the Convention of Sintra with the French. Its terms were of arguable advantage to the British, for they provided for the evacuation to France of the French Army in Portugal, more than 25,000 men, who were thus able to return to Spain in December 1808; on the other hand, the British occupied Lisbon on Sept. 9 and were free to march eastward into Spain to assist the insurrectionaries.

Sir John Moore's Campaign of 1808–09.—Meanwhile the French had been driven back by the Spaniards behind the line of the Ebro, where they were confronted by four ill-equipped and badly coordinated Spanish forces. In September the British government decided that its troops in Portugal should support the Spanish on the Ebro, and by mid-October Sir John Moore, the new commander in chief, with an army of 20,000 strong, had begun his march northeastward toward Salamanca. By way of reinforcement, 12,500 men under Sir David Baird were ordered to leave England for Corunna and to join Moore, if possible at Valladolid. Napoleon, however, determined to increase his numbers in Spain and to resume the offensive. By late October he had assembled nearly 120,000 front-line troops on the Ebro, where he assumed personal command of 70,000 at Vitoria on Nov. 6. One Spanish army had been defeated at Zornosa, near Durango, on Oct. 29, another at Espinosa de los Monteros on Nov. 11, and on Nov. 23 at Tudela, on the Ebro, the Spanish were finally routed. On Dec. 4 Napoleon occupied Madrid, where he issued a stream of decrees for the reorganization of Spanish affairs, including the closure of two-thirds of the religious houses.

Moore halted his march at Salamanca on Nov. 14 when he received news of the Spanish defeat at Zornosa and of the French advance toward Valladolid. In the north, Baird had arrived at Corunna with his infantry on Oct. 13, and after a month's delay for his cavalry to join him, he set out for Astorga, which he reached on Nov. 22. There he heard at last of the Spanish reverses at Zornosa and at Espinosa de los Monteros and decided to suspend his march. Moore had remained at Salamanca where he learned on Nov. 28 that the forces on the Spanish right had been defeated at Tudela on the 23rd. He resolved at once to withdraw to Portugal, called in his detachments and sent Baird instructions to retire on Corunna, where he was to embark his men to join Moore in Lisbon. Soon afterward, however, Moore was asked by J. H. Frere, the British minister at Madrid, to make an effort to save the capital, and although very doubtful of the wisdom of such a policy, on Dec. 5 he ordered Baird to return to Astorga. Hearing on Dec. 9 that Madrid had fallen, Moore determined to take advantage of the dispersal of the heavily superior French forces and strike at their communications by attacking N. J. de Dieu Soult's isolated corps of 20,000 men west of Burgos. When Baird joined him at Mayorga on Dec. 20 his effective strength rose to 26,000 men.

Two days later Napoleon realized that far from withdrawing into Portugal Moore had set out on this hazardous enterprise and he hastily deployed more than 80,000 men in an enveloping movement against him. It was not until Dec. 23, when he had completed his preparations to attack Soult next morning, that Moore heard the not unexpected news of Napoleon's advance, and ordered an immediate withdrawal on Corunna. The British retreat over the mountains of Galicia was hurried and painful, but Moore succeeded in keeping ahead of his pursuers. Napoleon gave up personal direction of operations on Jan. 3, 1809, and soon afterward left for Paris to meet the danger from Austria, whose preparations for war had been encouraged by the large number of

French troops confined in the Peninsula. Moore reached Corunna on Jan. 11, three days before his transports arrived. He took up a position with 15,000 men and 9 light cannon in order to cover his embarkation, and was attacked on Jan. 16 by Soult, who had about 16,000 men and 40 guns. The French were repulsed, but Moore lost his life in the battle which enabled his army to take ship for England. In itself, his campaign had been unsuccessful, but it secured substantial benefits by drawing Napoleon's troops from southern Spain and from Portugal.

WELLINGTON'S CAMPAIGNS, 1809–14

Although Napoleon's brief campaign of 1808 had disclosed some of the obstacles to the conquest of the Peninsula, his personal commitment to the enterprise and his over-optimistic appreciation of its long-term requirements led him to persist in his largely unnecessary undertaking. One important consequence of the British government's decision to continue its support of the insurgents after the return of Moore's force to England was the choice (March 1809) of Sir Arthur Wellesley (created Viscount Wellington in September 1809) as the commander of the British forces in Portugal. Wellington was quick to perceive the opportunities offered him by the peculiarities of the strategic situation, and after his first campaign he exploited them with mounting success. His task was anything but easy. At the outset, his army, with reinforcements, numbered only 26,000. The operations in Portugal were poorly supported and widely criticized at home until Wellington obliged André Masséna to retire from the lines of Tôrres Vedras in March 1811 (*see* below). Caution had been enforced upon him in these first difficult years; the brilliant and victorious campaigns of 1812–14 when he had a stronger hand were to demonstrate, if proof were still needed, the extent of his military and political gifts, and the judgment and tenacity of purpose with which he had earlier followed his course. He supplemented his small numbers to some extent by the Portuguese, whose troops were reorganized under William Carr (later Viscount) Beresford and other British officers and of which there were more than 50,000 in the field by 1810; the Portuguese Militia too was used for support purposes.

The Spanish, however, took less kindly to British direction; their governments, unstable and short-lived, and their regular army, ill-equipped and inefficiently led, failed to cooperate effectively with Wellington. Thus the British, who alone of the allies possessed properly constituted forces, provided almost all the effective conventional resistance to Napoleon's army. Yet it was the bitter opposition of the Spanish people which furnished the conditions necessary for so much of Wellington's success, and which, all in all, decided the outcome of the Peninsular War. Reluctant to organize, support, or join a substantial regular army, large numbers elected to engage in local guerrilla warfare fought with exceptional savagery on both sides.

The guerrillas' activities, whether inspired, as in many cases, by genuine patriotism and religious fervour, or as in some instances, verging upon brigandage, took a daily toll of men and supplies and obliged the French to make constant detachments to control disaffected areas and protect rear services. Not only were the French further handicapped by inadequate roads and difficult terrain, but the country could not support their numerically superior armies, even where it had not been ravaged by earlier operations. Thus their campaigning forces were often unable to remain united for long enough to defeat the usually inferior regular formations opposed to them.

These conditions Wellington turned to great effect in his early years when he lacked the men and matériel to undertake a prolonged offensive. His strategy also drew strength from the more positive advantages that his lines of retreat were guaranteed by command of the sea, and that he was provisioned in part by sea transport. Moreover, to increase his freedom of movement he organized an effective system of supply in the field. By these means, and his outstanding success in raising the technical efficiency of his army, the series of limited operations in the early campaigns enabled Wellington to secure his hold on Portugal and to inflict substantial losses on the dispersed French armies.

Campaign in Portugal and Spain, 1809.—Wellesley reached Lisbon from England at the end of April 1809 to find that the French had made considerable progress toward the conquest of the Peninsula. After the Battle of Corunna (January 1809) Soult had marched south into Portugal, where he had taken Oporto (March); he was now opposed only by some disheartened Portuguese levies. Michel Ney, who had also joined in the pursuit of Moore, was engaged farther north in the pacification of Galicia. The French force closest to Wellesley was that under Claude Victor Perrin at Mérida, within 40 mi. of the Portuguese frontier, well placed to invade Portugal via the Tagus River and opposed by no more than the demoralized army of the Spanish general, Gregorio de la Cuesta, who had been defeated on March 28 at Medellín, east of Mérida. The central Spanish army had suffered two earlier defeats, at Ucles, east of Ocaña, on Jan. 13, and at Ciudad Real on March 27. To the east, in Catalonia, the French general, Gouvion-Saint-Cyr, had gained substantial victories over the rebels.

Soult and Victor, however, had both halted their advance by April and were separated by 200 mi.; furthermore, although they were meant to be acting in concert, they were not in communication. Wellesley, whose total forces numbered 25,000 British and 15,000 Portuguese under Beresford, advanced northward from Coimbra against Soult on May 7. Suspecting nothing, Soult had scattered his encampments north and south of Oporto. Wellesley failed to cut off the detachments south of the town, but surprised the French by crossing the Douro River on the 12th just above Oporto. The French began their retreat northward in the utmost confusion, and their destruction was averted only by the timidity of Gen. George Murray, one of Wellesley's divisional commanders. Soult had lost nearly 6,000 men and all his artillery when his hard-pressed withdrawal ended at Lugo on May 23. His escape owed much to the fact that reports of Victor's advance on the Tagus made Wellesley abandon the pursuit on the 18th.

Victor's movement was in fact a reconnaissance in force to obtain intelligence of Soult, but when Joseph Bonaparte in Madrid received news from Paris of Soult's reverses he ordered Victor to withdraw along the Tagus to Talavera de la Reina. At Lugo, Soult quarreled violently with Ney and the joint operations they had planned to mount against the Galician insurgents came to nothing; Galicia, in fact, remained in rebel hands for the rest of the war. By the beginning of July Joseph was in a position, if necessary, to concentrate 100,000 in the Tagus valley; Ney and Soult had moved southward to Astorga and Benavente and their force, together with Edouard Mortier's corps at Valladolid numbered 50,000; Joseph disposed of 27,000 men in the region of Madrid; at Talavera Victor's corps numbered 23,000.

On his return (June) to Abrantes from northern Portugal Wellesley proposed that he with 23,000 British troops, and Cuesta, who brought 36,000 Spanish on campaign, should advance on Madrid by way of the Tagus. The British marched on June 27 to join Cuesta at Plasencia and on July 17 the allied armies set out for the capital. Wellesley was soon made aware of his error in undertaking operations conjointly with the Spanish; not only was the elderly and incompetent Cuesta unwilling to cooperate, but his unreliable troops had been sent into the field without the supplies and transport promised by the Spanish government. Victor fell back before the allies until reinforcements from Joseph brought his strength up to 46,000 men. When, accordingly, the allies were obliged to retire from their position just east of Talavera, the disorder of the Spanish troops turned retreat into flight. With much difficulty Wellesley halted the panic and on July 27 took up his position at Talavera, where, that night and next day, he drove off Victor's attacks, suffering 5,000 casualties as against Victor's loss of 7,000 men and 17 guns. On Aug. 1 Soult's arrival in the Tagus valley from the north put an end to any thought of exploiting Victor's repulse, and Wellesley hastened to withdraw his army into Portugal via Badajoz. For his success at Talavera, Wellesley was created Viscount Wellington in September 1809.

The Spanish embarked on a new campaign during the winter of 1809, and at Ocaña on Nov. 19 Carlos Areizaga, Cuesta's successor,

was totally defeated. Against this reverse, however, could be set the wasteful diversion of the troops under Soult and Joseph, who invaded Andalusia in January 1810. There the French undertook the futile enterprise of besieging Cadiz, which was virtually impregnable without the assistance of a naval force and whose garrison was presently reinforced by 8,000 British troops.

Of more importance was the fact that Napoleon had defeated Austria at the Battle of Wagram (July 1809) and the end of the war with Austria (October 1809) had released 138,000 men for service in Spain. Greater numbers, however, were required to achieve superiority over the regular armies in the field while containing guerrilla activity. Napoleon added to the difficulties by attempting to direct operations from Paris, and the differences between the French marshals, whom Joseph proved unable to subordinate to a common purpose, greatly hindered coordinated offensives against the British. Within a year of Wagram, moreover, Napoleon's preoccupation with the situation in eastern Europe prevented him both from imposing a unified strategy in Spain and from concentrating sufficient forces to overcome allied resistance.

Wellington's Plans for the Defense of Portugal.—There were three principal routes by which the French could attack Wellington in Portugal: from the northeast, via Salamanca and Almeida (a frontier town in Portugal, northwest of Ciudad Rodrigo); from the east, along the line of the Tagus River; and finally, from the south, by way of the Guadiana River. Wellington had to reckon with the first two of these approaches: the third was blocked by the fortress of Badajoz which remained in Spanish hands. In consequence he would have to divide his forces to cover both avenues, but he could expect that in all probability the French would not attack him in strength along both routes at the same time. Although they could bring heavily superior numbers against him, he could hope that the problems they would encounter in supplying their army, together with the mobility he would gain from the reorganization of his own commissariat, would redress the balance in his favour. The keystone to his carefully considered plans to meet the French was furnished by the construction between the Tagus and the sea of the elaborately fortified lines of Tôrres Vedras, 25 mi. N of Lisbon. These sealed off the peninsula containing his base from virtually any attack the logistic difficulties of the position would permit the French to mount.

Campaign of 1810.—For the campaign of 1810, 65,000 French were assigned to the army of Portugal under André Masséna, while Soult commanded as many in the army of Andalusia. With 18,000 British and 14,000 Portuguese, Wellington awaited Masséna near Almeida. The route by the Tagus was guarded by Gen. Sir Rowland Hill with about 20,000 men, mostly Portuguese. After the siege and capture (July 10) of the fortress of Ciudad Rodrigo, Masséna's troops entered Portugal. Wellington fell back before their advance to Bussaco, north of Coimbra, where, having summoned Hill to him, he took up a very strong position with 52,000 men and offered battle. Masséna attacked on Sept. 27 with about 60,000 and was repulsed with 4,600 casualties as against Wellington's 1,250. The allied retreat was now resumed and on Oct. 10 Wellington's army occupied the lines of Tôrres Vedras. Masséna remained before them for a month before want of subsistence obliged him to retire 30 mi. NE to Santarém to continue his observation of the allies.

The reason for Masséna's persistence—the expectation that the Whigs would replace the existing ministry in Britain and so implement their demands for the withdrawal of British forces from the Peninsula—was not the only consideration which gave Wellington cause for alarm at the beginning of 1811. In January 1811 Soult advanced from Andalusia on Badajoz. The Spanish Army there offered battle (known as the Battle of Gebora) on Feb. 19 in spite of Wellington's plea that it should not, and, as he expected, it was defeated. On March 5, Masséna at last began his retreat from Santarém toward Salamanca, followed by Wellington with 44,000 men. Of these, he was obliged to send 7,000 at once to Beresford, who had already been ordered to march against Soult, because Badajoz had been quite unjustifiably surrendered to Soult on March 10. Pursued by Wellington's remaining forces, early in April Masséna's exhausted troops crossed the Portuguese frontier en route for Salamanca. His fruitless campaign had cost him 25,000 casualties.

Campaign of 1811.—Meanwhile the allied forces invested at Cadiz had gained a successful action against their besiegers at the Battle of Barrosa (March 5). In consequence, Soult hurried back from Badajoz to Andalusia. On April 22, Beresford, whose Anglo-Portuguese force had been raised to 18,000 men, laid siege to Badajoz. The main allied army, which had suspended its pursuit of Masséna, was now engaged in the blockade of Almeida. Masséna returned to its relief, and the two armies met at Fuentes de Oñoro on May 3, when Masséna was driven off with a loss of 650 men to Wellington's 250, and again on the 5th, when Masséna attempted a general assault against Wellington's faulty position and was repulsed chiefly by the steadiness of the allied troops. His forces on that day suffered 2,200 casualties to Wellington's 1,450. Two days later Masséna began his retreat to Salamanca. The French abandoned Almeida on the 10th.

Soult returned from the south with 24,000 men in May to attempt the relief of Badajoz. Beresford gave battle, inexpertly, with 24,000 Spanish and Portuguese and 10,000 British troops at Albuera, southeast of Badajoz, on May 16. The resolution of Beresford's troops saved the day, and obliged Soult to retire with a loss of 8,000 casualties. The British casualties, however, numbered 4,000 and their allies' 1,760. A fortnight later Wellington resumed the siege of Badajoz with inadequate Portuguese cannon. The siege was again raised on June 10, when Wellington withdrew his 37,000 British and 17,000 Portuguese troops behind the Caia River, west of Badajoz, to oppose Soult and Auguste Marmont, who had replaced Masséna. The two marshals joined forces at Mérida on June 17 and advanced toward Wellington with nearly 60,000 before they decided to avoid battle. Disagreement between them led next to Soult's departure (June 28) for Andalusia, and Marmont, with 43,000 men, withdrew north on July 15 to the Tagus valley. While the bulk of his forces remained to protect the eastern frontier, Wellington brought his siege train from Lisbon to blockade Ciudad Rodrigo (Aug. 11). Marmont advanced with 58,000 men to its relief, but when Wellington raised the blockade to await him with 30,000 British and 16,000 Portuguese troops, Marmont contented himself with a reconnaissance in force on Sept. 25 and retired to the Tagus on Oct. 1.

Campaign of 1812.—Anxious to secure the northeastern approach to Portugal, Wellington again invested Ciudad Rodrigo on Jan. 8 and captured it by storm, with a loss of 550 casualties, on Jan. 19, long before Marmont could intervene. After remaining in cantonments Wellington's troops marched on Feb. 16 and besieged Badajoz on March 16. The fortress fell on April 6, and cost Wellington 5,000 casualties. The French had already lost their siege train at Ciudad Rodrigo and now at Badajoz their pontoon train was captured. On May 19 a detachment under Hill captured and destroyed the French bridge of boats across the Tagus at Almaraz and so forced Soult and Marmont to use the bridge of Toledo for their communications.

While Hill remained with 22,000 men at Mérida to keep watch on Soult, Wellington on June 13 advanced with 48,000 British and Portuguese against Marmont at Salamanca. Marmont withdrew north to the Douro River until the arrival of reinforcements enabled him to assume the offensive on July 16 in a manœuver against Wellington's communications. A race ensued between the two armies to obtain a favourable position for battle; on more than one day they marched in parallel columns separated by only a few hundred yards. Finally, on July 22, at the Battle of Salamanca Wellington seized the opportunity afforded by the isolation of Marmont's left wing from the rest of the French Army to inflict a crushing defeat on his adversary. The allies, with Spanish reinforcements, disposed of 50,000 men and 60 guns; Marmont had 48,000 and 78 guns. Wellington suffered 4,760 casualties, Marmont's losses numbered 14,000 men and 20 guns.

The French withdrew to Burgos, which Wellington proceeded to besiege (Sept. 19) after his triumphant entry into Madrid on Aug. 12. The concentration against him of French troops from all over Spain obliged him to abandon his unsatisfactory invest-

ment of Burgos on Oct. 22 and begin his retreat. With difficulty he gained time for Hill to join him as he withdrew. At Salamanca on Nov. 11 the French with 90,000 refused his offer of battle with 68,000 troops, and eight days later his retreat and the campaign ended at Ciudad Rodrigo. His extremely skilful retreat had cost him 6,000 casualties. The advance on Madrid was undoubtedly a mistake, but the campaign had been brilliant. The French had suffered far higher casualties, including 20,000 captured, and had been driven out of all Spain south of the Tagus.

Campaign of 1813.—While the catastrophic outcome of Napoleon's campaign in Russia in 1812 obliged him to draw heavily on his forces in the Peninsula, Wellington marched from Portugal to begin the campaign of 1813 with an army of 100,000 men, of whom 52,000 were British. In Biscay and Navarre the activities of the Spanish guerrillas occupied the attentions of four French divisions under Gen. Bertrand Clausel. The French were unable to defend the Douro, and fell back northeastward, abandoning Burgos, to the line of the Ebro. When Wellington turned the northern flank of this position, Joseph, advised by Marshal Jean Baptiste Jourdan, decided to fight a delaying action south of Vitoria to cover his further retreat. Joseph had only 57,000 men, for Clausel, despite repeated orders, had not joined him; he was attacked on June 21 by Wellington with 72,000. Had Wellington's orders been followed, few of the French would have escaped. Yet although Joseph's casualties were only 8,000 to Wellington's 5,000, he lost the whole of his artillery train, 150 guns, and all his baggage. The French retreated over the Pyrenees into France. Wellington halted his pursuit at Pamplona, for it was necessary first to reduce the fortresses of Pamplona and San Sebastian before the allies could continue their advance. Until these should fall he occupied the main western passes of the Pyrenees on a front about 50 mi. SE of San Sebastian.

On July 12 Soult arrived to take over from Joseph command of the troops who had retreated from Spain. Just over a week later he launched a counteroffensive with 70,000 men along the three main valleys of the Pyrenees which lead to Pamplona. Against Wellington's divisional commanders Soult achieved some initial success, but when he encountered 16,000 under Wellington at Sorauren, northeast of Pamplona, on July 28, his attack with 30,000 was repulsed with heavy loss. Wellington now followed up his advantage and after six days' fighting had driven the thoroughly disorganized French back to the northern slopes of the Pyrenees. Between July 25 and Aug. 2 Soult lost 13,000, Wellington about half as many.

San Sebastian, first assaulted by the allies on July 25, was then blockaded, owing to lack of ammunition, until Aug. 22, when the siege was resumed; the fortress was successfully stormed with considerable loss of life on Aug. 31. In all it had cost over 3,700 casualties. Soult made a final effort to save San Sebastian on the day of its capture, and was driven off after two days' fighting with a loss of 3,800 casualties as opposed to the allies' 2,600. He next resolved to stand on the defensive and constructed a fortified line to the south of the Bidassoa River. This Wellington attacked in October and carried after the combats of Oct. 7–9 with losses of about 1,600 to both sides. Soult then proceeded to prepare a fresh position to the north on the Nievelle River, and Wellington, having brought his troops across the Bidassoa, halted his advance to await the fall of Pamplona. The fortress was captured on Oct. 25. On Nov. 10 the allied army drove Soult's troops from their lines on the Nivelle, capturing 59 guns; the French suffering approximately 4,300 casualties, the allies about 3,500. At this point Wellington was compelled to send most of his ill-found Spanish troops back to Spain, for he was anxious that they should not jeopardize his position by their maltreatment of the French population.

The Invasion of France, 1814.—With the news on Dec. 8, 1813, of Napoleon's decisive defeat at Leipzig (October) came orders that Wellington should press his invasion of France. Next day he attacked Soult in his position on the Nive River south of Bayonne. The engagement lasted for five days, Soult launching unsuccessful counterattacks on Dec. 10 and 11, and again on the 13th. Having lost 5,900 in the five days' fighting, which cost the allies 5,000, Soult withdrew to the Adour River. Bad weather delayed the operations against Soult's new front until mid-February 1814, when Wellington began a series of skilful movements in which he maneuvered Soult out of his position on the Adour (Feb. 19–24). Leaving Sir John Hope to besiege Bayonne, Wellington set out in pursuit of Soult. He overtook the French at Orthez on Feb. 27, and with 43,000 men drove Soult's 37,000 from the field; his victory cost him 2,000 casualties, Soult losing twice as many. The British continued to press Soult's retreat until bad weather brought them to a standstill and contact was lost on March 3.

While Soult hurried his disorganized troops in the direction of Toulouse and did not halt until Tarbes, where he arrived on March 18, Wellington occupied Bordeaux to provide a new sea base. On March 18 Wellington resumed the pursuit with an army raised to nearly 50,000 men by the arrival of a Spanish contingent and engaged Soult's rear guard during the 19th. Next day Soult fought a small and unprofitable combat at Tarbes which delayed his withdrawal and made him retire on Toulouse in the utmost confusion. Wellington, however, moved after him slowly, delayed by heavy rain and made cautious by reports that Napoleon had fallen back to Orléans, which might mean that the emperor intended to join forces with Soult and raise southern France against the allies.

When Wellington appeared before Toulouse on March 26 he was still unaware of Napoleon's defeat on the previous day at La Fère-Champenoise. The condition of Soult's army encouraged Wellington to dispense with most of the preparatory operations and the precautions that an attack on the very strong French position would have normally demanded. The allied army's hazardous assault on April 10 cost him 4,500 casualties, half again as many as Soult's, but on the 12th Soult evacuated Toulouse to continue his retreat. The same day Wellington received news of the fall of Napoleon and at once informed Soult. The last engagement was fought at Bayonne where the French garrison made a sortie on the night of the 14th, which cost them 900 and the allies 800 casualties. On the 18th an agreement for the suspension of hostilities was signed and the Peninsular War was over.

PENITENTIAL, a manual used by priests of the Western Church, especially during the early Middle Ages, in administering ecclesiastical penance. Penitentials contained (1) detailed lists of sins which the priest was to consider in assisting the penitent with his examination of conscience and confession; and (2) corresponding penances which were to be assigned by way of satisfaction for these sins. Penitentials originated as a development of the church's traditional belief that sin may not be pardoned by ecclesiastical authority except on condition that a penance properly proportioned to the offense be performed. In the early church the determination of the length and severity of this penance was left to the discretion of the local bishop or his delegate, the so-called priest-penitentiary. In some instances, however, church councils and eminent ecclesiastics enacted canons which stipulated the penance to be done for certain grave sins. The unrealistic severity of public penance led to its gradual decline and prepared the way for the introduction of private penance, a form of ecclesiastical pardon which retained all the essential juridical features of the older ritual—contrition, confession, satisfaction, and absolution granted by the bishop or priest—yet no longer required the

enrollment of the sinner among the penitents who were publicly expiating their guilt. (*See* also CONFESSION: *Discipline of Penance.*) Penitentials played a significant role in the development of private penance, since, as their use spread more and more widely among the parish clergy, the concept of ecclesiastical penance as involving public excommunication gradually receded, until its only vestige remained in the directive that no one guilty of serious sin should approach the Eucharist until after having first received absolution in the sacrament of penance.

For reasons closely connected with the rise of Celtic monasticism, the first penitential books appeared in Ireland and Wales. The earliest extant compilations are probably those associated with St. David and various Welsh synods of the 6th century, though the so-called *Canons of St. Patrick* (*c.* 450) are occasionally, and somewhat loosely, spoken of as the first penitential. Among the more important of the early books are those of St. Finnian (*c.* 550), St. Columban (*c.* 600), and the influential penitential attributed to Theodore, archbishop of Canterbury (668–690). The Celtic penitentials were brought to the continent of Europe by missionary monks at a very early date. Their introduction met with opposition of ecclesiastics who favoured the older, traditional public penance, but there is considerable documentary evidence that penitential books were in use among the Franks by the late 6th century, in Italy by the late 8th century, and among the Spanish Visigoths by the early 9th century.

Besides their importance in the history of theology, the penitentials are of value to the philologist as source material for comparative studies of Latin, Anglo-Saxon, Old Irish and Icelandic forms; to the social historian for the vivid, often revolting picture they present of the manners and morals of barbarous peoples just coming under the influence of Christianity; and to the student of jurisprudence for the information they afford relative to the early history of composition by payment of the *wergeld.*

PENN, SIR WILLIAM (1621–1670), British admiral who fought in the first two Dutch Wars (1652–54 and 1665–67) and who commanded the expedition which captured Jamaica in 1655, was born at Bristol on April 23, 1621. In his youth he served at sea with his father, a merchant and naval captain, and in the Civil War fought for Parliament, being appointed rear admiral of the Irish seas in 1647. He was arrested in 1648 on suspicion of corresponding with Charles I, but was soon released. In 1651 he pursued the royalist ships under Prince Rupert in the Mediterranean.

On the outbreak of the First Dutch War in 1652, Penn was appointed vice-admiral to Robert Blake and was present at the battle in the Kentish Knock on Oct. 8–9 (new style; Sept. 28–29, old style). He took part in the three days' battle off Portland on Feb. 28–March 2 (N.S.; Feb. 18–20, O.S.), 1653, and also served in the final battles of the war. He was made a general of the fleet in December 1653. After secretly offering in 1654 to carry the fleet over to Charles II, then in exile, he sailed in December in command of the expedition which Oliver Cromwell sent to the West Indies, and which captured Jamaica in May 1655. Although he was not responsible for the shameful repulse at Santo Domingo, Hispaniola, in April, on his return to England he and his military colleague Robert Venables were sent to the Tower of London (September 1655). Released in October, he retired to Ireland.

He continued to communicate with the royalists and at the Restoration in 1660 was knighted and appointed a commissioner for the Navy. In the Second Dutch War (1665–67) he served as captain of the fleet with the duke of York (afterward James II) at the battle off Lowestoft on June 13, (N.S., June 3, O.S.), 1665. Penn died at Wanstead, London, on Sept. 16, 1670, and was buried in the church of St. Mary Redcliffe, Bristol. By his wife Margaret he was the father of William Penn, the founder of Pennsylvania. Penn was the author of a code of naval tactics which was the basis of the "Duke of York's Sailing and Fighting Instructions," for long the orthodox tactical creed of the Navy.

PENN, WILLIAM (1644–1718), English Quaker, advocate of religious toleration, and founder of Pennsylvania, was born at Tower Hill, London, on Oct. 14, 1644, the son of Admiral Sir William Penn. He acquired the foundations of a classical education at Chigwell school, where he came under Puritan influences, and went on in 1660 to Oxford, from which he was "sent down" at the beginning of his second year for nonconformity. (He was later to denounce the English universities as "Signal Places for Idleness, Looseness, Prophaneness, Prodigality, and gross Ignorance.") After a period of travel on the continent of Europe, during which he spent nearly two years at the Protestant university of Saumur, France, he returned to England to give himself briefly to the study of law at Lincoln's Inn. This was the extent of his formal education; but, such as it was, it was to stand him in good stead in his writings and his encounters with British justice.

WILLIAM PENN. PORTRAIT IN PASTEL BY FRANCIS PLACE (1647–1728) IN THE HISTORICAL SOCIETY OF PENNSYLVANIA

Quaker Activities.—In 1666 his father sent him to Ireland to manage the family estates. It was there that he decided to throw in his lot with the despised sect of Quakers (*see* FRIENDS, SOCIETY OF). The instrument of his "convincement" was Thomas Loe, an itinerant Quaker preacher of Oxford. For his presence at a Quaker meeting at Cork in 1667 Penn was thrown into prison—the common fate of the Quakers under the Clarendon code. He was quickly released, but not before he had expressed in a letter to the earl of Orrery, lord president of the province of Munster, Ireland, his commitment to the principle of religious freedom. His father, outraged by his devotion to his new found faith, threatened to disinherit him, but young Penn refused to be turned aside and soon emerged as an able and outspoken defender of the religion of the Inner Light.

Truth Exalted (1668), a pamphlet attacking in turn the doctrines of the Roman Catholics, the Anglicans and the dissenting bodies, marked his entry into the theological lists. Before his literary career was over, Penn was to publish more than 100 works, ranging in length from broadsheets to lengthy books. *Truth Exalted* was followed by *The Sandy Foundation Shaken* (1668), in which he questioned the doctrine of the Trinity as commonly received. Though later, in *Innocency With Her Open Face* (1669), he qualified his heterodoxy, he was committed to the Tower of London. In the tower he wrote his most famous book, *No Cross, No Crown* (1669), in which he expounded with learning, eloquence and occasionally humour, the Quaker-Puritan morality. Perhaps the book's most characteristic dictum is: "True Godliness don't (*sic*) turn Men out of the World, but enables them to live better in it, and excites their Endeavours to mend it"—a sentence which reflects both the Puritan conception of "intramundane asceticism" and the Quaker ideal of social reform. *No Cross, No Crown* stands alongside some of the letters of St. Paul, Boëthius' *Consolations of Philosophy* and Bunyan's *Pilgrim's Progress* among the world's finest examples of prison literature.

Though many of Penn's doctrinal and devotional works have lasting value, it is as a protagonist by word and act of religious toleration that he earned his prominent place in English history. In 1670 he wrote *The Great Case of Liberty of Conscience*, the most systematic and thorough exposition of the theory of toleration produced in Restoration England. Though he founded his arguments on theological and Scriptural grounds, he did not overlook rational and pragmatic considerations: he pointed out, for instance, that the contemporary prosperity of Holland was based on "her Indulgence in matters of Faith and Worship."

In that same year he had an unsought opportunity to strike another blow for freedom of conscience and for the traditional rights of Englishmen. On Aug. 14, 1670, the Quaker meeting-house in Gracechurch street, London, having been padlocked by the authorities, he preached in the street to several hundred persons. After the meetings, he and William Mead were arrested and imprisoned for riot. A full account of their trial in the Old Bailey, a vivid courtroom drama, was soon published under the title *The People's Ancient and Just Liberties Asserted* (1670). With calm courage born of his Quaker faith and with skill in pleading derived from his legal training, Penn exposed the illegality of the proceedings; the jury, under the leadership of one Edward Bushell, manfully resisted the browbeating of the mayor and recorder. For their refusal to bring in a verdict of "Guilty," as directed by the bench, the jurymen were fined and imprisoned; but they were vindicated, when Sir John Vaughan, lord chief justice, enunciated the principle that a judge "may try to open the eyes of the jurors, but not to lead them by the nose." "Bushell's case" stands as a landmark in English jurisprudence, establishing beyond question the independence of the jury.

Sir William Penn died in 1670, having finally become reconciled to his son's Quakerism. Young Penn inherited his father's estates in England and Ireland, and became, like his father, a frequenter of the court, where he enjoyed the friendship of Charles II and his brother James, an unusual experience for a Quaker. In 1672 he married Gulielma Springett, daughter of Mary Penington by her first husband Sir William Springett, and stepdaughter of Isaac Penington, a Quaker, like Penn, of high birth and literary attainments. Of this marriage eight children were born, four of whom died in infancy.

During the 1670s Penn was ceaselessly busy as a polemicist and minister, producing no less than 40 controversial tracts, in which he engaged theologians of various persuasions on matters of religious doctrine and practice. These productions are probably the least interesting of his writings to the modern reader, though they were of the utmost importance to the Society of Friends, still struggling to vindicate its place among Christian bodies and fortunate to have so able and fluent a defender. Penn also undertook two preaching missions to the continent. In 1671 he traveled through Holland and into northern Germany visiting small groups of Friends and religious seekers, including the followers of the mystic Jean de Labadie (who rebuffed him) and the princess palatine Elizabeth (who welcomed him gladly). Six years later, in company with George Fox, Robert Barclay and George Keith, three of the foremost Quakers of the time, he made another missionary journey through the same region, renewing his friendship with Princess Elizabeth and established contacts which would later help him in peopling Pennsylvania with emigrants from the Low Countries.

The latter years of the decade were occupied with political activities. In the midst of the excitement generated by the "popish plot," he twice supported the candidacy of the radical republican Whig Algernon Sidney for parliament. At Guildford and later at Bramber in 1679 he campaigned vigorously but unsuccessfully for his friend, drawing down upon himself the criticism of those Quakers who considered such activity unsuitable for one of their religious profession. During these years he also wrote a number of pamphlets on behalf of the radical Whigs. *England's Great Interest in the Choice of This New Parliament* (1679) is especially noteworthy as one of the first clear statements of party doctrine ever laid before the English electorate.

Settlement of Pennsylvania.—Even before this excursion into English politics, he had become involved in American colonization as a trustee for Edward Byllynge, one of the two Quaker proprietors of West New Jersey. Though recent scholarship tends to give Byllynge the major credit for writing the "Concessions and Agreements" of West New Jersey, there is no doubt that Penn had a hand in making it the remarkable democratic and libertarian document it is. In 1681 he and 11 other Quakers bought the proprietary rights to East New Jersey from the widow of Sir John Carteret. In the same year, discouraged by the untoward turn of political events in England, where Charles II was ruling without parliament and prospects for religious freedom seemed dark, he sought and received a vast province on the west bank of the Delaware river, which was named Pennsylvania for his father (to whom Charles II had owed a large debt cancelled by this grant). A few months later the duke of York granted him the three "lower counties" (later Delaware). In Pennsylvania Penn hoped to provide a refuge for Quakers and other persecuted people and to erect an ideal Christian commonwealth. "There may be room there, though not here," he wrote to a friend in America, "for such a holy experiment."

The fundamental law of this "holy experiment" was to be the Sermon on the Mount, whose principles the Quakers construed not as counsels of perfection but as practical guides to life. As proprietor, Penn was free to create a government which should embody his Quaker-Whig ideas. In drawing up the Frame of Government he intended, he said, to leave himself and his successors "no power of doing mischief, that the will of one man may not hinder the good of a whole country." Freedom of worship was, of course, to be absolute, and all the traditional rights of Englishmen were carefully safeguarded. The actual machinery of government outlined in the Frame proved in some respects clumsy and unworkable, but he wisely included an amending clause—the first in any written constitution—so that it could be altered as necessity required.

Penn himself sailed for his province late in 1682 in the "Welcome," leaving his family behind. He found his experiment well under way. The city of Philadelphia was already laid out as a "green country town" on a gridiron pattern according to his instructions and settlers were pouring in to take up the fertile lands lying around it. Presiding over the first assembly, he saw the government of the "lower counties" united with that of Pennsylvania and the laws "agreed upon in England" incorporated in the "Great Law" of the province. In a series of treaties based on mutual trust he established good relations with the Leni-Lenape Indians. (Benjamin West's famous painting of the "Great Treaty" at Shackamaxon, however, must be regarded as an exercise of the historical imagination.) He also held an unsuccessful conference with Lord Baltimore, proprietor of the neighboring province of Maryland, to negotiate a boundary line. This boundary was to remain a bone of contention for more than half a century; in 1684, after only two years in his colony, he was obliged to go back to England to defend his interests against Baltimore.

Before his return, he published *A Letter to the Free Society of Traders* (1683), containing his fullest description of Pennsylvania and including a valuable account of the Leni-Lenape, based on firsthand observation. With the accession of his friend the duke of York as King James II, he found himself in a position of great influence at court, whereby he was able to have hundreds of Quakers, as well as political prisoners such as John Locke, released from prison. When James issued his Declaration of Indulgence in 1687, Penn welcomed it, though this attitude laid him open to criticism, since the declaration provided only for the toleration of dissent at the royal pleasure, not as a matter of fundamental right. But the Act of Toleration (1689), passed after James's abdication, finally established the principle for which Penn had laboured so long and faithfully.

His close relations with James brought him under a cloud when William and Mary came to the throne. His colony was temporarily (1693–94) taken from him, and for a time he was forced to live virtually in hiding to avoid arrest. He used this period of enforced retirement to write some of his most charming and thoughtful books. Among other works he produced *An Essay Towards the*

Present and Future Peace of Europe (1693), in which he proposed an international organization to prevent wars by arbitrating disputes; *Some Fruits of Solitude* (1693), a collection of religious and practical maxims which Robert Louis Stevenson was to praise, two centuries later, as a "sweet, dignified, and wholesome book"; and *The Rise and Progress of the People Called Quakers* (1694), the earliest effort to set down the history of the Quaker movement. He also drafted (1696) the first plan for a union of the American colonies.

In 1696, his first wife having died, he married Hannah Callowhill of Bristol, by whom he had seven children, five of whom lived to adulthood. Meanwhile, affairs had been going badly in Pennsylvania. The assembly quarreled constantly with the council and with Penn's deputy governors. The "lower counties" were unhappy at being unequally yoked with the larger province. Relations with the home government were strained by the Quakers' conscientious refusal to provide military defense. And the quitrents, by which the proprietor hoped to gain an income from his province, proved almost impossible to collect. In 1699 the proprietor with his wife returned to his province and took up residence at Pennsbury, his handsome country seat on the Delaware, north of Philadelphia (now reconstructed by the commonwealth of Pennsylvania). He contrived to settle many of the outstanding difficulties and in 1701 promulgated a revised constitution, known as the charter of privileges, under which legislative power was vested in a single-chamber assembly. This democratic instrument of government was to remain in force until 1776. After less than two years his affairs at home once more demanded his presence and he left the province, never to see it again. His Pennsylvania interests he left in the capable hands of his secretary, James Logan, who upheld them loyally for the next half century.

Retirement and Death.—Penn's final years were unhappy. His eldest son, William Jr., turned out a scapegrace. His own poor judgment in choosing his subordinates (save for the faithful Logan) recoiled upon him: his deputy governors proved incompetent or untrustworthy, and his steward, Philip Ford, cheated him on such a staggering scale that he was forced to spend nine months in debtors' prison. In 1712, discouraged at the outcome of his "holy experiment," he commenced negotiations to surrender Pennsylvania to the crown, saving only the precious principle of religious freedom. A paralytic stroke, which seriously impaired his memory and dulled his once-keen intellect, prevented the consummation of these negotiations. He lingered on, virtually helpless, until 1718, his wife undertaking the management of his proprietary concerns. He died July 30, 1718, and was buried at Jordans in Buckinghamshire.

Penn's collected works were published in 1726 (reprinted 1771, 1782, 1825). *The Witness of William Penn*, edited by Frederick B. Tolles and E. Gordon Alderfer in 1957, is an anthology of his writings.

BIBLIOGRAPHY.—Samuel M. Janney's *Life of William Penn* (1850) is still valuable, especially for its many excerpts from Penn's letters. Three useful modern biographies are William I. Hull's *William Penn: a Topical Biography* (1937); William Wistar Comfort's *William Penn 1644–1718: a Tercentenary Estimate* (1944); and Catherine Owens Peare's narrative *William Penn* (1957). (F. B. T.)

PENNANT, THOMAS (1726–1798), Welsh naturalist and traveler, whose *British Zoology* (1766 *et seq.*) gave a strong impetus to zoological and particularly ornithological work in Great Britain, was born on June 14, 1726, at Downing, Flintshire. Pennant has been called the leading British zoologist since John Ray and before Charles Darwin. According to Samuel Johnson he was "the best traveller I ever read; he observes more things than anyone else does." Pennant's portrait by Thomas Gainsborough is in the National Museum of Wales, Cardiff. He died at Downing on Dec. 16, 1798.

His *Synopsis of Quadrupeds* (1771) was later enlarged into a *History of Quadrupeds* (1781). The *Arctic Zoology* was published in 1784–87. His travel books, all containing valuable information on local customs, natural history, and antiquities, include the *Tour in Scotland in 1769* (1771), followed by an account of another Scottish tour (1774); *A Tour in Wales* (1778), the second edition of which (1784) incorporated the *Journey to Snowdon;* and *The Journey from Chester to London* (1782). His *Tour on the Continent* describes a journey in 1765 when he met G. L. Buffon, P. S. Pallas, and other eminent naturalists, as well as Voltaire. It remained in manuscript until published by the Ray Society in 1948. Other works include his popular *London* (1790) and *Outlines of the Globe* (unfinished). Pennant took no degree while at Oxford; but academic honours conferred later included membership of the Royal Society of Uppsala (1757), fellowship of the Royal Society (1767) and doctor of civil law of Oxford (1771). Among his many correspondents in Great Britain and abroad was Gilbert White, whose *Natural History of Selborne* is largely in the form of letters to Pennant. (C. MN.)

PENNELL, JOSEPH (1857–1926), U.S. etcher, lithographer, and writer, was born in Philadelphia, Pa., on July 4, 1857, and first studied there and in Germantown. Like his compatriot and friend, J. M. Whistler, he afterward went to Europe and made his home in London. He produced numerous books (many of them in collaboration with his wife, Elizabeth Robins Pennell), but his chief distinction is as an original etcher and lithographer, and notably as an illustrator. He contributed, indeed, more than any other artist of his period to the art of illustration. During his lifetime Pennell produced more than 900 etchings and mezzotints and more than 600 lithographs, on subjects ranging from the Panama Canal and Yosemite National Park to the factories of England and the temples of Greece. His publications include *Pen Drawing and Pen Draughtsmen* (1889), *Lithography and Lithographers* (1898), a biography of Whistler, with Mrs. Pennell (1908), *Etchers and Etching* (1919), and *The Adventures of an Illustrator* (1925). Pennell moved back to the United States during World War I and died in Brooklyn, N.Y., on April 23, 1926.

See E. R. Pennell, *Life and Letters of Joseph Pennell* (1929).

PENNEY, SIR WILLIAM GEORGE (1909–), English physicist, known for his work in the field of atomic weapons, was born on June 24, 1909, and educated in the technical school, Sheerness, and the Royal College of Science, London University. After holding research fellowships and exhibitions at Wisconsin University (1931–33) and at Trinity and Pembroke colleges, Cambridge, he was assistant professor of mathematics at the Imperial College of Science and Technology, London University (1936–45). He was elected fellow of the Royal Society in 1946. During World War II, he was engaged in scientific work for the Ministry of Home Security and the Admiralty; and in 1944–45, he was principal scientific officer of the department of scientific and industrial research at the Los Alamos Laboratory, N.M. In 1946–52, he was chief superintendent of armament research, Ministry of Supply. He was created a knight of the British empire (1952), was made director of atomic weapons research and development at Aldermaston, Berkshire (1953), and became deputy chairman of the U.K. Atomic Energy Authority in 1961. His publications include many papers on the theory of molecular structure. (D. MCK.)

PENNINES, an extensive system of hills in the north of England formed by an upfold of Carboniferous rocks running southward from the Scottish border into Derbyshire. The name is probably derived from the Celtic *pen*, "high." On the north a well-marked depression, falling below 500 ft. in height, between the lower valleys of the Irthing and the South Tyne, from which it is known as the Tyne Gap, separates the Pennines from the Cheviots. On the northwest the Eden Valley falls between the Pennines and the hills of the Lake District, and the division is continued by the upper valley of the Lune. For the rest the physical boundaries consist of extensive lowlands—on the east the vale of York, on the west the coastal belt of Lancashire and the plain of Cheshire, and on the south and southeast the valley of the Trent River. The Pennines thus cover parts of Cumberland, Westmorland and Northumberland, Lancashire, Yorkshire and Durham, Cheshire and Derbyshire, while the southern foothills extend into Staffordshire and Nottinghamshire.

The Pennine system is often wrongly called a chain, but it is hardly even a range. The hills are broken up into numerous short ranges by valleys cut back into them in every direction, for the

Pennines form a north and south watershed which determines the course of all the larger rivers in the north of England. They are divided into two sections by a gap formed by the Aire River flowing east and the Ribble flowing west. To the north of this gap rise the Craven Uplands and to the west Bowland Forest.

The northern section of the Pennine system is broader and generally higher than the southern. Its western slope is generally short and steep, the eastern long and gradual, this distinction applying to the system at large. In the northwest a sharp escarpment overlooking the Eden Valley is known as the Cross Fell Edge from its highest point, Cross Fell (2,930 ft. [893 m.]), to the southeast of which a height of 2,780 ft. (847 m.) is reached in Milburn Forest and of 2,591 ft. (790 m.) in Mickle Fell. This range is marked off eastward by the upper valleys of the South Tyne and the Tees. In the northern section the highest points are Cross Fell, Whernside (2,419 ft.), Ingleborough (2,373 ft.), and Penyghent (2,273 ft.), and in the southern Kinder Scout (2,088 ft.) which includes the Peak. It is seen that the higher elevations, like the steeper slopes, lie toward the west. The hills between the Lune Valley on the west and the headstream of the Eden and the Ribble on the east are broken into masses by the dales of tributaries to the first-named river. The Ribble and Eden valleys afford a route for the railway between Settle and Appleby. Well-marked eastward ranges occur there between Swaledale and the Ure River, which traverses Wensleydale, and between the Ure and Wharfe. In the first the highest points are High Seat (2,328 ft.) and Great Shunner Fell (2,340 ft.); and in the second Buckden Pike (2,302 ft.) and Great Whernside (2,310 ft.). There is then a general southerly slope to the Aire Gap.

In the southern section heights above 2,000 ft. are rare; the centre of the section is the well-known Peak of Derbyshire. Throughout the system the structure is of Carboniferous limestone and millstone grit with some local shales between. The drier parts of the hills are covered with heather moor while the wet peaty areas are covered mostly with cotton grass. Where the limestone has been exposed, as in the limestone pavement of Ingleborough, the surface is bare except in the fissures where there is a luxuriant vegetation. The summits of the hills are rounded or nearly flat so that the profile of the Pennines is not striking as a rule, but much fine scenery is found in the narrow dales throughout—Wensleydale, Wharfedale, and other Yorkshire dales. The population in the uplands is scanty, though some sheep are kept. There are many farms in the fertile dales and valleys. In the parts about Settle below Ingleborough, in Derbyshire and elsewhere remarkable caverns and subterranean watercourses in the limestone have been explored to great depths. In Ingleborough itself are the Ingleborough Cave, near Clapham; the chasm of Gaping Gill, more than 350 ft. deep; Helln or Hellan Pot, a vast swallow hole 359 ft. deep, only exceeded by Rowten Pot (365 ft.) near Whernside; and many others. Malham Tarn, near the head of the Aire, is drained by a stream which quickly disappears below ground, and the Aire itself is fed by a brook gushing forth in full stream at the foot of the cliffs of Malham Cove. A notable example in Derbyshire is the disappearance of the Wye into Plunge Hole, after which it traverses Poole's Cave, close to Buxton. There may also be noted the remarkable series of caverns near Castleton. Lakes are few and small in the Pennines but there are reservoirs for the supply of the populous manufacturing districts of Lancashire and the West Riding of Yorkshire. The Pennines are much visited by vacationers, among them many climbers and walkers who use the Pennine way, a 250-mi. (402 km.) footpath running along the hills from end to end.

Prehistoric remains are numerous, the great circle at Arbor Low being one of the best known. The Romans left many traces, chief among them being Hadrian's Wall (*q.v.*) which was built across the northern Pennines from Carlisle to the mouth of the Tyne and part of which stands on the Whin Sill. *See* ENGLAND; CUMBERLAND; YORKSHIRE; etc.

PENNS GROVE, a borough of New Jersey in Salem County on the Delaware River opposite Wilmington, Del. Originally a part of Upper Penns Neck Township, the settlement developed around a riverboat landing. By 1830 it consisted of eight dwellings, a tavern, and a store and was a daily point of call for the Wilmington-Philadelphia steamboat. In 1876 the railroad entered the town from Woodbury, and in 1894 Penns Grove became a separate borough. Its subsequent growth was stimulated by the expansion of the Du Pont industries, whose gunpowder plant was started in 1891 immediately south of Penns Grove and whose dye works were established in 1917, the year a trolley line was built from Salem. Afterward, lead-ethyl plant expansion was a further source of employment. For comparative population figures *see* table in NEW JERSEY; *Population.* (H. F. WI.)

PENNSYLVANIA, popularly known as the "Keystone state" because of its central position among the 13 original states, is one of the four states of the U.S. which are officially styled commonwealths. It is bounded north by Lake Erie and New York; east by New York and New Jersey; south by Delaware, Maryland and West Virginia; and west by the Panhandle of West Virginia and by Ohio. Thirty-third among the 50 states in size, Pennsylvania has a total area of 45,333 sq.mi. (117,413 sq.km.), of which 326 sq.mi. (844 sq.km.) are water surface. The state capital is at Harrisburg (*q.v.*). Pennsylvania's state flower is the mountain laurel, the state tree is the hemlock and the state bird is the ruffed grouse. The name, meaning "Penn's woods," was given by Charles II of England in honour of Adm. William Penn, father of William Penn, the founder of the colony.

PHYSICAL GEOGRAPHY

Physical Features.—Pennsylvania is in the form of a rectangle lying between latitude 39° 43′ (the Mason and Dixon line) and 42° N. and longitude 74° 43′ and 80° 31′ W. of Greenwich, with three exceptions: a triangular projection to latitude 42° 16′ N. gives it almost 40 mi. of Lake Erie shore line; two large bends of the Delaware river cut deeply into New York and New Jersey; and an unusual semicircular boundary separates it from Delaware.

The state has five principal physiographic divisions: the coastal plain, the older Appalachians, the newer Appalachians, the Allegheny plateau and a small part of the Lake Erie plain. The Appalachian mountain system, which curves across the state from southwest to northeast, is the most prominent feature of its topography. The state varies in height from sea level on the Delaware river to 3,213 ft. (979 m.; Mt. Davis) in Somerset county. At the extreme southeast the coastal plain touches Pennsylvania in a narrow belt along the Delaware near Philadelphia (*q.v.*).

The southeast province of the older Appalachians includes the piedmont with its limestone lowlands in Chester, Lancaster and York counties and Triassic lowlands extending from Bucks county to Adams county. The northern edge of this province is a discontinuous line of uplands and hills which rise to become South

mountain a few miles west of the Susquehanna river, reach an elevation of 2,100 ft. at the Maryland border and continue southward as the Blue Ridge.

A region of ridges and valleys lying beyond South mountain and its related uplands, bordered on the northwest by the high eastern edge or front of the Allegheny plateau, is known as the newer Appalachians or the central province. This province has two main subdivisions, the Great valley and the ridge and valley section, separated by the long ridge of Kittatinny or Blue mountain. The Great valley, locally called the Lehigh, Lebanon or Cumberland valley, is 12 to 20 mi. wide and 120 mi. long. The ridge and valley section, which parallels it with a width of 45 to 70 mi., is notable for ridges of considerable length and uniformity of crest lines, broken only by an occasional V-shaped wind gap, a narrow water gap or a rounded knob, and for long parallel valleys usually only a few miles wide.

In the northeast the newer Appalachians meet the Pocono plateau, a part of the Allegheny plateau which continues on to form the Catskill plateau in New York. The Allegheny plateau extends from the Allegheny front to and beyond the south, west and north borders of the state, and includes the state's highest elevations.

Nearly all of the southeast and central provinces and the northeast portion of the Allegheny plateau are drained by the Susquehanna and Delaware river systems into Chesapeake and Delaware bays. The greater part of the Allegheny plateau is drained by the Allegheny and Monongahela rivers into the Ohio. Tributaries of the Potomac drain a small part of the southeast and central provinces; the Lake Erie plain is drained by short streams into the lake; and a small section of the Allegheny plateau in northern Potter county is drained by the Genesee river into Lake Ontario.

The Susquehanna, which drains almost half of the state, is a wide, shallow stream with numerous islands. At Northumberland it forks into two major tributaries, the North branch and the West branch, both with zigzag courses. The Susquehanna and the Delaware and their principal tributaries flow for the most part transverse to the geological structure. The gorges and water gaps through which they pass in the mountain region provide some of Pennsylvania's most picturesque scenery. The gorges are also of great economic importance as passages for railways and highways. As a result of the sinking of the coastal plain the sea has entered the lower portion of the Delaware river, making a tidal estuary at the head of which the port of Philadelphia developed.

The Allegheny and Monongahela, after following southwesterly and northwesterly courses, join to form the Ohio river at Pittsburgh (*q.v.*). They are of economic importance for transportation in the western Pennsylvania industrial region, and the Ohio river makes Pittsburgh the state's second port.

Climate.—Since the prevailing winds are from the west, Pennsylvania has what is called a humid continental type of climate with extremely variable weather, but with rainfall usually adequate for most crops grown in its latitude. Climatically speaking, there are two regions: one with long summers and mild winters in the southeast and in the Ohio-Monongahela valley, and one with short summers and severe winters in the Allegheny plateau and the north. The mean annual temperature is about 52° F. (about 11° C.) in the southeast, 50° F. in the centre, 47° in the northwest and 49° on the shore of Lake Erie. Temperatures over 100° and below zero have been recorded in the long-summer region, while the short-summer region sometimes has daytime summer temperatures over 90°, although the nights are cool. The summer maxima on the mountains are usually 8° to 10° less than in the valleys directly below them. The average annual rainfall is 42 in.

Soil.—In keeping with its topography, Pennsylvania has many types of soil. The limestone soils of the Lancaster plain, the southeastern part of the Great valley and the valleys of the ridge and valley section are the best for agriculture, although there are some good limestone soils in the southwest. The alluvial soils along the river valleys are also good. In other parts of the state where sandstone and shale predominate the soils are less fertile, varying from good to poor.

Vegetation.—Originally Pennsylvania was covered with forests, but the settlers cleared their farms, the charcoal iron furnaces used vast quantities of timber and finally great lumbering operations in the latter part of the 19th century cut down virtually the last of the original stands. In 1897 the state began the purchase of forestry reserves, and from this grew the department of forests and waters with its scientific forest conservation program, of which Gifford Pinchot (*q.v.*) was a leader. Trees were planted, seedlings provided to private land owners and forest fires fought.

By the 1960s the total forest area of Pennsylvania amounted to more than 15,000,000 ac. or over half the area of the state. More than 1,870,000 ac. were in state forest, 470,000 ac. in national forest, 900,000 ac. in state game land and about 11,000,000 ac. in privately owned woodland which included farm woodland. On the higher elevations the trees are mostly white pine, yellow pine and hemlock, but in the valleys oaks, hickories, maples, locusts and birches predominate. Beautiful smaller trees and shrubs include the dogwood and the mountain laurel. Among the wild flowers are hepatica, wild honeysuckle, trillium, dog's-tooth violet and anemone.

Animal Life.—The primeval forest of Pennsylvania was rich in animal and bird life. Elk, moose, deer, black bear, panthers, wildcats, wolves and passenger pigeons were abundant. The protection and restoration of wildlife was a part of the conservation movement in the state. The state game commission opened its first game refuge in 1905 and by the purchase of game lands, the licensing and regulation of hunting and the propagation of game birds and animals it has greatly increased the wildlife resources of the state. The black bear was saved from extinction and is now fairly common in mountain regions, the white-tailed deer was restocked, and smaller animals such as raccoons, squirrels, rabbits, skunks and woodchucks are common. Wild ducks and geese,

ruffed grouse, quail, pheasants and turkeys are among the game birds. The fish commission protects and propagates fish, stocking streams and regulating and licensing fishermen. Consequently, hunting and fishing have remained major sports in Pennsylvania.

State Parks and Recreation.—In keeping with the increased interest in outdoor recreation, the state has developed an elaborate system of parks and recreation areas. There are more than 125 parks, forest picnic areas, forest monuments and historical parks. More than 3,000 mi. of roads and 4,000 mi. of marked trails have been constructed by the state in developing such sites as Hickory Run northeast of Hazleton, a 12,721-ac. forested tract, and Pymatuning north of Jamestown where a 17,000-ac. lake originally designed to supply water to industry is open to boaters and fishermen. The historical parks include famous sites such as Valley Forge, where Washington's army spent the winter of 1777–78, and

HISTORY

The country along the lower Delaware river was disputed by the English, Dutch and Swedes in the early days of exploration, trade and settlement. Henry Hudson, an Englishman in the service of the Dutch, entered Delaware bay in 1609. Subsequently both the Dutch and the English traded along the river and established temporary posts in what is now Pennsylvania, but the Swedes were the first to make a permanent settlement, an expansion of settlements which they had begun in Delaware in 1638. In 1643 Johan Printz, a governor of New Sweden, built a fort on Tinicum Island (at Essington) which he called New Gothenborg. Another settlement was soon established at Upland (renamed Chester by William Penn), and other small farming settlements grew up along the river. Since Finland was then under the Swedish crown, Finns made up a large proportion of the settlers. The Dutch seized the Swedish colony in 1655, but were in turn dispossessed by the English who took over their colonies in 1664 as a grant to the duke of York. The Duke's Laws were put into operation along the Delaware and a court was established at Upland. The Swedish and Finnish settlers remained as a nucleus for Penn's colony.

The Quaker Colony.—William Penn (*q.v.*) and other Quakers early became interested in a colony in America for Quakers suffering persecution in England under the so-called Clarendon code. Despite his Quaker beliefs Penn was in good standing with Charles II and his brother the duke of York, later James II, because of the services of his father, Adm. William Penn (*q.v.*). Furthermore, the younger William had inherited a substantial claim against the crown. In 1680 he petitioned for a grant of land for a colony, the duke supported his petition and on March 4, 1681, Charles II granted the charter. Penn was made proprietary of the lands, but the laws of England were to be applicable in the colony until replaced by new laws adopted with the consent of the freemen and subject to review by the crown. Penn granted several successive "frames of government" or constitutions, gradually increasing the powers of the elected assembly until the Charter of Privileges in 1701 gave it more privileges and powers than any other legislative body in the English colonies. In keeping with the purpose of his colony, provisions guaranteeing religious freedom were embodied in its first law code, the Great Law, adopted Dec. 7, 1682. All Christians holding certain amounts of property were eligible as voters and officeholders.

Penn sent commissioners to lay out, in a regular pattern, a "great town" which he named Philadelphia ("city of brotherly love"). In an advantageous location between the Delaware and Schuylkill rivers, the city grew rapidly in population and prosperity. The first assembly was held at Chester in 1682, soon after Penn's arrival in the colony, but Philadelphia was thereafter the seat of the government. Penn maintained a friendly and peaceful policy toward the Indians, taking care to purchase their claims before surveying and settling lands. Of the many treaties which he held with them the most famous was the "Great treaty" of Shackamaxon, according to Voltaire "the only treaty not sworn to and never broken." This policy of fair dealing preserved Pennsylvania from Indian hostilities during Penn's lifetime and indeed until 1755.

In 1692, following the fall of James II and the accession of William and Mary, Penn was removed from the governorship and the colony was placed under the rule of Gov. Benjamin Fletcher of New York. Penn was reinstated, however, in 1694. Except during his two visits, in 1682–84 and 1699–1701, he and his heirs governed through deputy or lieutenant governors bound by detailed instructions and advised by a provincial council. After Penn suffered a stroke in 1712 his wife Hannah acted as proprietary, first for him until his death in 1718 and then for their children, John, Thomas and Richard, until her own death in 1727. John, who had a half interest, died in 1746, and Thomas Penn then became the chief proprietary until his death in 1775. Thomas Penn was a shrewd and somewhat narrow man who lacked his father's idealism and took an interest in the colony chiefly for the financial return it brought him. Two sons of Richard Penn were the last lieutenant governors of the colony, John Penn in 1763–71 and 1773–76 and Richard Penn in 1771–73. John Penn continued to live in Pennsylvania until his death in 1795.

Colonial Immigration.—The liberal and tolerant principles of Pennsylvania's government attracted a constantly increasing flow of immigrants, not only from the British Isles but also from the Rhine country of Germany. Some came for refuge from intolerance, oppression and war; others came to seek a better living in a new country, lured by the enthusiastic pamphlets which Penn had circulated widely. English Quakers were the dominant element to the time of the Revolution, but Welsh Quakers came in large numbers before 1700, a large colony settling in the "Welsh barony" in Montgomery and Delaware counties. The southeastern counties became predominantly English.

German immigration began with the Mennonite Francis Daniel Pastorius, who came to Pennsylvania with some Dutch Quakers in 1683 and founded Germantown (*q.v.*), the pioneer German settlement. The earlier German settlers were for the most part members of the smaller sects who came and settled as groups; they included the Mennonites, Amish, Dunkers or German Baptists, Schwenkfelders and Moravians. After 1727 the volume of German immigration greatly increased but then it consisted mainly of "church people," members of the Lutheran and Reformed churches who were thus distinguished from the smaller "sects." The Pennsylvania Dutch, as they came to be called, predominated in Northampton, Berks and Lancaster counties and adjacent areas. Their farming skills made this region a rich agricultural area and helped to increase the prosperity of the colony. By the time of the Revolution they numbered about 100,000, more than a third of the population.

The third important element in the colony's population was the Scotch-Irish who began to immigrate in numbers about 1728. A hardy, restless, pioneering people, they naturally gravitated to the frontier, pushing forward the area of settlement into the Cumberland valley and southwestern Pennsylvania. Because they differed from the Quakers and the Germans in temperament and in the problems which they faced on the frontier, they formed an opposition to the ruling Quaker element throughout the 18th century. They numbered about 70,000 by the end of the colonial period.

There was also a considerable amount of remigration from other colonies, with Marylanders settling in York county, Virginians moving into southwestern Pennsylvania and Connecticut "Yankees" settling in the beautiful Wyoming and Muncy valleys on the North branch of the Susquehanna after 1770.

This remigration reflected to some extent the serious boundary disputes with Maryland, Virginia and Connecticut. After a long period of litigation, the boundary between Maryland and Pennsylvania was surveyed in 1763–67 by Charles Mason and Jeremiah Dixon, and this Mason and Dixon line (*q.v.*) later became significant as separating the free and the slave states. Farther west, Virginia laid claim to southwestern Pennsylvania and the two colonies established rival county governments in the area in the 1770s. In 1779 a joint commission was set up, and it was decided that the Mason and Dixon line should be extended to a point five degrees west from the Delaware river, with the western boundary extending thence due north to Lake Erie. Connecticut's claim to the northern third of Pennsylvania arose out of the vague language of its sea-to-sea charter, but it was promoted by a private association called the Susquehanna company, organized in 1753. Vigorous efforts to settle the Wyoming valley gave rise to the so-called Yankee-Pennamite wars of 1769–75. During the Revolution a special court of arbitration set up by the Continental Congress decided in favour of Pennsylvania's claim in the Trenton decree, 1782. The boundary with New York, surveyed in 1786–87, caused no serious dispute. In 1792 Pennsylvania bought the Erie triangle, the small triangular strip north of the 42nd parallel, from the federal government in order to have a port on Lake Erie.

Colonial Politics.—The natural conflict between the proprietary and popular elements of the colony's government led to sharp political controversy, in which Benjamin Franklin after 1740 became the leader of the Quaker or popular party. This party, which usually controlled the assembly, contended for the right to tax proprietary lands, to issue paper money and to control expenditures; and one after another the governors went down to defeat. These party battles, which taught Pennsylvanians the art of politics, did not interfere with the colony's rapid economic and cultural growth, however.

Pennsylvania led the colonies in the production of cereals, hay and livestock, and had a surplus for export. The lumber, textile, shipbuilding and iron industries made early beginnings. Printing and publishing began in 1686, and the first paper mill was erected by William Rittenhouse before 1693. By 1775 the colony had nine newspapers. Strategically located to draw upon the resources of Pennsylvania, western New Jersey and Delaware, the merchants of Philadelphia developed an extensive foreign trade, and the city rapidly became a commercial metropolis. The cultural and intellectual life of the colony kept pace with its material prosperity. Science and invention, medicine and the arts made notable progress. Architecture flowered in such public buildings as the statehouse (later called Independence hall) and in the fine colonial mansions of the Philadelphia area. The American Philosophical society, one of the world's oldest learned societies, was founded in Philadelphia in 1743, and the University of Pennsylvania dates back to the same period.

The French and Indian War.—The peaceful development of the colony was interrupted by the conflict between France and Great Britain for possession of the Ohio valley, where Pennsylvania and Virginia traders had begun to trade with the Indians as early as the 1720s. The French, who considered the Ohio river an essential link between their colonies of Canada and Louisiana, became alarmed by the British penetration and especially by the formation of the Ohio Company of Virginia to exploit the lands in southwestern Pennsylvania, then claimed by Virginia. As a result, the French in 1753 began building a line of forts to secure possession of the valley, of which the first were Ft. Presque Isle (at present Erie) and Ft. Le Boeuf (at Waterford, Erie county). After sending George Washington to Ft. Le Boeuf in Dec. 1753 to warn the French against encroaching on British territory, Virginia prepared to build a fort at the forks of the Ohio where the city of Pittsburgh now stands. In April 1754 a French expedition drove away the Virginia workmen and built Ft. Duquesne on the site. An expedition led by Washington defeated a French scouting party, but was later besieged by a stronger French force at the hastily erected Ft. Necessity and compelled to surrender. The British then sent an army under Gen. Edward Braddock against Ft. Duquesne, but on July 9, 1755, at the battle of the Monongahela, Braddock's army was cut to pieces by a smaller force of French and Indians. In the same year the French built Ft. Machault at Venango (present Franklin) to strengthen their communications.

Cut off from their usual trade with the British, impressed by French successes and perhaps recalling some old grievances about sales of land, the Indians took the French side and began raiding Pennsylvania's outlying settlements. To protect the settlers the Pennsylvania government built a line of forts, and even staged a successful raid against the Indian village of Kittanning on the Allegheny (1756). In 1758 an expedition under Gen. John Forbes was successful in taking Ft. Duquesne, and in 1759 the capture of Ft. Niagara by Sir William Johnson compelled the French to evacuate their other forts on Pennsylvania soil. When Forbes took possession of the ruins of Ft. Duquesne he named the place Pittsburgh in honour of the British prime minister, and a new fort was built there and called Ft. Pitt. (*See* also FRENCH AND INDIAN WAR.)

In 1760 the forts in northwestern Pennsylvania were rebuilt, but they were taken and destroyed by the Indians in 1763 at the outbreak of Pontiac's War, and Ft. Pitt was besieged. Col. Henry Bouquet defeated the Indians in a two-day battle at Bushy Run and relieved Ft. Pitt. The next year he led a bloodless but impressive expedition into Ohio as far as the Muskingum river and compelled the Indians to sue for peace. As a result, southwestern Pennsylvania was opened to settlement, which proceeded rapidly and made the area the first important trans-Allegheny extension of the American colonies.

Pennsylvania and the Revolution.—Pennsylvania's opposition to the Stamp act and other tax measures by which Britain sought to raise revenue from the colonies was strong but quiet in its expression. Philadelphia merchants adopted nonimportation agreements, and John Dickinson (*q.v.*) wrote the famous *Letters From a Farmer in Pennsylvania* in defense of American rights. In 1770 Philadelphia citizens refused to permit a tea ship to unload its cargo, but there was no demonstration like the Boston "tea party" and the vessel returned to England. After the so-called Coercive acts were passed to punish Boston, protest meetings were held in Pennsylvania, and an extralegal government by committees of correspondence and committees of safety gradually took shape after 1774.

Pennsylvania's attitude in the dispute with the mother country was of great importance because of its resources and central loca-

tion. The opposition of many Quakers, Dunkers and Mennonites to war and revolution, the loyalty of the Church of England minority to Britain and the disinterest of the German population made Pennsylvania's position doubtful. The Scotch-Irish on the frontiers strongly favoured independence, however, and the fact that the first and second Continental Congresses met in Philadelphia (1774 and 1775–83) also helped Pennsylvania's revolutionary leaders. After the adoption of the Declaration of Independence, which Pennsylvania's delegation supported by only a narrow majority, a provincial convention met in Philadelphia, took over the government and wrote a state constitution which went into effect in Sept. 1776 without being submitted to a vote of the people. This constitution provided for an assembly of one house and for a multiple executive, the supreme executive council, which consisted of 12 members, one elected from each county and one from the city of Philadelphia. By a joint vote the two bodies annually elected a president of the council, who was titular head of the government. Existing inequalities in representation were corrected in favour of the western counties, and the suffrage was extended to all freemen who paid taxes. The Revolution in Pennsylvania was more than a break with Britain; it marked the end of Quaker dominance in the government.

Under the leadership of Joseph Reed and George Bryan the new radical government ruled with a strong hand, disfranchising the opposition by a test act and even confiscating the estates of suspected loyalists. It contributed greatly to the success of the Revolutionary War by furnishing troops and supplies. By the divesting act of 1779 the Penn heirs were deprived of the proprietary lands, although they were allowed to keep the estates or manors which had been surveyed and were further compensated by a grant of £130,000, which was paid after the end of the war. The most lasting achievement of the radicals was the passage of the gradual emancipation act of March 1, 1780, which provided that no child born in Pennsylvania after that date should be a slave. Thus slavery was ended in a generation. While the radicals ruled the state, conservatives aided the Revolutionary cause in congress and the army. Robert Morris organized congressional finances, raising money when others failed. Dickinson wrote many important documents, among them the Articles of Confederation. Anthony Wayne was the most brilliant of the generals from Pennsylvania.

Some important campaigns of the war were fought on Pennsylvania soil (*see* AMERICAN REVOLUTION). Toward the end of the Revolution, a political reaction began which eventually brought the conservatives to power, and they confirmed their gains by repealing the test act. In spite of strong radical opposition, they secured Pennsylvania's ratification of the federal constitution on Dec. 12, 1787, and went on in 1790 to draft a second state constitution. The supreme executive council was abolished, the office of governor was restored with extensive powers and a two-house legislature was established. From 1790 to 1800 Philadelphia, then the largest and wealthiest city in the United States, was the seat of the federal government.

Pennsylvania to the Civil War.—Under Gov. Thomas Mifflin (1790–99) Pennsylvania at first supported the Federalist party, and the state aided in suppressing the Whisky rebellion in western Pennsylvania (1794) and the "Hot Water rebellion" in eastern Pennsylvania (1799), both directed against unpopular federal taxation. The rising opposition elected Thomas McKean governor in 1799, and from then until 1860 the Democrats were the majority party, even though intraparty quarrels sometimes gave victory to their opponents. The westward movement of population and agrarian distrust of the metropolis moved the capital from Philadelphia to Lancaster in 1799, and from Lancaster to Harrisburg in 1812.

After the Revolution settlement increased beyond the mountains in western Pennsylvania. Purchases from the Indians at Ft. Stanwix (1784), Ft. McIntosh (1785) and Ft. Harmar (1789) opened northwestern Pennsylvania to settlers, a large part of these lands being granted to veterans. The upper Susquehanna valley also had many settlers in this period. In 1800 the state's population reached 602,000. The extension of settlement led to a demand for better communications, and there was a widespread campaign for internal improvements. Roads were extended to all parts of the state, and many bridges were built. The first important turnpike in America was the Philadelphia-Lancaster turnpike, completed in 1794, and by 1832 about 3,000 mi. of road had been built by 220 turnpike companies. The building of canals began in 1797, but the first long canal was the Union canal, completed in 1827 between Middletown on the Susquehanna river and Reading on the Schuylkill. In 1826 the state undertook to build a line of "state works" from Philadelphia to Pittsburgh, with the Allegheny portage railroad and the Columbia and Philadelphia railroad serving as links in the canal system. This was opened for traffic in 1834. Numerous branch canals were also built. The canals greatly benefited the economic development of the state, but they were ruinously expensive and created such a burden of debt that they were sold between 1843 and 1858, and later abandoned when railroads took their place. The early railroads were mainly short lines to carry coal from the mines to canals or rivers, but they eventually developed into a great transportation network.

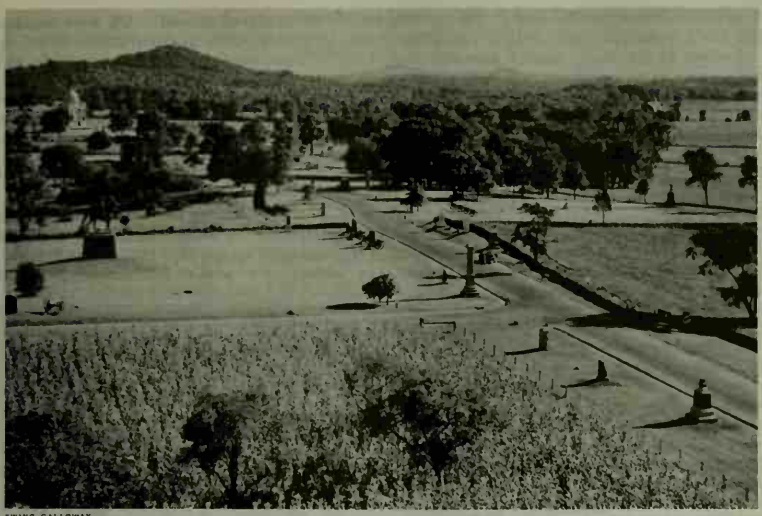
Throughout the period there was a trend toward more popular government. A new constitution in 1838 lessened the powers of the governor, increased the number of elective officers and shortened the tenure of office. In the political controversy which led up to the Civil War, Pennsylvania generally held to a moderate course, helping to elect James Buchanan of Pennsylvania to the presidency in 1856. However, the antislavery movement found much support from the Quakers and other humanitarian groups. This and the growth of the protectionist movement drew Pennsylvania toward the newly formed Republican party. In 1860 Pennsylvania elected the Republican Andrew G. Curtin as governor and gave Lincoln a majority for the presidency.

The Civil War.—As the crisis of Southern secession developed early in 1861, the state legislature pledged support to the Union, and Governor Curtin organized the state's resources in men and money. Pennsylvania supplied 323,629 soldiers to the army, as well as 14,307 sailors and marines. Industrial development was spurred by the need for munitions and supplies. During the war Pennsylvania suffered several Confederate invasions, and the turning point of the war came on Pennsylvania soil when Gen. Robert E. Lee's march into the Cumberland valley was halted at the battle of Gettysburg (July 1–3, 1863). Nearly one-third of the Union troops in that battle were Pennsylvanians. (*See* also AMERICAN CIVIL WAR; GETTYSBURG.)

After the Civil War.—Politically the state was dominated after the Civil War by a remarkable dynasty of "bosses," founded by Simon Cameron and continued by his son James Donald Cameron and by Matthew Stanley Quay and Boies Penrose until the latter's death in 1921. Under their astute management the Republican party generally ruled Pennsylvania, although reform movements occasionally interrupted their control, as when the Democrat Robert E. Pattison was elected governor in 1882 and 1890. During and after the Civil War there was tremendous expansion in the iron and steel industry, in coal mining and other industries, which transformed Pennsylvania from a predominantly agricultural state to an industrial giant. The demand for labour in the growing industrial economy brought a new wave of immigration from 1865 to 1914, and Poles, Italians, Czechs, Hungarians, Russians and others supplemented the earlier population groups. As the state grew industrially a labour movement developed and gave rise to the American Federation of Labor and the Congress of Industrial Organizations, both of which began in Pennsylvania.

Progress was made in extending the services of government. Insurance and banking departments were created in 1873 and 1891 as regulatory agencies. During the administration of Gov. Samuel W. Pennypacker (1903–07) a number of new departments were created, including forestry, health and highways, and a state police force was organized. In 1915 a department of labour and industry was established. Under Gov. William C. Sproul (1919–23) the public-school system was reorganized, an extensive program of highway building was undertaken and a department of welfare was created.

After the death of Penrose, the progressives in the Republican party gained more influence; Gifford Pinchot was elected governor



EWING GALLOWAY

GENERAL VIEW OF THE CIVIL WAR BATTLEFIELD AT GETTYSBURG

The Union battle line extended along the road from the lower right to the Round Tops in the left background, part of Cemetery ridge. The equestrian statue at left is of Union Gen. George Meade

in 1922 and 1930. During his first term (1923–27) the administrative code was enacted to consolidate departments and centralize control, thus increasing the governor's power. This was amended and made still more complete under the intervening conservative Gov. John S. Fisher (1927–31). The division in the Republican party and the coming of the New Deal brought victory to the Democrats in 1934 for the third time since the Civil War, and they elected George H. Earle as governor and one United States senator. The Republicans regained the governorship in 1938 by electing Arthur H. James, and then elected three governors in succession, Edward Martin, James H. Duff and John S. Fine. The Democratic party, however, did not revert to its former weak position; it elected George M. Leader governor in 1954 and David L. Lawrence in 1958. The Republicans returned to power in 1962, electing William W. Scranton to the governorship.

During the depression the state undertook a program of building construction at health, penal, military and educational institutions through the General State authority, approved in 1937. The first section of the Pennsylvania turnpike from Carlisle to Pittsburgh was begun in 1938. At the close of World War II the state also undertook extensive highways and public works construction, and notable progress was made in a conservation program which involved clearing rivers of silt and pollution, reforestation and soil conservation.

GOVERNMENT

Pennsylvania is governed under its fourth state constitution, adopted in 1873 and amended frequently after 1901. Amendments must be approved by a majority of each house in two successive legislatures and then ratified by a majority of a popular vote.

Executive.—The governor, lieutenant governor, auditor general and state treasurer are elected for four years and are ineligible for a second consecutive term. The secretary of internal affairs is also elected for four years but without any limitation on succession. The governor has extensive powers, appointing, subject to the advice and consent of two-thirds of the state senate, the heads of all departments except those who are elected, the members of all independent administrative boards and commissions and—with few exceptions—the members of all departmental boards and commissions. He fills vacancies in various offices which occur when the senate is not in session. His power of veto extends to items in appropriation bills; it may be overridden by a two-thirds vote in each house. His power of pardon is exercised only on the recommendation of three members of a board of pardons consisting of the lieutenant governor, secretary of the commonwealth, attorney general and secretary of internal affairs. In the event of the governor's death, resignation, conviction on impeachment or other disability, the lieutenant governor succeeds him.

A law known as the administrative code, adopted in 1923 and amended in 1927 and later, consolidated the administrative agencies of the state into 19 departments: state, justice, auditor general, treasury, public instruction, internal affairs, military affairs, agriculture, forests and waters, labour and industry, health, highways, public welfare, banking, insurance, mines, property and supplies, revenue and commerce. Important independent administrative commissions include game, fish, public utility, milk control and historical and museum; and similar boards include liquor control, parole and tax equalization. The governor and six department heads whom he designates constitute the executive board which standardizes employment in the various departments and approves the establishment or discontinuance of bureaus or other divisions in the departments. Through the budget bureau, authorized in 1929, and the office of administration, established in 1955, the governor exercises control of expenditures, personnel and policies in all but the three elective departments.

Legislative.—The legislative branch of the government is officially called the general assembly. It consists of a senate of 50 members elected for four years and a house of representatives with members elected for two years; legislation reducing the number of house seats from 210 to 209, reapportioned according to population (1960 census), was passed in 1963. The lieutenant governor presides over the senate but has no vote on the final passage of legislation. The senate has the right of confirming or rejecting appointments made by the governor and sits as a court of impeachment. The house originates appropriation bills and impeachment proceedings. The general assembly may not pass any local or special bills on a wide range of subjects but especially with regard to the affairs of counties, cities, townships, boroughs and school districts. It meets annually on the first Tuesday of January, but the sessions in even-numbered years are limited to fiscal matters. The governor may call it into special session, in which case legislation is limited to the subjects specified in his proclamation.

Judicial.—The supreme court dates from 1705, with the number of justices varying from three to five until the constitution of 1873 fixed it at seven. They are elected for terms of 21 years by the voters of the state at large; minority representation is secured by the provision that each elector shall vote for one less than the number of justices to be chosen at each election. The work of the supreme court had increased to such an extent by 1895 that the general assembly passed an act creating the superior court, consisting of seven judges elected for ten years and eligible for re-election. The supreme court handles all appealed cases involving more than $2,500 or involving felonious homicide, and is the court of last resort. The superior court handles all other appealed cases. Below the appellate courts there are courts of common pleas, courts of quarter sessions and oyer and terminer and or-

phans' courts which function in 59 judicial districts, usually corresponding to counties. Philadelphia has a municipal court, and Allegheny county a county court. Justices of the peace, magistrates and aldermen, elected in townships, city wards and boroughs, have jurisdiction over lesser crimes and disputes.

Local Government.—Counties, townships, cities, boroughs and other civil subdivisions in Pennsylvania derive their powers of self-government from the state, and the general assembly has enacted codes for each type of subdivision. Counties have been divided into eight classes on the basis of population, and cities into four classes. Under a constitutional amendment of 1922, the general assembly granted cities the right to frame and adopt their own charters, as was done by Philadelphia in 1951–52. The council-manager form of government was restricted to boroughs and townships until an enabling act passed in 1957 permitted cities to adopt the plan; Bradford and Titusville were the first to do so, in 1962.

Pennsylvania has 67 counties including Philadelphia (*q.v.*) where the functions of county government are performed by the city. The constitution provides for the election of various county officers, including a board of three county commissioners which acts as the chief administrative agency. The 51 cities are each governed by a mayor and city council, but in the third-class cities the mayor is a member of council and he and the other members direct various departments. The 938 boroughs are governed by a burgess and borough council, and there is also one town, Bloomsburg, where the president of the council performs most of the functions of the burgess. Townships are divided into two classes. The 63 first-class townships are populous suburban areas and are governed by township commissioners. The second-class townships, mainly in rural areas, are governed by township supervisors whose authority is relatively limited.

Finance.—The chief sources of state revenue are a selective sales and use tax and taxes on motor vehicles, corporations, motor fuels, alcoholic beverages, tobacco and inheritance. In 1933 the state assumed control of the sale of alcoholic beverages, setting up a system of state stores for the sale of wine and liquor. From this source it derived an income of more than $80,000,000 annually in the 1960s. More than half the state's income was spent on education and highways. The state net debt more than trebled during the post World War II period. It was greatly increased in 1949 and 1957 as the result of state-wide elections authorizing the payment of bonuses to veterans of World War II and the Korean War.

POPULATION

The population of Pennsylvania in 1790 was 434,373; in 1830 it was 1,348,233; in 1870, 3,521,951; in 1910, 7,665,111; in 1950, 10,498,012; and in 1960, 11,319,366. This last figure represented an increase of 7.8% over 1950. The population per square mile in 1960 was 249.7, as compared with 231.6 in 1950 and with 49.6 for the U.S. in 1960.

The urban area, defined as including all incorporated places of 2,500 or more, all townships having a total population of 10,000 and a density of 1,000 or more persons per square mile, the thickly settled suburban area or "urban fringe" adjacent to cities of 50,000 or more and unincorporated places of 2,500 or more outside this fringe, had a population in 1960 of 8,102,051 or 71.6% of the state total. In 1950 the comparable figures were 7,403,036 and 70.5%. In 1960 the state's 12 standard metropolitan statistical areas had a population of 8,813,274 or 77.9% of the state total; enlargement of SMSAs in 1963 increased population in these areas by about 111,000. Occupied dwelling units in 1960 numbered 3,350,839; average population per household was 3.3.

The population of the state was distributed by colour and nativity in 1960 as follows: 87.1% native white; 5.2% foreign-born white; and 7.6% nonwhite, practically all Negro. Of the foreign-born population in 1960, 20.4% were born in Italy, 12.0% in Poland, and 11.1% in the United Kingdom. There were 94.8 males per 100 females in 1960, compared with 97.0 in 1950. Ten per cent of the population was 65 years old or over; 38.9% of the population 14 years old and over was in the labour force.

Of the total number of employed persons, 2.6% were engaged in agriculture, 1.6% in mining, 4.2% in construction, 38.7% in manufacturing, 7.5% in transportation, 18.7% in wholesale and retail trade and 13.5% in service activities.

In spite of the great volume of immigration from southern and eastern Europe which came mainly to the industrial centres in the latter part of the 19th century, the original population pattern of the state is still noticeable in customs, architecture and speech. This is especially true in Lancaster, Berks, Lebanon, Lehigh and neighbouring counties where persons of German descent, the Pennsylvania Dutch, predominate. Of these the most distinctive are the "plain people," members of the Mennonite, Amish, Dunkard and other small sects, who make up less than 10% of the Pennsylvania Dutch. The "plain people" tend to retain more of the old

speech, customs and dress than the other Pennsylvania Dutch. The industrious diligence of the Pennsylvania Dutch has kept their region as a prosperous farming country for two centuries, and they are noted for their well-kept fields and large barns, often decorated with geometric designs called "hex" signs. Authorities differ on whether these are talismans for protective purposes or merely for decoration. The Pennsylvania Dutch love of colour and decoration is expressed in their folk art.

EDUCATION

Public-School System.—Pennsylvania's system of free public education began with the Free Public School act of 1834 which created local school districts, permitted the levy of taxes for the support of free elementary schools and provided state aid to districts accepting the act. Earlier laws had provided schooling for children 5 to 12 years old whose parents were unable to pay for it, but these were called pauper education acts and parents were reluctant to educate their children on such terms. Despite some early opposition, the public-school system gradually expanded and the state constitution of 1873 definitely provided for the education of all children above the age of six years and for a state superintendent of public instruction. High schools were established in Philadelphia and Pittsburgh in 1836 and 1849 and were authorized in every district of the state in 1895.

In 1834 the minimum school term was three months; by 1899 it had been lengthened to seven months; and it was finally extended to a minimum of 180 days of school. In 1895 the first compulsory school attendance law required all children 8 to 13 years of age to attend school 16 weeks a year, with certain exemptions provided by law. This was subsequently extended to make attendance compulsory for all children between the ages of 8 and 16 throughout the school year. About 1,750,000 children enrolled annually in the public schools and about 460,000 in private and parochial

schools. Even in 1834 the state made substantial contributions to the support of the schools. In 1921 the state appropriations were made contingent on the maintenance of certain minimum standards as to courses and teachers' salaries and qualifications. By the second half of the 20th century the annual state appropriations amounted to almost $200,000,000.

Higher Education.—After 1854 the need for trained teachers led to the establishment of normal schools under private auspices. These schools received a gradually increasing amount of state aid, and in 1911 the state was authorized to purchase them. In 1926 they were reorganized as state teachers' colleges at Bloomsburg (originally founded in 1839), California (1852), Cheyney (1837), Clarion (1866), East Stroudsburg (1893), Edinboro (1857), Indiana (1871), Kutztown (1866), Lock Haven (1877), Mansfield (1858), Millersville (1854), Shippensburg (1871), Slippery Rock (1889), and West Chester (1869). They offer four-year courses leading to the degree of bachelor of science in education and became state colleges in 1959.

Pennsylvania State.—Pennsylvania State university at University Park, a land-grant institution, receives almost its entire financial support from public revenue. Originally chartered in 1855 as Farmers' high school, it first gave instruction on the college level in 1859. The name was changed to the Agricultural College of Pennsylvania in 1862, to Pennsylvania State college in 1874 and to Pennsylvania State university in 1953.

The university includes colleges of liberal arts, agriculture, business administration, chemistry and physics, education, engineering and architecture, home economics, physical education and athletics, and mineral industries and schools of journalism and forestry. Fourteen two-year branch campuses are located throughout the state. A department of nuclear engineering was set up in 1958, and the Research Reactor building on the University Park campus contains an atomic reactor used in various research projects. Also in 1958 the Groth institute of crystallography and a centre for continuing liberal education were established. The university owns a student-operated FM station.

The University of Pennsylvania.—The University of Pennsylvania, Philadelphia, was founded in 1740 as a charity school. Largely through the efforts of Benjamin Franklin and other leading citizens of Philadelphia, it was transformed in 1753 into an academy, with Franklin as president of the first board of trustees. Two years later it was chartered as the College and Academy of Philadelphia. With the foundation in 1765 of the first medical school in North America the institution became in fact a university, but it was not so called until 1779 when it was, for a time, state supported. Following the passage of an act of the state legislature in 1791 it became a privately endowed and controlled institution, although it receives some state aid.

The divisions of the university include the colleges of arts and sciences, liberal arts for women and general studies, schools of education, engineering, law, dentistry, medicine, veterinary medicine, social work, allied medical professions, nursing and fine arts and the Wharton school of finance and commerce. The Wistar Institute of Anatomy, the first anatomical institute in America devoted entirely to research, was founded in 1892. Also part of the university are the Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis, affiliated with the university in 1910; the William T. Carter foundation of Child Helping; the Institute of Local and State Government; the Albert M. Greenfield Center for Human Relations; and the Psychological Laboratory and Clinic, founded in 1887, the oldest such institution in the United States. Among its activities the university offers through the Institute for Humanistic Studies a special program for corporation executives. Teaching and research programs in radio, television and allied fields are given by the Annenberg school of communications. The university participates with Princeton in the operation of a high-energy nuclear research centre sponsored by the U.S. Atomic Energy commission.

Other Universities and Colleges.—Pennsylvania is especially rich in institutions of higher learning, many of them dating back to the 18th century. Dickinson college at Carlisle (Methodist) was founded in 1773; Franklin and Marshall college, Lancaster (United Church of Christ), the University of Pittsburgh (nonsectarian) and Washington and Jefferson college, Washington (nonsectarian), were all founded in 1787. Philadelphia, which first became a cultural centre in colonial times, is the seat of Temple university (1884; nonsectarian), Drexel Institute of Technology (1891; nonsectarian), LaSalle college (1863; Roman Catholic) and St. Joseph's college (1851; Roman Catholic), among others. Bryn Mawr college for women (1880; nonsectarian), Haverford college (1833; Society of Friends), Swarthmore college (1864; nonsectarian) and Villanova university (1842; Roman Catholic) are located nearby in municipalities of the same names. Other Pennsylvania universities and colleges include Allegheny college, Meadville (1815; Methodist), Bucknell university, Lewisburg (1846; nonsectarian), Duquesne university (1878; Roman Catholic) and the Carnegie Institute of Technology (1900; nonsectarian), both at Pittsburgh, College Misericordia, Dallas (1924; Roman Catholic), Gannon college, Erie (1944; Roman Catholic), Geneva college, Beaver Falls (1848; Reformed Presbyterian), Gettysburg college, Gettysburg (1832; Lutheran), Grove City college, Grove City (1876; Presbyterian), Lafayette college, Easton

(1826; Presbyterian), Lehigh university, Bethlehem (1865; nonsectarian), the University of Scranton (1888; Roman Catholic) and Marywood college (1915; Roman Catholic), both at Scranton, Westminster college, New Wilmington (1852; Presbyterian) and Wilkes college, Wilkes-Barre (1933; nonsectarian). *See* also PHILADELPHIA.

HEALTH AND WELFARE

Care of the needy was recognized as a public responsibility even under the duke of York and again in the Great Law of 1682. For a long period poor relief was administered by poor boards or overseers of the poor in a complex system which had no uniform pattern, and there were county homes or almshouses for institutional relief in most of the counties. In 1937 a uniform system was established. The county homes and similar institutions were placed under county institution districts and a state department of assistance was created to function through county boards of assistance in administering old-age assistance, general assistance to the unemployed, aid for dependent children and the disabled, blind pensions, unemployment counseling, school medical assistance, burial assistance and foster homes. In the 1960s almost half the money expended for these programs came from the federal government. The department of assistance was merged with the department of welfare in 1958 to create the department of public welfare.

The department of welfare operated 18 hospitals for mental disorders, four schools for mental defectives and ten state-owned general hospitals. The management of penal and correctional institutions was transferred to the state justice department in 1953. They include four penitentiaries, an institution for defective delinquents, an industrial home for women, an industrial school and two diagnostic and classification centres. A board of parole was created in 1941.

THE ECONOMY

Agriculture.—Although Pennsylvania is an industrial rather than an agricultural state, it remains important for its farm production, ranking among the first 15 states in cash receipts from farm products in the second half of the 20th century. About 50% of its area was in farms and more than half of its farm acreage was improved. The number of farms increased from 127,577 in 1850 to 224,248 in 1900 but gradually decreased thereafter as submarginal farms were abandoned and also as small farms were consolidated into larger farms. The value of all farm property in 1930 was $1,535,484,000. This decreased by about one-third during the depression and World War II years, but the earlier position had been substantially regained by the 1960s.

Farming in Pennsylvania began as general farming with emphasis on grain growing. About 1790 livestock farming began to assume greater importance, but there was also diversification into fruit growing and truck farming. About 1900 dairy farming to produce milk became the most important farm enterprise, and milk, dairy products, poultry, eggs and other livestock products came to exceed by far all other agricultural products in value. Dairy farming predominates in the northern counties, where a shorter growing season favours pastures and the growing of hay, but the greatest number of cattle are in the south and west. More than 6,000,000,000 lb. of milk are produced annually. The number of sheep declined precipitously after 1900, but swine increased in both numbers and value. Chicken raising is an important source of farm income.

Usually all the rough, and most of the concentrated, food for stock is raised on the farms. Corn is the leading crop in value. Others include tame hay, wheat, oats, potatoes, barley, rye, buckwheat and commercial truck crops. Pennsylvania ranks high among the states in buckwheat production. Most of the buckwheat, barley and oats are grown in the northern and western counties, while corn, wheat and rye are raised more extensively in the northeast. Tobacco is raised chiefly in Lancaster county; Pennsylvania leaf is especially valued as a cigar filler and wrapper. Adams, Franklin and York counties in the south central part of the state and Erie county in the northwest are the principal fruit-growing sections. Adams county leads in the production of apples. Peaches are grown in most of the southern counties and grapes are raised mainly in the lakeshore section of Erie county.

Important farm groups have formed state associations for the study of improved methods and the advancement of their interests, beginning with the dairy farmers in 1874. A state board of agriculture was created in 1876 and this became a department in 1895. Agricultural education has been developed extensively in the schools, and the extension services of the college of agriculture of Pennsylvania State university have helped to introduce scientific methods. Soil conservation districts have been set up by many counties in co-operation with the state department of agriculture to control and prevent erosion and otherwise maintain soil resources.

Industry.—Pennsylvania consistently ranks second to New York in the value of its manufactures, which increased from about $2,800,000,000 in 1914 to more than $7,000,000,000 in 1923, declined to around $3,000,000,000 during the depression of the 1930s but rose to much more than $25,000,000,000 by the mid-1950s. Reflecting the same economic trends, the number of plants fell from around 27,500 in 1914 to about 12,000 in 1933 and then rose to about 20,000 in the 1960s, when there were about a third more employees than in 1914. These figures reflect a trend toward larger plants.

The development of manufacturing resulted largely from abundance of fuel, the facilities for shipment through the port of Philadelphia, the availability of the ores of the Lake Superior region and the development of transportation, first by canal and later

EWING GALLOWAY

STEEL MILL ON THE ALLEGHENY RIVER AT ETNA, NEAR PITTSBURGH

by railroad. By far the most important industry is the production of iron and steel. The first ironworks in Pennsylvania was a bloomery forge, a hearth-type furnace loaded with alternate layers of charcoal and iron ore to produce wrought iron, erected by Thomas Rutter in Berks county in 1716. Charcoal iron furnaces were numerous in eastern Pennsylvania after that time, and the industry continued to prosper and expand there when anthracite took the place of charcoal. With the increase in the use of bituminous coal and of coke made from it, and with the development of the steel industry, western Pennsylvania became the iron and steel manufacturing centre and the Pittsburgh district in particular received a new impetus from the introduction of iron ore from the Lake Superior region.

Pennsylvania's industries are remarkable for their diversity and balance. Although metals are by far the most important, it is virtually impossible to mention a single manufactured product which is not made somewhere in the state. Such diversification has tended to diminish the effects of the decline in coal mining and similar but more temporary slumps in various industries. In the 1960s the leading manufactures were primary metal products, fabricated metal products, electrical and other machinery,

food and kindred products, textiles, apparel and related products, paper, pulp and products, printing and publishing, chemicals, stone, clay and glass products, transportation equipment and petroleum and coal products.

Philadelphia is the great manufacturing centre of the state and one of the most important in the nation. It is surrounded by an area of highly diversified industry. In the 1960s, for example, there were within the city more than 4,000 factories which had a product valued at more than $5,000,000,000, or about one-quarter of the total produced in the state. Despite the development of steel mills in other parts of the state and nation, Pittsburgh remained the centre of the iron and steel industry. After Philadelphia and Pittsburgh, the more important manufacturing cities are Erie, Scranton, Reading, Allentown, Bethlehem, Chester, Wilkes-Barre, New Castle, Lancaster, Harrisburg, York, Altoona and Williamsport (*qq.v.*).

Mining.—*Coal.*—A large part of Pennsylvania's mineral output is represented by coal. With the exception of small areas in Colorado and New Mexico, Pennsylvania contains the only anthracite deposits in the United States. They are found within an area of less than 500 sq.mi. in the northeastern part of the state, chiefly in Lackawanna, Luzerne, Carbon, Schuylkill and Northumberland counties. In addition, Pennsylvania has extensive bituminous coal measures, and most of the coal obtained from these is of high quality. They form the northern extremity of the great Appalachian coal field and underlie an area of 15,000 sq.mi. or more in the west of the state. The Pittsburgh district, comprising the counties of Allegheny, Washington, Fayette and Westmoreland, is exceptionally productive. The coal in Allegheny and Washington counties is noted for its gas-producing qualities, while the famous Connellsville coking coal is obtained in Fayette and Westmoreland counties. The output of coal in Pennsylvania rose steadily from 1880, when 28,650,000 tons of anthracite and 18,425,000 tons of bituminous were mined, to World War I, when the peak figures were 99,612,000 tons of anthracite in 1917 and 178,551,000 tons of bituminous in 1918. Thirty years later, in 1948, the respective tonnages had fallen to 57,140,000 and 132,550,000, and by the 1960s had declined to about 17,000,000 and 65,000,000. This decline reflected technological changes in industry and transportation and a shift from coal to natural gas and oil for home heating. It caused much unemployment in the coal regions, which have sought to develop new industries. The state makes loans to aid local authorities in attracting new plants to these depressed areas, and research is being conducted to find new ways of utilizing coal. Vast coal reserves remain underground. In the early 1960s recoverable reserves, assuming 50% recovery, were estimated at more than 35,000,000,000 tons.

Petroleum.—Extending from the southwest corner of the state is the Pennsylvania section of the Appalachian oil field which, with a small section in New York, furnished nearly all of the country's supply of petroleum for several years after the discovery of its value for illuminating purposes. The first petroleum well was drilled by Edwin L. Drake near Titusville in 1859, and oil wells were developed rapidly in the Oil creek valley and up the Allegheny river from Franklin to Tidioute. The state's output of petroleum reached its peak in 1891 with a production of 31,424,206 bbl. Thereafter the yield declined as the older wells were exhausted and few new wells were developed; in the 1960s production was only about 5,000,000 to 7,000,000 bbl. a year. While the quantity produced has become relatively small, however, the physical and chemical characteristics of Pennsylvania oil give it special value as a base for lubricants.

Natural Gas.—Much natural gas was found and wasted in the early years of oil production, but later it was utilized as a fuel and an illuminant. The peak recorded natural gas production, 138,000,000,000 cu.ft., came in 1906 but it fell to 61,000,000,000 cu.ft. in 1932. This figure was subsequently raised by the discovery of the Leidy gas field in Clinton county.

Iron.—Deposits of various kinds of iron ore were found in the southeastern, eastern, central and some of the western counties, and from the middle of the 18th century until near the close of the 19th Pennsylvania ranked high among the states in production of iron ore. As late as 1880 it was first with 1,951,496 long tons. After the first successful experiments in making pig iron with coke made from bituminous coal, the state's iron foundries rapidly moved westward into the bituminous coal area and away from the early producing centres. The shipment of iron ore from the Lake Superior region, beginning about 1853, caused a further decline of iron mining within the state, since Lake Superior ore could be shipped to the Pittsburgh region at less cost than ore could be shipped from mines within the state. In 1932 the ore mined amounted to only 103,000 long tons, but it increased somewhat thereafter. Most of this ore comes from one mine, the famous Cornwall ore banks, worked continuously since 1740.

Miscellaneous Minerals.—Pennsylvania has extensive areas of limestone rock suitable for making cement, and enormous quantities of it are used in this industry in Northampton and Lehigh counties. In Lehigh county the first successful portland cement plant in the United States was erected in 1870, and thereafter Pennsylvania continued to lead all states in annual cement output. Limestone and dolomites suitable for building purposes are obtained chiefly in Montgomery, Chester and Lancaster counties. Until increased facilities of transport brought more desirable stones into competition they were used extensively in Philadelphia. There are limestone quarries in nearly two-thirds of the counties and great quantities of this stone are used for flux in iron furnaces, for making quicklime, for railway ballast and in road building. Northampton, Lehigh and York counties contain the most productive slate quarries in the U.S. Northampton and Lehigh slate is the only kind in the United States used for school blackboards. There is an extensive area in the southeastern part of the state containing shale clay of a superior quality for making common brick. Kaolin abounds in Chester and Delaware counties, and fire clay in several of the western counties. The state leads all others in the value of its clay and clay products. Glass sand is abundant in both the eastern and western regions, and for many years Pennsylvania has ranked among the leading states in the manufacture of glass. In Chester county, also, is one of the most productive deposits of feldspar, second only to those of Maine.

Trade and Finance.—From colonial days when Philadelphia merchants developed a prosperous commerce with other colonies and with Europe, trade has been an important element in the state's economy. The internal improvements of the 19th century opened channels of trade with the west, and Pittsburgh grew to economic importance as the commercial gateway to the Ohio valley. In the 1960s there were more than 15,000 wholesale trade establishments and 120,000 retail establishments in the state.

Pennsylvania has one port of entry on the Atlantic coast, one on the Ohio river and one on the Great Lakes. Philadelphia, the Atlantic port, exports chiefly coal, grain and flour and imports chiefly petroleum, iron ore, sugar, drugs and chemicals, manufactured iron, hemp, jute and flax. It has long ranked second among the ports of the United States in the tonnage of its foreign commerce, surpassed only by New York city. Pittsburgh has ranked high among U.S. interior ports. Erie has been an important port in the Great Lakes trade and received its first ocean-going vessel through the St. Lawrence seaway in May 1959.

The thriving commerce of colonial Philadelphia built up surplus wealth for investment and gave it an early lead as a financial centre. The first fire insurance company to be chartered in America was the Philadelphia Contributionship, founded in 1752, and the first life insurance company was formed in 1759. In 1780, 90 Philadelphians formed a bank to finance the Revolutionary army, and this bank was succeeded by the Bank of North America, chartered by congress in 1781 and by Pennsylvania in 1782, the first bank to be chartered in America. The first and second Banks of the United States were also located in Philadelphia, and many other banking institutions developed there and elsewhere in Pennsylvania. Although New York city became the leading financial centre after the Civil War, Pennsylvania remained important in this field with many insurance companies and with banks and savings and loan associations in all important centres of population. A decline in the number of banks reflected the growth of branch banking.

Transportation and Communication.—Transportation was an essential factor in Pennsylvania's development. Since the mountain ranges made east-west travel difficult, it was necessary to overcome these difficulties by roads, canals and railways. After the early roads, turnpikes and canals (see *History*, above), a network of railways began to develop between 1830 and 1860. The Philadelphia & Reading railway, begun in 1835, and the Lehigh Valley railroad, chartered in 1846, gradually extended their lines to link the coal regions with New York state. The Pennsylvania railroad, chartered in 1846, opened its line from Harrisburg to Pittsburgh in 1852, using the tracks of the state's Allegheny portage railroad until its own mountain division was finished. Later, it purchased the main line of the state works and thus had a complete rail line from Philadelphia to Pittsburgh, with the state's Columbia railroad. It then extended its lines rapidly to become one of the nation's most important railroads. With these and other railways the state had a virtually complete network of rail transportation by the time of the Civil War. Although some additions were made later, the basic pattern was already established. The railway mileage, 8,453 in 1890, increased to 11,693 in 1915. This had decreased somewhat by the early 1960s, but Pennsylvania still had more than 9,000 mi. of track.

In 1911 the state began an extensive program of highway construction. After 1918 funds were provided by bond issues, drivers' licence fees and a gasoline tax. By the 1960s the state highway system included more than 40,000 mi. of improved roads, while county, township, city, and borough highways totaled over 60,000 mi. In 1938 the Pennsylvania turnpike was begun as a toll road penetrating the Allegheny mountains through seven tunnels to connect eastern and western Pennsylvania. This four-lane limited-access highway was opened from Carlisle, near Harrisburg, to Pittsburgh in 1940, and later extended from the Ohio border to the Delaware river, where it was connected with the New Jersey turnpike in 1956. In 1957 a northeastern extension to Clarks Summit was completed, and the entire system totaled 470 mi.

The communication of ideas was also important to Pennsylvania's progress. The first newspaper was established in Philadelphia in 1719, the fourth in the American colonies. By 1775, 9 newspapers were published in Pennsylvania and by 1810 there were 73. These grew to more than 400 with a total circulation of over 8,000,000. Other means of communication also developed early.

The first commercial telegraph line in the United States was opened from Philadelphia to Lancaster in 1846 and the telephone was introduced in the 1880s. The first commercial radio broadcasting station in the world was KDKA, Pittsburgh, which began a regular daily schedule on Nov. 2, 1920. Pennsylvania has almost 100 telephone companies and more than 5,000,000 telephones are in use. There are more than 200 radio stations and more than 20 television stations.

PENNSYLVANIA, UNIVERSITY OF, a U.S. institution of higher learning, founded in 1740 at Philadelphia, Pa. *(see* PENNSYLVANIA: *Education*).

PENNY, a British coin (German *pfennig*), equal in value to one-twelfth of a shilling *(q.v.)*, denoted after a numeral by *d.* (from Lat. *denarius*). The term is also used colloquially in the United States to denote a cent, the hundredth part of a dollar.

Whatever earlier currency the name and denomination may have had, it was not until the reign of Offa (757–796) that English coinage was formally based on a silver penny showing the king's name on the obverse. Offa's penny weighed 22½ gr. and 240 pennies weighed one Saxon pound (or Tower pound, as it was afterward called), hence the term pennyweight (dwt.). In 1257 Henry III struck experimentally a gold penny of the value of 20 silver pence. During the reign of his successor, Edward I, halfpence and farthings (four to a penny) became a regular part of the coinage, the penny having been cut for trade purposes into halves, quarters, and perhaps even thirds. The silver penny remained the general coinage of England until the introduction of the gold florin by Edward III in 1344. The weight and value of the silver penny declined from 1300 onward. Whereas in 1066 it weighed 22½ gr., in 1300 it weighed 22 gr. and by 1601 it weighed only 7¾ gr.

Silver pence were struck for general circulation until the reign of George II; since then they have been coined only as part of the royal alms on Maundy Thursday. Copper halfpence were first issued by Charles II, but it was not until 1797 that copper pence were struck, weighing 1 oz. avoirdupois, together with copper twopences weighing 2 oz.: both series were found cumbersome and were soon discontinued. In 1860 bronze was substituted for copper, the alloy containing 95 parts of copper, four of tin, and one of zinc. The weight was also reduced, 1 lb. of bronze making 48 pennies, as against 24 of the earlier copper pennies. The figure of Britannia first appeared on the copper coins of Charles II.

ROCHE

AMERICAN PENNYROYAL (HEDEOMA PULEGIOIDES)

PENNYROYAL, an aromatic herb formerly much used in medicine, the name being a corruption of the old herbalist's name "Pulioll-royall," *Pulegium regium*. It is a member of the mint genus, and has been known to botanists since the time of Linnaeus as *Mentha pulegium*. It is a perennial herb with a slender branched stem, square in section, up to a foot in length, and rooting at the lower nodes, small opposite stalked oval leaves about half an inch long, and dense clusters of small reddish-purple

flowers in the leaf axils, forming almost globular whorls. It grows in damp gravelly places, especially near pools, on heaths and commons. It has a strong smell somewhat like that of spearmint, due to a volatile oil which is readily obtained by distillation with water, and is known in England as *Oleum pulegii*. The specific name recalls its supposed property of driving away fleas (*pulices*). Like the other mints it has carminative and stimulant properties.

The similar American pennyroyal (*Hedeoma pulegioides*), also belonging to the mint family (Labiatae), occurs in dry fields from Cape Breton Island to Ontario and North Dakota, southward to Florida and Arkansas.

PENOLOGY (or Correction), that part or division of criminology concerned with the philosophy and practice of prison administration and the treatment of prisoners. *See* Crime; Criminology; Juvenile Delinquency; Prison.

PENRITH, a market town and urban district of Cumberland, Eng., lies 18 mi. SSE of Carlisle on the trunk (A6) road to Scotland and at the foot of Penrith Beacon (937 ft. [286 m.]). Pop. (1961) 10,931. In the town are the ruins of Penrith Castle, built in the 14th century as a defense against raids from the Scots and dismantled during the Civil War in the 17th century. The parish church of St. Andrew is of Norman foundation with a 14th-century tower and a list of vicars complete from 1223. In the churchyard are the "Giant's Grave" (ancient hogback stones and cross shafts) and the "Giant's Thumb" (the remnant of a 10th-century rose cross). A 14th-century grammar school was refounded by Elizabeth I in 1564. Buildings of historical interest include the Gloucester Arms, associated with Richard III; Hutton Hall (1480), incorporating an old peel tower; Roger Bertram's house, dated 1563; and Gerard Lowther's house (1584), now the Two Lions Hotel. Samuel Plimsoll, the social reformer, and John Loudon McAdam, the inventor, were temporary residents of the town. Long-case or "grandfather" clocks, manufactured by the Porthouse family, made Penrith famous during the 18th century.

The ruins of Brougham Castle, with a 12th-century keep, stand on the site of the Roman fort of Brocavum, 1½ mi. (2½ km.) SE of Penrith, and 5 mi. (8 km.) N are the remains of Voreda, a Roman military settlement. Edenhall village, 3½ mi. (5½ km.) NE, recalls the 13th-century Syrian enameled glass goblet, known as the "Luck of Eden Hall," which belonged to the Musgrave family and is now in the Victoria and Albert Museum in London. Penrith Beacon, with golf course adjoining, is a fine viewpoint for the mountains of the Lake District (*q.v.*).

Penrith is a rail and road junction. The nearest air services operate from Carlisle and in the early 1960s provision was made for a helicopter landing site.

Penrith depends mainly upon agriculture, particularly livestock rearing, and weekly cattle sales. It is also a tourist centre by virtue of its position as the northern gateway to the Lake District, being only five miles from Ullswater. (C. H. Hu.)

PENROSE, RICHARD ALEXANDER FULLERTON, JR. (1863–1931), U.S. economic geologist, who left a large fortune to scientific societies, was born in Philadelphia, Pa., on Dec. 17, 1863. He was graduated from Harvard University (A.B., 1884; Ph.D., 1886), where he acquired a broad view of science and a practical one of geology. After writing his thesis on phosphates, he managed mines for the Anglo-Canadian Phosphate Company (1886–88) and later surveyed mineral deposits for the states of Texas (1888–89) and Arkansas (1889–92).

In 1892 he became professor of economic geography at the University of Chicago, and was full professor, 1895–1911. In 1895 Penrose was a founder of the Commonwealth Mining and Milling Company at Pearce, Ariz., which produced gold; and in 1903 he founded, with his father and brother Spencer, the Utah Copper Company at Bingham, Utah. The property proved to be in the largest deposit of porphyry copper in the world and became the largest single producing area in the United States.

A founder of the Society of Economic Geologists in 1920, he was its first president. He established the Penrose gold medal for economic geology and a similar medal for outstanding work in any aspect of geology, to be awarded by the Geological Society of America. He was president of that society in 1930–31. He never married and at his death on July 31, 1931, the bulk of his estate of about $10,000,000 was left to the Geological Society of America and the American Philosophical Society.

PENRY, JOHN (1563–1593), an Elizabethan Puritan, author of some of the most famous early Puritan treatises, was born in Brecknockshire and in 1580 proceeded to Peterhouse, Cambridge, where he graduated in 1584. Although he came from a farm in the uplands of Wales, he seems to have been in easy circumstances. An anonymous pamphleteer maintained that when he went to Cambridge he was "as arrant a Papist as ever came out of Wales," but this is probably without foundation. At Cambridge, however, he became convinced of his own sinfulness. He thereupon adopted a Puritan mode of life and began to advocate Presbyterianism as the ideal form of church government. After graduating he left Cambridge, presumably returning to Wales, but in 1586 he was at Oxford, where he proceeded to the M.A. degree. He did not take holy orders.

Penry's primary concern after leaving the university was with the religious condition of Wales. On this he wrote three treatises which are known by their short titles, the *Aequity* (1587), the *Exhortation* (1588), and the *Supplication* (1588). They are violent and antiepiscopal in tone. He advocated the preaching of the gospel in Welsh, the return to Wales of Welsh-speaking incumbents of English livings, and, if necessary, the use of lay evangelists. The first treatise led to his being summoned before the Court of High Commission and to his imprisonment for a month. Presumably on this account, his subsequent treatises were printed on a secret press. From the same press came the celebrated Martin Marprelate tracts (*see* Marprelate Controversy), which attacked the bishops with scurrility and wit. A bookbinder who turned informer accused Penry of being their author. Another suspect was his friend Job Throckmorton, member of Parliament for Warwickshire. In a letter from prison later, however, Penry denied that either he or Throckmorton even knew who Martin was, and this denial is now generally accepted. When the search for the press intensified, Penry fled in 1590 to Scotland. In the meantime he had married Eleanor Godley of Northampton.

In Scotland Penry abandoned Presbyterianism in favour of Separatism, and one of his posthumous works, *The Historie of Corah, Dathan, and Abiram* (published 1609), is a notable contribution to the literature of religious toleration. On his return in 1592 he threw in his lot with the London Separatists. At this time Richard Bancroft (*q.v.*) was actively suppressing Puritanism. Penry was arrested and was charged under the Act of Uniformity. Although that act did not carry the death penalty, he was condemned to death and executed on May 29, 1593.

Bibliography.—W. Pierce, *John Penry* (1923); A. Peel (ed.), *Notebook of John Penry, 1593* (1944); John Penry, *Three Treatises Concerning Wales,* introduction by D. Williams (1960). (Da. W.)

PENRYN, a market town, port, and municipal borough in the Falmouth and Camborne-Redruth parliamentary division of Cornwall, Eng., 2 mi. NW of Falmouth and 34 mi. (55 km.) ENE of Land's End by road. Pop. (1961) 4,451. The town lies at the head of the estuary of the Penryn River, which opens on the west coast of Carrick Roads, into which flows the Fal. It owed its development to the bishops of Exeter, within whose demesne lands it stood. These lands appear in Domesday Book under the name of Trelivel. Its first charter was granted by Bishop Bruiere in 1236. Glasney College was founded by Bishop Walter Bronescombe in 1265; it appears to have been suppressed in 1547. Bishop Walter de Stapeldon secured a market on Thursdays, a fair at the Feast of St. Thomas, and, in 1311, a three days' fair at the Feast of St. Vitalis. Mary I gave the parliamentary franchise to the burgesses in 1553. James I granted and renewed the charter of incorporation, providing markets on Wednesdays and Saturdays and fairs on May 1, July 7, and Dec. 21. The charter having been surrendered, James II by a new charter among other things confined the parliamentary franchise to members of the corporation. This proviso, however, was soon disregarded, the franchise being freely exercised by all the inhabitants paying scot and lot. From 1553 to 1832 the borough returned two members to Parliament.

An attempt to deprive it of its members, because of corrupt practices, was defeated by the House of Lords in 1827. The act of 1832 extended the franchise to Falmouth, in spite of the rivalry existing between the two boroughs. In 1885 the united borough was deprived of one of its members.

There is no parish church within the borough boundaries, but the Church of St. Gluvias, to the north, fulfills this function. Although largely restored in 1883 it retains a 15th-century tower. Penryn is the principal port for the shipment of granite which is extensively quarried in the neighbourhood, and dressed and polished at Penryn. There are also engineering works, boat repairing, and lumberyards. The harbour dries at low tide, but at high tide has 13 ft. (4 m.) of water.

PENSACOLA, a city of Florida, U.S., located in the northwestern part of the state on the northern shore of Pensacola Bay about 6 mi. (11 mi. by channel) N of the Gulf of Mexico and 50 mi. SE of Mobile, Ala.; the seat of Escambia County. The city is separated from the Gulf of Mexico by Santa Rosa Island. At the western end of the island is Ft. Pickens and across the channel to the west is Ft. Barrancas. Pensacola retains much of the atmosphere of an old Spanish city, with its Plaza Ferdinand VII, Seville Square, Spanish street names, and religious festivals. From the ochre-yellow banks of the bay the city rises gently to heights commanding views of beautiful bayous and the Escambia River, which flows into the bay on the east. Public parks and beaches give pleasure to thousands. There are two public junior colleges: Pensacola, organized in 1948, and Washington, opened in 1949. The city has a council-manager form of government in effect since 1931.

The city's trade area includes parts of Alabama, Louisiana, and Georgia. Nylon yarn, paper, wallboard, industrial chemicals, lumber, naval stores, tile, concrete, cottonseed oil, and small boats predominate as manufactured products. The deep-water port of Pensacola suffers because of its proximity to Mobile.

Pensacola Bay was discovered in 1516 by a ship's pilot, Diego Miruelo. In 1528 Pánfilo de Narváez with 242 followers made a water stop at Pensacola. In January 1540 Diego Maldonado, commander of Hernando de Soto's fleet, entered the harbour and named it Puerto d'Achusi.

Tristán de Luna in 1559 colonized the bay, which he renamed Santa María de Gálvez, but the settlement was abandoned two years later.

An expedition under Juan Enríquez Barroto and Antonio Romero rediscovered Pensacola Bay on Feb. 6, 1686, while searching for a colony planted by René Robert Cavelier, sieur de la Salle. Reports describing the friendly Panzacola Indians and the magnificent bay inspired an expedition, led by Adm. Andrés de Pez and Carlos de Sigüenza y Góngora, a noted Mexican mathematician, to explore Pensacola Bay in 1693. It was, however, renewed French interest in the area which galvanized the Spanish into action. In 1698 expeditions under Andrés de Arriola and Capt. Juan Jordán de Reina established Ft. San Carlos at the entrance of the bay.

In the brief French-Spanish War of 1719–20 Pensacola was seized by Jean Baptiste le Moyne, sieur de Bienville, almost immediately recaptured by Spain, seized again and burned by France and restored to Spain in the treaty of Feb. 17, 1720. A small garrison was maintained by Spain after 1720 and, except for a hurricane which destroyed the town in 1754, the post was undisturbed. At the end of the Seven Years' War the Floridas, including Pensacola, were transferred to England. Although the Spanish inhabitants left for Mexico and Cuba, the British swiftly reestablished the settlement and Pensacola was made the capital of West Florida.

During the American Revolution Pensacola was a haven for Tories. On May 9, 1781, it was captured by Bernardo de Gálvez, the Spanish governor at New Orleans, and Spanish possession was confirmed in the definitive treaty of peace of 1783.

During the War of 1812 the British made Pensacola a centre of operations despite Spanish protests, and in 1814 entered the harbour to take formal possession, but were repulsed by Gen. Andrew Jackson. In 1818 General Jackson captured the city from the Spanish, maintaining that they were encouraging the Seminole Indians in raids against the U.S., and in 1821 Florida as a whole was finally transferred to the U.S. In 1824 Pensacola was chartered as a city and was selected as the site of a federal navy yard. Three months before outbreak of the American Civil War, on Jan. 12, 1861, the navy yard was seized by the state government but Ft. Pickens remained under federal control and on May 8, 1862, the Confederates evacuated the city.

Railroad development after the Civil War led to extensive lumbering, which in a few years devastated the pine forests of the area. In 1872 commercial shipment of fish began and by the 1880s Pensacola seafood, especially red snapper, was shipped to an ever-widening market. In 1913 the inactive navy yard was reopened as a naval air station and became a large aviation training school.

Pop. (1960) 56,752; for comparative population figures *see* table in FLORIDA: *Population.* In that year, for the first time in a federal census, the population exceeded 50,000 and the Pensacola standard metropolitan statistical area (Escambia and Santa Rosa counties, pop. 203,376) was established. (E. C. Jo.)

PENSHURST, a village in the Sevenoaks rural district of Kent, Eng., lies at the confluence of the Eden and Medway, 5 mi. (8 km.) SW of Tonbridge. Pop. (1961) 1,895. The village has some old houses, including timbered cottages of the 15th century. Penshurst Place is the home of the Sidney family, who have held it since 1552. Sir Philip Sidney, the poet and scholar, was born there in 1554. His younger brother, Sir Robert, was created earl of Leicester in 1618. In 1945 William Philip Sidney, created Viscount De L'Isle in 1956, became owner of the house. The mansion is quadrangular and has a court, chapel, and hall (*c.* 1341) with open timber roof and a minstrels' gallery. The state rooms are open to the public during the spring and summer. (FX. H.)

PENSION, a term applied to periodic money payments to a person who retires because of age or disability. The payments usually continue for the rest of the natural life of the recipient. Pensions are provided by governments or by employers either as a direct charge, *i.e.*, by inclusion in the organization's regular expenditures, or as an indirect charge, *i.e.*, by periodic contribution to a pension fund. Pensions are provided by governments for various reasons: (1) as compensation to former members of the armed forces or their dependents for old age, disability, or death (usually from service causes); (2) as old-age retirement or disability benefits for civilian employees; (3) as social security payments for the aged, disabled, or deceased citizens made in accordance with the rules governing social service programs of the country. Pensions under the first heading are of great antiquity. Under the second heading they have been in force in one form or another in some countries for nearly 100 years. Those coming under the third heading are of relatively recent origin, though they are of the greatest magnitude. They are not included in this article but are discussed in SOCIAL SECURITY.

The custom of providing pensions for aged employees who are no longer able to discharge their duties efficiently began during the 19th century in Europe and then spread to other parts of the world. A new development in the 20th century was the appearance of pension plans for workers who were paid by the hour. These plans were often established under trusteeships as a result of union-management negotiations. A further development was the encouragement, by means of a special tax release, of individual self-employed persons to establish their own pension funds.

Pensions are variously viewed as charity, paternalism, deferred pay, rewards for service rendered, or as a means of promoting the general welfare. The fundamental provisions of any pension plan set forth rules of eligibility, conditions for the receipt of pensions, a pension benefit formula, and the source of contributions. The method of funding benefits on the death of the employee and the procedure for withdrawal prior to retirement are sometimes included; in nongovernmental plans the equities on termination are also stated. The cost of pensions granted to citizens by the government for military or civil services is normally met out of taxation, and only rarely is any reserve accumulated for payments beyond the current fiscal year. By contrast, pensions provided as old-age retirement or disability benefits are usually provided by

drawing upon a fund accumulated during the lifetime of eligible persons. Such pensions may be paid to the eligible person or to his widow or children. The accumulation of an adequate fund is a principal concern for such plans and the magnitude of the accumulation may depend upon the number of eligible persons, estimates of their annual earnings, the formula for determining the pension, the nature of secondary pension benefits to widows or children, and the current level of investment income that can be expected from the accumulated money. The true cost outlay of a pension plan can be known only in retrospect and may be expressed as benefits paid plus expenses less the interest earned on the reserve funds. An exact accounting can be completed only long after the source of income is closed. Through the application of actuarial principles, however, it is possible to prepare current estimates of annual contributions required to develop a reserve fund in satisfactory form to meet future liabilities.

UNITED STATES

War Veterans.—The history of military compensation and pensions in the United States goes back to the colonial period. The Pilgrims of Plymouth Colony in 1636, for example, enacted a law providing that "If any person shalbee sent forth as a soldier and shall return maimed hee shalbee mayntained competently by the Collonie during his life." Later, other American Colonies made similar provisions. The Continental Congress also passed laws during the American Revolution promising benefits to those who enlisted in the colonial army, but no funds were approved to finance the program. The first pension law in the United States was passed by Congress on Sept. 29, 1789. It was followed at intervals by other laws and developed into the comprehensive Servicemen's and Veteran's Survivor Benefits Act, which became effective Jan. 1, 1957. (*See* VETERANS ADMINISTRATION, U.S.)

Public Employees and Teachers.—Public employment includes not only the employees of federal, state, county, and municipal governments, but also those of publicly owned corporations, municipal transit companies, the Tennessee Valley Authority (TVA), and the Federal Reserve System. The federal government, with other members of the United Nations, also contributes toward the provision of pensions for employees of international bodies such as the United Nations, the International Bank for Reconstruction and Development, the International Monetary Fund, the International Labour Office, and other similar organizations. The Federal Civil Service Retirement and Disability Fund was established in 1920 and by the early 1960s contained the following main provisions: Employees with 15 years of service might retire at age 62 or continue to work until age 70, at which age retirement was mandatory. Under certain conditions, retirement before age 62 was possible for employees with 25 or 30 years of service. The amount of the pension was determined by the employee's length of service and by his highest five-year average annual salary. The employee received 1½% of such annual salary for each year of service, or 1% of such salary plus $25 for each year of service if this yielded a higher return; the maximum benefit was 80% of the employee's salary. The law also provided for a total disability pension after five years of service, determined by the more liberal of the two formulas above. Employees contributed 6% of their salary to the fund; in case of death or termination of service prior to retirement they (or their beneficiaries) received a refund of their contributions with interest. If, however, at the death of an employee with five or more years of service, a qualified dependent survived (widow or child), one-half of the regular pension was payable to the widow, beginning at age 50. Whether the mother was 50 or not, an additional one-fourth of the regular pension (with certain limits) was payable to each child under 18 years of age; if the child alone survived he received half the regular pension. In case of termination of service after five years the employee might leave his refund and be credited with a vested deferred pension (beginning at age 62) computed on the more desirable of the two formulas mentioned above; this method was automatic if he left after 20 years of service. Various optional death benefit forms of pension were available at retirement. Optional additional employee contributions might be made to augment the regular pension but without direct additional government contributions. According to the law, the pensions and death benefits not provided by employee contributions were to be met from annual appropriations by Congress.

Several special plans for other classes of federal employees were enacted after 1900, including one covering members of Congress. Other plans covered public school teachers in the District of Columbia, policemen, firemen, the U.S. judiciary, certain commissioned services such as the Public Health Service, and organizations such as the Federal Reserve System, permanent TVA employees, and others.

The earliest state pension plans for public employees were those for superannuated teachers, starting in 1896 in New Jersey when a noncontributory plan was adopted. The first contributory state teachers' plan was adopted in Massachusetts in 1913. Pension plans for other state employees followed and were soon established in most of the states. Pension plans for state employees and teachers have many of the characteristics of other pension plans; some have adequate funding arrangements, others fund on retirement, and still others meet costs as pensions are paid. Pension plans for policemen and firemen date back to the beginning of the century, but the large municipal employee plans came somewhat later. While large cities maintain their own plans, in many states the smaller towns and political subdivisions were permitted to participate in the general state employee plan. After 1950, state and local employees and teachers were permitted as groups to come under the federal Social Security Act. Many teachers' plans are money purchase plans, with various modifications; there is a tendency for these plans to be revised and to adopt a "final salary" basis whether they are on a full reserve basis or not.

Discussion of the teachers' plans should include mention of the Teachers Insurance and Annuity Association of America (TIAA), which was incorporated in 1918 in the state of New York as a nonprofit legal reserve life insurance company. The Carnegie Foundation for the Advancement of Teaching financed the foundation of this company and gave it financial assistance for many years in order to put it on a self-supporting actuarial basis. In 1952 TIAA developed an affiliate called the College Retirement Equities Fund (CREF) to implement a new pension idea whereby CREF annuities would vary according to the market value of its fund, which would be invested mainly in common stocks. Teachers could decide what portion of their contributions should go toward the variable annuities of CREF, and the fixed annuity of TIAA, subject to the restriction that at least 50% of such contributions must go to the fixed annuity form.

Employees of Religious Bodies.—The churches at an early date recognized their responsibility for the care of their aged and disabled workers and, in fact, the first pension fund in the United States was founded for such a purpose. The Roman Catholic Church has a long tradition of taking care of all the members of its hierarchy during their dependent years. The Protestant churches' funds have been started for the same purpose; most of them include widows' annuities and orphan pensions as well as pensions to the ministers themselves. More than 20 of the leading Protestant denominations established the Church Pension Conference in the mid-1950s and accumulated substantial reserve funds to meet their liabilities.

Employees of Nonprofit Organizations.—Legislation in 1950 made it possible for all nonprofit organizations in the United States to be covered by the federal Social Security Act subject to election by the individual employer and by at least two-thirds of the employees. As a result, most of the nonprofit employees have been covered by the Social Security Act and have coordinated their own pension plans with an additional benefit. They include such organizations as hospitals, charities, and foundations. Some of them, notably the YMCA and YWCA, have established their own pension plans. In order to make a start in solving the problem of the small nonprofit employer the National Health and Welfare Retirement Association was formed to help in centralizing pension planning and funding. The association was incorporated in January 1945 under the insurance laws of New York State and was made subject to supervision by the state superintendent of

insurance. Benefit payments and guarantees were protected through reinsurance with a well-established insurance company.

Industrial Employees.—By the 1960s there were more than 22,000 private industry pension plans in operation in the United States, including profit-sharing plans that were grouped with the pension plans by the Internal Revenue Service. All these plans had been reviewed and approved by the Internal Revenue Service so that the employer could claim his contributions as tax deductions and the investment income of the fund would be exempt from any federal taxes. Pension trust funds are usually set up with investment control in the hands of the corporate trustee with the assistance of a stock broker or, possibly, of an investment counsel. The administrative work is usually done in the office of the employer.

Most of the large employer pension funds are on a trustee basis. The U.S. Steel Corporation started its fund in this manner in 1911, and the American Telephone and Telegraph Company started one in 1913, though it did not set aside separate funds until 1927. Trust companies did not actually bid for the business until the early 1940s. Passage of the Social Security Act in 1935 stimulated the growth of industrial pension plans. World War II restrictions on wage and salary increases caused workers to turn their attention to so-called fringe benefits that included pension plans. In 1949 pensions were classified by the courts as proper subjects for collective bargaining so that union interest in them was also stimulated. Since pension contributions were deductible for income tax purposes, the excess-profits tax of World War II provided the stimulus for a broad expansion of pension programs. Tax deductions permitted by the Internal Revenue code made it possible for business concerns to provide pensions at a much-reduced real cost.

Insurance companies began to offer contracts for pension plans in the early 1920s. The pension instrument took various forms: the individual policy held by a trustee; the group permanent contract (life insurance to retirement age with maturity then as pensions); the group annuity contract (the direct purchase of units of pension for each year of service rendered); the deposit administration contracts (insurance companies administer unallocated funds with the direct purchase of individual annuities at retirement); and the deposit administration contract with immediate participation guarantee, by which the individual annuities are paid out of the unallocated funds and the guarantee of benefit applies only at the termination of the contract.

It is normally not financially feasible to fund a pension plan unless it is approved by the Internal Revenue Service, for such approval makes the contributions tax deductible. In general, in order to qualify for approval, a fund must show that it is an irrevocable trust, that the funds under it cannot be diverted prior to the satisfaction of all liabilities under the trust, and that it does not discriminate in favour of the more highly paid employees. The plan must also be made known to the employees. There is a substantial volume of rules and regulations that governs the approval of pension plans.

In general, pension plans fall into three main categories. In the first category the pension is related to the salary and length of service of the employee. In the second group the pension is fixed or relates only to the years of service or amount of contributions. In the third category the benefit is dependent entirely on the contributions made by the member or on his behalf. The first type is used generally for salaried employees; the salary upon which the pension is calculated may be either the average salary throughout the period of service, the average salary of the few years immediately prior to retirement or, in a few cases, the salary of the year preceding retirement. When the pension is related to salary the usual practice is to assign a percentage figure for each year of service so that the final pension takes into account both the salary and length of service.

Since the extension of the federal Social Security Act most pension plans make an adjustment to avoid duplication of benefits. In some cases, the adjustment is a straightforward deduction for the whole or part of the Social Security benefit. A more common method, however, is a determination of the benefit by means of two percentages, one of which, the lower, applies approximately to that portion of wages and salaries subject to Social Security contributions, and the other, the higher, applies to all wages and salaries above that. As a result, whenever the level of wages subject to the Social Security tax is raised, a question arises about making corresponding adjustments in the private pension plan. Such adjustments, if they are made, are generally made only after some delay, which often has the effect of skipping one social security adjustment and catching up on the next.

Continuing depreciation in the purchasing power of the pension dollar due to constantly rising prices created during the 1950s some concern with the long-run adequacy of fixed pensions. The variable annuity plan was offered as a partial answer. Under such a plan, a portion of the total contribution is placed in a fund that is invested in common stocks. The dollar amounts invested are measured in terms of "units of accumulation" and benefit rights are expressed as "units of annuity." The value of each type of unit varies with the market price of the securities comprising the fund. All the variable annuity plans involve payment of a pension in annuity units that vary each year with the market price of the annuity fund as of a specific date. The underlying assumption is that the movement of prices of the common stocks in the fund will correspond to the movement of prices in general and will thus offer the pensioner some protection against loss of purchasing power. So far as is known, all of the variable annuity plans subscribe to the principle that at least 50% of the contribution should go into fixed annuity benefits.

Pensions for workers who are paid by the hour are usually not based directly on earnings. Most of the plans negotiated by unions provide a benefit expressed in terms of dollars per month per year of service, sometimes with a total dollar ceiling. While many of these plans, notably in the automotive industry, have been directly negotiated in the form of specified benefits, many of the other joint employer-union plans have been negotiated in terms of contributions of a certain number of cents per hour with the benefit to be determined on the basis of actuarial advice with full regard to all the circumstances in the case.

GREAT BRITAIN

The actuarial theories of pension plans and many of the current practices in connection with them originated in Great Britain, though the United States has initiated some modern improvements. The self-administered pension plan, for example, was developed in Britain but the corporate bank-trustee type with its more aggressive approach to the investment aspects had its origin in the United States. The insurance company contracts for group annuities and deposit administration are also due to American initiative. Generally the interchange of ideas and personnel between the two countries has been to the advantage of both. The conditions for approval by the tax authorities in Great Britain are practically identical with those in the U.S. In Great Britain overall limits are placed on the size of the maximum pension and its relationship to the salary at retirement. These limits are larger if the plan, or scheme, as it is generally called in Britain, is noncontributory than if the employees contribute.

A major difference between the U.S. and Great Britain is that British employees may claim contributions to an approved fund as a tax deduction. Pensions for self-employed persons are also granted tax privileges, if they are established by an approved contract with an insurance company, a friendly society, or a trustee. For those born in 1916 or later, contributions in general may not exceed £750 a year or 10% of "net relevant earnings." For those born in 1907 and earlier the limits are £1,125 or 15%. The contract must provide for an annuity benefit to begin after age 60 and before age 70 and not to be surrendered, commuted, or assigned. A great number of pension plans for salaried employees contain a benefit formula basing the pension on the average salary of the three or five years immediately preceding retirement. This is in large measure due to the standard set by the Local Government Superannuation Acts 1921–1953, which established uniform pension benefits and contributions for local government employees throughout Great Britain. In 1953 the Ministry of Pensions,

which dated from 1916, was combined with the ministry of national insurance.

Civil Service.—The pension system for British civil servants is governed by special acts of Parliament. The cost of the current pension roll is a charge on the national budget, and no funds are accumulated other than for widows and orphans benefits. Only established (*i.e.*, permanent) staff members are eligible for pensions, and contributions are required only to provide benefits for widows and orphans. A disability pension is payable on retirement due to ill health after ten years of service. The minimum retirement age is 60, after ten years of service, but early retirement may take place after age 50. In the latter case the pension begins at age 60 unless immediate payment is allowed on compassionate grounds.

Pensions are computed at the rate of one-eightieth of the salary at time of retirement for each year of reckonable service. Lump sum payments are made in addition at the rate of three-eightieths of the retiring salary for each year of service. Not more than 40 years of service up to age 60 may be reckoned, but those who serve after the age of 60 may count further service subject to a maximum of 45 years. Pensions paid to those who retire because of ill health are calculated on the basis of years of service, except that for those retiring with between 10 and 20 years of service it is based on 20 years, or on the service the employee would have completed had he served for five years after the retiring age, if that is less. The average salary of the last three years of service is used in all these calculations. Temporary service after the age of 18 counts as established service if rendered after July 1949; if rendered before that date it counts as one-half. Officers who serve overseas in unhealthful climates receive additional pension rights. The system provides for transfers of staff between the civil service and many other forms of public employment.

The pension for a widow is one-third of the civil servant's own pension, or, if he dies while still serving, of the pension he would have been paid if he had retired because of ill health on the date of his death. The widow may also be paid a children's pension varying according to the number of children from one-twelfth of the officer's pension (for one child) to one-third (for four or more children). If there are children but no widow, the children's pension is at a higher rate, varying from one-sixth to one-third of the officer's pension.

About half the estimated cost of these benefits is paid by the contributions of civil servants, made either by periodic deductions of one-eightieth of salary during service, or by a deduction from the lump sum or death gratuity payable at the end of the service. All married men must participate in this plan. A retiring civil servant may also, subject to his passing a medical test, surrender up to one-third of his pension to provide an actuarially equivalent pension for his wife or some other dependent. There is also a voluntary contributory plan for pensions to dependents other than widows and children. There is also provision for short-service gratuities on death, withdrawal, or dismissal before completion of ten years of service. A gratuity is also paid to women civil servants with not less than six years of service who resign or marry.

Armed Forces.—Retirement pay and pensions for officers and men in the Navy, Army, and Air Force are governed by royal warrant or other appropriate prerogative instrument. The basis of the officers' plan is a series of standard rates of retirement pay related to rank. These rates are payable to officers who are forced to retire either because they have reached the compulsory retiring age for the rank, because they have not been promoted, or because no further employment is available for them. Normally, 20 years of service is necessary to qualify for retirement pay; the service needed to qualify for the full standard rate ranges from 20 years in the lowest rank to 30 years in the highest. The rates take account of the relatively early retirement of many officers and are designed to provide some compensation for shortness of career. Officers permitted to retire at their own request receive reduced rates of retirement pay. After 1950 officers also became eligible on retirement for a lump-sum terminal grant in addition to retirement pay or pension, at the rate of three times the retirement pay. The rates of retirement pay, pension, and terminal grant are published in the command paper entitled *Services Pay and Pensions* (HMSO, London). There is a basic scale of pension for men in various ranks completing 22 years of service, with additions for longer periods of service. The scale is based partly on length of service and partly on rank. Retirement pay and pensions for members of the women's services are approximately two-thirds of those for men.

Provision is also made for pensions for widows and orphans of regular members of the forces. The plan is noncontributory and covers widows of officers and other senior ranking men who had completed enough service at the time of death to qualify for service pension. The plan also includes other ranks below staff sergeant, but with a longer qualifying period.

Judges.—English judges receive pensions close to £3,000 per year and in Scotland nine-sixteenths of their salary at the time of retirement if they have completed 15 years of service or if they retire because of permanent ill health. County court judges, stipendiary magistrates, and the two full-time sheriffs and sheriff's substitute in Scotland receive pensions based on their salaries and length of service. A lump sum is also paid to the retiring judges, and from it is deducted a contribution to the widows' and children's pension plan. The lord chancellor of Great Britain receives a pension of £3,750 no matter how short his service. He usually continues to sit judicially in the House of Lords without salary.

Local Government.—The Local Government Superannuation Acts provide pensions on a uniform basis for employees of municipalities, counties, and kindred political subdivisions. Certain of the larger authorities such as the London County Council, the City of London, Manchester, and some London boroughs operate their own pension schemes, which are similar. Superannuation funds may be operated by a single municipality or county, which may admit an authority within its boundaries, or by local authorities in combination with one another. Employees are classified as officers (*i.e.*, salaried employees) or servants (wage employees). All full-time officers are compulsorily covered but servants and part-time officers are included only at the option of the employing authority. Retirement may occur at age 65, at age 60 after 40 years of service, or at an earlier age due to ill health after 10 years of service. Pension credits can be earned to the age of 70, subject to a maximum of 45 years of service.

The pension is one-eightieth of the average salary of the three years immediately preceding retirement multiplied by the years of service (noncontributory service, if any, counts at half rate). A lump-sum grant of three times the annual pension is also made, but it is reduced to one year's pension if the pensioner contributes to the widows' pension. The widows' pension is one-third of the members' pension and continues to the end of the widow's life.

Officers contribute 6% and servants 5% of their current salaries. These contributions are refunded upon death or upon withdrawal prior to retirement. The employing authority pays an equal contribution to finance current pensions and makes an annual payment to make good the deficiency shown at each quinquennial valuation. There is a system of transfer values for preserving pension rights on transfer to the Civil Service and other forms of national employment.

National Health Service.—A program is in operation under the Ministry of Health for employees of the regional hospital boards and for medical and dental practitioners. Pension formulas for members and widows are similar to those provided under local government schemes. Contributions are 6% for the employee and 8% for the employer (5% and 6% in the case of manual workers). The program is not funded but provision is made for preservation of rights on interchange with other superannuation plans.

Teachers.—The teachers' superannuation plan is a national plan applicable mainly to teachers in schools aided by government grants. The main benefits are pensions and lump sums payable at the age of 60 or upon retirement at a later age. The plan also provides disability pensions after ten years of service and gratuities payable on death after five years of service. Teachers contribute 6% of their salary but the plan is not funded. It is to the

exchequer that contributions are paid and from which benefits are received.

Policemen and Firemen.—Pensions for policemen and their dependents are provided under acts of Parliament. Pensions are normally calculated on the average pay during the three years preceding retirement and an ordinary service pension rises from one-half of average pay after 25 years of service to a maximum of two-thirds pay after 30 years of service. Members retiring on grounds of health after 10 years of service are granted pensions on a proportionate basis. Injury in line of duty qualifies an officer for an ill-health pension even if he has less than 10 years of service, and it may be supplemented if his earning capacity is affected. A widow's pension is granted on the basis of the husband's pay at the time of his death or as a lump-sum award according to his rank. Children's allowances are payable with the lump-sum award. Policemen pay contributions up to 6½% of their pay toward the cost of pensions and the balance is borne in equal shares by the exchequer and by the local government employing authority. Broadly similar provisions apply to firemen under a separate act. Only 25% of the rest of the cost of firemen's pensions is met from government sources.

The Civil List.—In this category are small pensions (£100 to £150 per annum) granted by the sovereign upon the recommendation of the first lord of the treasury. They are granted for personal service to the crown, for performance of duties to the public, or for useful discoveries in science or attainments in literature and the arts. The maximum annual allotment is £5,000.

Perpetual or Hereditary Pensions.—Pensions of these types were freely granted in the 17th and 18th centuries but as the result of parliamentary agitation they were gradually extinguished by commutation. Thereafter no further perpetual pensions were granted, but capital sums were voted to certain distinguished commanders after World War I. After World War II, neither capital sums nor perpetual pensions were granted, but only titles as a recognition of distinguished service.

Political Pensions.—The only national political pensions are those payable to former prime ministers. These pensions are regulated by acts of Parliament. Former prime ministers are entitled to a pension of £2,000 a year provided they are not receiving a salary of more than £750 drawn from public funds. In addition, the House of Commons Members Fund enables payments to be made to former members of the House of Commons or to their widows or children if they are in reduced circumstances. The payments are made from funds provided solely by compulsory contributions of members of the House of Commons. Public money is not involved.

Ecclesiastical Pensions.—Archbishops, diocesan bishops, and suffragan bishops of the Church of England whose sees are in England are entitled to receive pensions on retirement at or after the age of 70 under a contributory program governed by the Episcopal Pension Measures, 1926 and 1945, and administered by the church commissioners. All other Church of England clergy rendering ecclesiastical service or holding educational, charitable, or public appointments in England are entitled to receive pensions on retirement at or after the age of 70 under a noncontributory program governed by the Clergy Pensions Measures, 1948 and 1954, and administered by the Church of England Commissioners. Under this plan there are reciprocal arrangements for overseas service in many other countries. The Church of England Pensions Board also administers contributory programs for pensions for widows and dependents and for deaconesses and lay workers.

OTHER COUNTRIES

The development of pension plans in countries throughout the world has been very uneven. Some countries rely heavily on government schemes of social security and others place more reliance on private pension plans. In most countries social security and private pension schemes exist side by side and are integrated in a variety of ways. The section that follows indicates briefly the pension developments in Canada, Australia, and a number of countries in Europe.

Canada.—Private pension plans in Canada are similar to their counterparts in the United States. Employees' contributions up to $1,500 are tax deductible. The employer may deduct as the result of the 1958 Income Tax Law the whole or any part of past service liabilities to the extent that he made a payment in the year; contributions for current service are deductible up to $1,500 per employee. In 1957 Canada introduced a pension tax allowance for self-employed individuals. According to the law, a Registered Retirement Saving Plan may be set up and may enjoy freedom from taxes on interest and capital appreciation. The maximum yearly tax-deductible contribution under such a plan is $2,500. The same privileges are extended to an individual covered by a pension; he may contribute 10% of his salary up to a maximum of $1,500 less his own pension contributions. The plan must provide an annuity beginning not later than his 71st birthday and must be based on a contract that may not be surrendered for cash or used as security for a loan. Each plan must be individually registered by the government and be issued by an approved underwriter—generally an insurance company, the government annuity branch, a trust company, or a mutual fund.

In 1963 the Liberal government introduced a new pension plan but it was opposed by the governments of Ontario and Quebec, which had pension plans of their own in process of adoption.

The Canadian government has issued annuity contracts since 1908. Group contracts on a formal basis have been issued since 1938. The maximum annuity issued is $12,000 a year, and there is no cash value unless the annuity is greater than $10 per month.

Australia.—The government old-age pension, which is subject to a means test, is reduced shilling for shilling for the excess of any private pensions over £3 10*s.* per week. This provision of the law influences employers to provide lump-sum benefits on retirement, mainly by means of insurance. Employee contributions to private pension plans up to £200 a year are deductible when calculating personal income tax. Employers obtain a deduction of £100 or 5% of the employee's salary, whichever is greater, for each employee if the plan is approved by the commissioner of taxes.

Belgium.—Private pension plans in Belgium are nearly all instituted to supplement government pensions for salaried employees. The majority of the plans are based on career earnings. Only a few base benefits on a more current average salary. Both employers and employees obtain tax deductions for contributions to properly constituted plans. Under a 1956 compulsory pension scheme, self-employed persons are required to establish a pension account either by depositing funds or by obtaining an annuity policy providing a pension of 18,000 francs for a man at 65 (one-half to the widow) or 12,000 francs for a woman at 60. Payments and pensions are raised or lowered if the retail-price index moves up or down at least 5%.

France.—In addition to the regular old-age pension, engineers and management personnel have a supplementary retirement system (known as Régime Complémentaire de Retraites des Cadres) organized for various types of employment. Contributions are paid on that part of the employee's remuneration between the ceiling for old-age contributions—660,000 francs and a maximum of 3,204,000 francs. The tax rate starts at 8% (6% by the employer and 2% by the employee) and may rise to any figure between 8% and 16% according to the circumstances of the institution. Retirement normally takes place at the age of 65 if the employee has completed ten years of salaried employment. A widow, if she is over 50, receives 60% of the participant's pension, and orphans receive 20%. All pensions are determined in "pension points" by the AGIRC (L'Association Général des Institutions de Retraites des Cadres). Rights acquired each year in points are determined by dividing the contribution for the period by a reference salary which is the mean of all salaries subject to contribution in the period (value about 650 points). Years prior to 1947 have a value between 40 and 120 points per year. The pension is determined by multiplying the sum total of points accumulated by a participant by a point value for each year. The point values are obtained by dividing the total contributions to the institution during the preceding year, less expenses and 10% for a stability re-

serve, by the present value of future charges in the institution over the next ten years.

Effective April 1, 1957, a system similar to the AGIRC was set up for non-Cadre salaried employees. It is known as UNIRS (Union National des Institutions de Retraites des Salaries). Membership is voluntary and the system after two years of operation covered nearly 5,000,000 employees. Total contributions vary from 2½% (employer 1½%, employee 1%) to 4% (employer 2.4%, employee 1.6%) and are paid on total earnings. There are many supplementary private pension plans, most of which are on a pay-as-you-go basis. Both employer and employee contributions to all pension plans are tax deductible.

Federal Republic of Germany.—Such private pension plans as are established in the Federal Republic of Germany either cover personnel not included in the public pension system adopted in 1957 or supplement the public pension. Employers may take a tax deduction for contributions, the amount depending upon the type of plan. Employees may obtain a tax deduction for contributions except that, in states where the employer does not pay the special 8% premium tax, the employee cannot claim that there is any insurance element in the contribution. Most private plans are not insured.

Netherlands.—Private plans are numerous in the Netherlands and must be formally established and actuarially sound before being approved. Assets must be separated from the employer's assets, but up to 10% of the fund may be used to buy the employer's stock. Employers may deduct contributions as a business expense, and in addition they may deduct sums placed in an earmarked retirement reserve not separated from their assets. Employees may deduct contributions to an approved fund, and in addition may deduct premiums to an individual annuity up to 3,600 florins a year. Private plans are usually designed to produce a pension of about 70% of final pay. A general pension plan for widows and children became effective in 1960.

Norway.—Both private plans and group pension insurance plans exist in Norway, but the number of private funds is small. There are also non-actuarial funds that exist to accumulate money to set up private plans in due course. A further large pension element includes the collective plans set up by the large professional societies of which the Medical Society and the Dentists Society are the largest. Norwegian pension plans provide old-age pensions, disability pensions, and pensions for widows and children. Old-age pensions amount to approximately 60% of the average pay of the last five or ten years after 30 years of service. It is reduced by one-thirtieth for each year the total service falls short of 30 years. A widow's pension is usually 60% of the pension the husband was receiving or would have received had he continued in service to pension age at the pay he was receiving at the time of his death. The children's pension is 40%, 60%, 75%, 90%, and 100% of the widow's pension for one, two, three, four, five or more children, respectively. If the child has no mother the pension is doubled. The disability pension is paid during disability due to sickness or accident that has continued for three months; the amount is the fraction of the old-age pension representing the degree of disability. The disability pension is increased 10% for each pensioner's child under 18. About one-half of the pension plans do not include disability pensions. Retirement age ranges from 67 to 70 for men and from 65 to 67 (sometimes 70) for women.

Sweden.—Practically all supplementary pension plans in Sweden are underwritten by Svenska Personal-Pensionskasse, which has a virtual monopoly of pension insurance. These benefits are actuarially calculated and reserves are accumulated. Supplementary pension plans for salaried employees are contributory and provide benefits geared to salary. Wage-earners' benefits, if any, are a flat annual amount and are arranged in some way so as not to reduce the governmental supplementary "means test" pensions. There are a number of cases of supplementary plans for wage earners negotiated on an industry-wide basis by unions and employers.

PENSIONARY, the designation, indicating that he drew a salary, of an official of importance in Netherlands' history.

From the 15th century onward the name pensionary, with *clerc* and advocate as occasional alternatives, was given to the secretary of certain town corporations in the Netherlands. The pensionary conducted the town's legal business and was its representative at meetings of the provincial estates. The office originated in Flanders. The first towns in Holland to appoint a pensionary were Dordrecht (1468) and Haarlem (1478).

The order of nobles in the estates of Holland also had a pensionary to act on their behalf in the estates. As the nobility had the right to preside over the assembly, this pensionary was actually its chairman. This office was in Holland combined with that of "land's advocate," that is, legal adviser to the estates, an official whose appointment was found necessary for the first time in 1544. After 1619 the name "land's advocate" was changed into *raadpensionaris* or councilor pensionary, usually translated into English as grand pensionary. The first to give the office its full importance was Johan van Oldenbarnevelt (*q.v.*), who from 1586 to 1619 dominated the estates of Holland and through them the States General: all correspondence passed through his hands, and he in fact controlled foreign policy; but his authority was the product of circumstances and of his personal influence and was not founded on any constitutional ruling. After his execution the office lost its importance until Johan de Witt (*q.v.*), grand pensionary from 1653 to 1672, restored its glory during the "First Stadholderless period." After him the best-known grand pensionaries of Holland were Antonius Heinsius (*q.v.*; 1689–1720) and L. P. van de Spiegel (1787–95). The office was abolished in 1795. The estates of Zeeland also employed a grand pensionary, but this official was much less important than his Holland counterpart.

(E. H. K.)

PENSTEMON, the beardtongue genus of perennial herbs (family Scrophulariaceae), comprising about 250 species, chiefly natives of North America, with showy open-tubular flowers. Noteworthy species are *P. laevigatus* (smooth beardtongue), *P. digitalis* (foxglove beardtongue) and *P. hirsutus* (hairy beardtongue) of the eastern and southern states; *P. alpinus* (alpine beardtongue), *P. cyananthus* (blue beardtongue) and *P. barbatus* (bearded penstemon) of the Rocky mountain region; and *P. antirrhinoides* (snapdragon beardtongue), *P. difusus* (spreading beardtongue) and *P. centranthifolius* (scarlet bugler) of the Pacific states; these and various others are more or less cultivated. The penstemon of the florist has, however, sprung from *P. hartwegi* of Mexico and *P. cobaea* of southwestern United States and possibly some others.

RUTHERFORD PLATT

PENSTEMON, KNOWN ALSO AS BEARDTONGUE

The plants endure mild winters unharmed in favoured situations. They winter safely in cold frames, protected by mats or litter during frost, but tend to die out in a year or two, especially if

grown in open sunlight. They produce seed freely, new kinds being obtained by that means.

PENTAGON, a large five-sided building in Arlington county, Virginia, near Washington, D.C. It was built in 1941–42 to bring under one roof the U.S. war department offices then housed in widely scattered buildings. After World War II it became the headquarters of the department of defense, including all three services—army, navy and air force. The largest office building in the world, the Pentagon covers 34 ac. (including a 5-ac. central court), offers 3,700,000 sq.ft. of usable air-conditioned floor space and provides work space for about 30,000 persons, military and civilian. Built of structural steel and reinforced concrete, with some limestone facing, the entire structure cost $83,000,000.

The Pentagon consists of five concentric pentagons or "rings" with ten spokelike main corridors connecting the whole. (*See* WASHINGTON, D.C., for photograph.) With only five floors, plus a mezzanine and basement, the height of the building is far less than its horizontal dimensions. A huge concourse, larger than two American football fields, provides a shopping centre for Pentagon workers. Beneath the concourse are bus and taxi terminals. Parking areas adjacent to the building can accommodate over 8,000 cars. A heliport for the Pentagon was added in 1956.

See Gene Gurney, *The Pentagon* (1964). (H. C. T.)

PENTASTOMIDA (LINGUATULIDA) are a small group (usually considered a class) of wormlike, bloodsucking arthropods that live as internal parasites of vertebrates. The body of an adult is externally ringed—and in many species looks like a thick string of beads—though there is no true internal segmentation. The alternate name Linguatulida or "tongue worms" is descriptive of the linguiform or tongue-shaped body of other species. Although some authorities consider the pentastomes a separate phylum, certain characteristics point to their very close arthropod relationship: (1) jointed legs in the embryo; (2) ecdysis or molting in the larval stage; and (3) the presence of breathing pores scattered over the body.

The name Pentastomida refers to the five openings arranged in a crosswise line on the head; the centrally located one is the oval, chitinous mouth, and the other two flanking pairs are the openings of pockets or sacs containing protractile hooks. The body is elongate and cylindrical in most species, a few being short and somewhat flattened. Adjoining a short head region is the long abdomen (from about ½ to 6 in. in length) marked with a variable number of superficial rings that do not represent true internal body segments and devoid of appendages. Although reproductive, nervous, and digestive systems are present, there are no organs of circulation or respiration. Mouth parts are lacking, and the digestive canal opens posteriorly. Sexes are separate, and the females are several times larger than the males.

PHOTOGRAPH BY COURTESY OF HOWARD R. HILL

VENTRAL VIEW DRAWING OF HEAD OF POROCEPHALUS AND PHOTOGRAPH SHOWING HEAD OF ARMILLIFER MONILIFORMIS EMBEDDED IN LUNG TISSUE OF PYTHON HOST

These bloodsuckers usually attain their adult stage within cold-blooded vertebrates, the nymphal forms occurring in warm-blooded vertebrates upon which the adult hosts feed. Adults live in the air passages of their host, whereas nymphs are most frequently found encysted in the liver of their host. Development is usually combined with a change of host.

The number of known species is over 50, and they are not always restricted to a single host species. *Raillietiella furcocerca orientalis* is a common parasite of snakes in the Eastern Hemisphere. *Reighardia sternae* is a cosmopolitan parasite of gulls and terns. In America, *Kiricephalus coarctatus* is often found in the air passages of snakes.

Linguatula serrata, usually found in dogs, wolves, and several other mammals, and *Armillifer armillatus* have occasionally been found in man. The eggs of *L. serrata* are scattered in sneezing, and the larvae develop in the viscera of the intermediate host—usually a rabbit, rat, or sheep. After several molts the nymphal stage is attained, which may last for two or three years. Man can serve both as an intermediary and as a final host.

The adult of *Armillifer armillatus* is a common parasite in the lungs of large snakes in the Eastern Hemisphere. Pythons often become infected by devouring an infected mammal. In man, infection takes place by swallowing eggs scattered over vegetables or in water. The encysted larvae settle in various organs, and a heavy infection may lead to grave disturbances and may even result in death.

Pentastomida are divided into two orders: (1) the Cephalobaenida, with two families and four genera (*Cephalobaena, Raillietiella, Reighardia*, etc.); and (2) the Porocephalida, with two families and 14 genera (*Porocephalus, Linguatula*, etc.). These two orders are distinguished by the structure of their reproductive and nervous systems, the Cephalobaenida being the more primitive.

One of the best treatises is by R. Heymons, "Pentastomida," in Bronn's *Klassen und Ordnungen* (1935). For an extensive list of literature *see* Howard R. Hill, "Annotated Bibliography of the Linguatulida," *Bull. S. Calif. Acad. Sci.*, vol. 47, pt. 2 (1948). (H. R. HI.)

PENTATEUCH. The name Pentateuch (from the Greek *pentateuchos biblos*, "book of five volumes") designates the first five books of the Old Testament—Genesis, Exodus, Leviticus, Numbers and Deuteronomy—which embody the Law of Moses and hence are called also Torah. The Pentateuch consists of narratives into which collections of laws are interpolated; the narratives begin with the creation of the world and conclude with the death of Moses, just before the entrance of the Israelites into the land of Canaan. They relate the primitive history of man, the stories of the patriarchs, the exodus of the Israelites from Egypt and their journey to Canaan, and the institution of the Israelite Covenant and laws at Sinai.

Development of Criticism of the Pentateuch.—Jewish and Christian tradition until the 19th century, with a few rare and uninfluential exceptions, attributed the Pentateuch to Moses. The French physician Jean Astruc suggested in 1753 that Moses compiled Genesis from two documentary sources, one of which employed the divine name Yahweh and the other the divine name Elohim. Astruc did not intend to question the authorship of Moses; but his introduction of the divine names as a criterion of documentary sources gave the impulse to the literary criticism of the Pentateuch which engaged almost every major biblical scholar of the 19th century.

The text of the Pentateuch exhibits numerous traits which indicate a complex literary origin. There are two creation accounts (Gen. i, 1–ii, 4a; ii, 4b–24). The account of the deluge (Gen. vi, 5–ix, 17) shows evidences of two accounts which have been compiled into one (the number of animals taken into the ark, the duration of the deluge, the two entrances of Noah into the ark, the blessings and covenant pronouncements after the deluge). Ex. iv, 19 is the logical sequence of Ex. ii, 23. The expulsion of Hagar by Abraham (Gen. xvi; xxi), the call of Moses (Ex. iii; vi) and the miracles of the quail and the manna (Ex. xvi; Num. xi) are narrated twice. The wife of a patriarch is taken into the harem of a foreign ruler, or threatened with this, three times (Gen. xii; xx; xxvi). When the text is studied closely, other similar phenomena are observed. If these passages are analyzed and grouped, three strands of narrative emerge, each with distinctive characteristics of vocabulary and style, of which variation in the use of the divine names is only one.

Proceeding on these data, J. G. Eichhorn (1781) distinguished various sources in Genesis. K. D. Ilgen (1798) observed the source called Elohist could not be considered as a single source but must be divided into two. Geddes (1792), Vater (1802–05)

and De Wette (1805) proposed the "theory of fragments," which assumed that there was no single document in the Pentateuch; they found in it a compilation of fragments of numerous different documents. The most important contribution of De Wette was his isolation of Deuteronomy as a distinct source. The unity of the sources, however, was too evident to be denied; and Ewald (1823) and De Wette (1840) adopted the "complementary theory," which assumed that one basic document was enlarged by the addition of fragments from other sources. This basic document was called the Elohist. Subsequently H. Hupfeld (1853) restored Ilgen's theory of two Elohist documents. One of these (the Priestly source of later scholars) he called the First Elohist as the oldest; the Jahwist document followed, and the Second Elohist was the most recent. With the addition of Deuteronomy the lines of the four-document hypothesis were drawn.

The decisive contribution was made in 1865 by Graf, who proposed that the First Elohist was actually the most recent of the sources and was postexilic, the work of the Jerusalem priesthood. He introduced the sign "P" to designate this source. Kuenen (1869) announced that he had reached the same conclusions independently. Julius Wellhausen, in a series of works published between 1876 and 1901 and remarkable for brilliant and persuasive clarity, presented this hypothesis both to scholars and to the general public, and after 1900 it was almost universally accepted. Wellhausen's own contribution was a theory of the historical and cultural evolution of Israel and its religion, which explained the growth of Israelite belief as a rectilinear progress from the primitive polytheism of early Israel through the ethical monotheism of the prophets, the great creative thinkers of Israel, to the formal legalism and sacerdotalism of postexilic Israel. This theory of the evolution of Israel cannot now be sustained; Wellhausen worked at the beginning of the period of the great discoveries relating to the history and culture of the ancient near east, and these discoveries have rendered the theory as a whole impossible. But since in the early years of the 20th century the theory of the religious evolution of Israel was not always distinguished from the theory of the literary origins of the Pentateuch, many conservative theologians of all churches regarded Wellhausen's theory as an attack on revealed religion.

Documentary Theory.—In its classical form the documentary theory finds the Pentateuch to be a compilation of four documents: the Jahwist (German spelling; J), composed in the 9th century B.C.; the Elohist (E), composed in the 8th century B.C.; the Deuteronomist (D), composed in the 7th century B.C.; and the Priestly document (P), composed in the 5th century B.C. The Jahwist is Judahite, the Elohist Ephraimite in origin. These two versions of early Israelite tradition were fused into one document after the fall of Israel in 721 B.C. Deuteronomy was added after the exile. These were amalgamated with the Priestly source into the present Pentateuch about 400 B.C.

This hypothesis did not explain all questions of detail. Subsequent work was devoted to further analysis of the documents, to the isolation of other sources and to a more precise dating of the documents. The analysis of the documents was pushed by some scholars to the point where it issued in a new "fragment theory," and analysis based on minutiae has been proved exaggerated; the unity of the sources in some form must be explained. It is generally accepted that the documents represent strata of material rather than single unified compositions, and that the processes of redaction and expansion are too complex to permit a definitive analysis of the entire text. For the same reasons a precise date for each of the sources is scarcely possible.

Later critics, especially those of the Scandinavian school, have affirmed that the entire documentary hypothesis is false, since it does not reflect ancient methods of composition and transmission. This school asserts the primacy of oral tradition; the "documents," they say, are modern historical conceptions. While the oral traditions may be designated by the symbols J, E, etc., these actually are cycles of oral traditions not written until a relatively late date, postexilic in any case. Most contemporary critics believe that the Scandinavian school exaggerates the place of oral tradition; ancient near eastern culture offers numerous examples of the collection of traditions in writing. It is altogether probable, however, that most of the traditions of the Pentateuch were orally composed and orally transmitted in their early stages of development.

Later criticism also emphasizes the importance of literary form and of the "situation in life" in which the traditions arose. Noth, von Rad and others see in these traditions not mere popular or tribal memories, but traditions which have arisen from cultic recitals. On such great feasts as Passover the ritual included a recital of the saving deeds of Yahweh on behalf of Israel. These took variant forms in different cultic centres; the traditions of northern Israel, for instance, make Jacob prominent, while the traditions of Judah give greater prominence to Abraham. But the traditions all have in common that they are "history of salvation," a profession of the faith of Israel. Scholars agree that the study of any particular tradition must take account of its preliterary history as far as this can be traced: its local origin, its clan or tribal emphasis, its cultic significance. The compilers of the written sources were not creators; they found well-formed oral traditions which they arranged into a new literary unity.

Jahwist.—The literary composition of the Jahwist tradition probably may be placed in the reign of David or of Solomon as an expression of the new unity and prosperity of Israel under the monarchy. It began with the creation of man in Eden and contained the stories of the fall, primitive man, the deluge and the tower of Babel. The patriarchal stories of the Jahwist give the chief place to Abraham, who dwelt in the south, the later territory of Judah; it incorporates selected materials from the northern cycles of Jacob and Joseph, in particular the story of the marriages of Jacob and the births of the eponymous ancestors of the tribes. In the story of Joseph the Jahwist makes Judah the protagonist of the brothers. Analysis of the sources in Exodus and Numbers is more difficult; the Jahwist appears to have made Kadesh-barnea the focal point of his account of the wandering.

The Jahwist has been called the national epic of Israel. His are some of the best-known pieces of biblical narrative; they are concrete, vivid and moving. His conception of the deity is the most anthropomorphic of all the sources, and his human characters are portrayed with earthy realism. In spite of the childlike and primitive traits of his narrative, some of the most profound theological ideas of the Bible are expressed in such stories as those of the fall, the deluge, primitive man, the destruction of Sodom. Israel escapes from the curse, which he traces to human origins, by accepting the blessing granted to Abraham and to his seed; and the promises are obviously fulfilled in the peace and prosperity of the monarchy of David.

Elohist.—Compared to the Jahwist, the Elohist appears to be a torso; no doubt the document was edited by the Judahite compilers when it was fused with the Jahwist. The Elohist begins with Abraham and emphasizes Covenant rather than blessing. It contains at length the stories of Jacob and Joseph, the heroes of the northern tribes. The story of the exodus is centred about the Covenant of Sinai. The Elohist lacks the vividness of the Jahwist; his conception of the deity avoids grosser anthropomorphisms, and his human characters are more idealized. The literary composition of the Elohist is to be placed after the establishment of the divided kingdom; like the Jahwist, it is an expression of the traditions of the kingdom, with more emphasis upon the northern element in those traditions.

Priestly.—The Priestly source is often called a précis of history. It begins with an elaborate account of creation (Gen. i); but elsewhere it appears as brief notices, genealogies and lists, and the narrative is prolonged only when religious institutions are concerned, many of which it retrojects to earliest times. It has created an artificial chronological scheme. Its style is dry and pedestrian and easily detected. The historical sketch of the Priestly source is intended as framework for the priestly collection of law.

Law and History.—In addition to the priestly collection of laws there are other collections of laws of various date and provenance. A historical prologue usually stood at the beginning of ancient near eastern legal collections. This is in a sense the

conception which governs the compilation of the Pentateuch. Israelite law arises out of the history of Israel, but not its secular history; law is incorporated into the history of the saving deeds and the revelation of Yahweh, who elects Israel as his people and lays down as terms of his Covenant the laws by which Israel should live.

In the history of Judaism the Torah, the law of Moses, as the Pentateuch was designated, was the dominant influence. The Torah was the exclusive object of study and interpretation in the rabbinical schools, whose interpretations were collected in the Talmud. The Pentateuch is designated as law in the prologue of Ecclesiasticus (written about 132 B.C.) and frequently in the New Testament. From the Pentateuch arises the characteristic Jewish conception of Israel as a people chosen by God, delivered and preserved by his saving deeds, established in a commonwealth by him and living under his revealed law. This conception of Israel as the people of God was incorporated into the teaching of primitive Christianity and applied to the church.

See BIBLE and articles on the separate books; for the special problems of DEUTERONOMY *see* that article; on the extension of the sources of the Pentateuch in subsequent books of the Old Testament *see* HEXATEUCH. *See* also references under "Pentateuch" in the Index.

PENTATHLON is an athletic contest involving five distinct types of competition (from the Greek *penta*, "five," and *athlon*, "contest"). In the ancient Greek Olympics, the pentathlon included a race the length of the stadium (about 210 yd.), the broad jump, discus throw, javelin throw, and a wrestling match between the two athletes scoring highest in the previous four events.

This Greek pentathlon was adapted for modern track and field competition by setting the sprint distance at 200 m. and by substituting a 1,500-m. run for the wrestling match. The event was introduced to the Olympic Games in 1912 but discontinued after 1924.

The modern or military pentathlon, which has been included in the Olympic Games since 1912, demands far greater diversity of skills than its track and field counterpart. It requires each contestant to perform the tasks that might confront a mounted courier under historical battle conditions.

Entrants are required to: (1) ride a strange horse, selected by lot, over a 5,000-m. obstacle course; (2) engage each of his rivals in an épée fencing match; (3) shoot with pistol at a silhouette target; (4) swim 300 m.; (5) run 4,000 m. on an unfamiliar cross-country course. The competition takes five days.

Each nation enters three contestants and they are scored according to a point table established by the International Pentathlon Union. Team prizes are awarded by adding up the three individual scores. World championships, under International Amateur Athletic Federation auspices, are held in non-Olympic years. The women's pentathlon—shot-put, high jump, 200-m. dash, 80-m. hurdles, broad jump—was added to the program of the 1964 Olympic Games. *See* OLYMPIC GAMES. (E. J. G.)

PENTECOST (from Greek *pentekostos*, "50th"), the Jewish Feast of Weeks, or Shavuoth, celebrated on the 50th day after Passover. The name also is given to the Christian feast popularly called Whitsunday, celebrated on the 50th day after Easter to commemorate the descent of the Holy Spirit on the apostles. *See* JEWISH HOLIDAYS; WHITSUNDAY.

PENTECOSTAL CHURCHES. A group of religious bodies that emphasize holiness or Christian perfection as an experience climaxed by a spiritual endowment in which the recipient speaks in "unknown tongues" (*see* TONGUES, GIFT OF). The name and practices are derived from the phenomenon of the Day of Pentecost described in Acts 2:1–13.

Theologically, these churches belong to the ultraconservative or so-called fundamentalist school (*see* FUNDAMENTALISM). No definite creed is applicable to all the bodies, but their beliefs and practices follow a general pattern. Holiness is a work of grace subsequent to justification or conversion, the gift of tongues being a still higher experience. An intense premillenarianism and expectancy of the imminent Second Coming of Christ is usually present (*see* MILLENNIUM) based on the theory of the verbal inspiration of the Bible and the literal interpretation of the apocalyptic passages. Divine healing is frequently practised. Glossolalia, or speaking in tongues, is the characteristic feature, accompanied by a strong emotional element which induces motor automatisms and sometimes runs to wild and bizarre practices. In other aspects the Pentecostals do not greatly differ from other fundamentalist groups. Most of them have two sacraments, baptism (usually by immersion) and the Lord's Supper (often accompanied by foot washing). Among numerous small Negro Pentecostal churches are several "Jesus Only" sects, which reject the doctrine of the Trinity and baptize only in the name of Jesus; and a parallel group of "Father Only" cults, which baptize only in the name of the Father.

Many bodies, such as the Latter-day Saints, Foursquare Gospel adherents, and numerous small Negro sects, that inculcate the charismatic principle, including the gift of tongues, are not usually classed among the Pentecostal churches.

Pentecostal denominations are widespread throughout the United States and are found in many other countries. Forty or more identifiable groups in America practise glossolalia; in addition, there are hundreds of obscure "storefront" congregations that cannot be included in any reliable computation. Pentecostal churches abound also in remote mountain and other rural areas, and it is mainly among these that the pronounced emotional manifestations are found. The larger bodies are organized in the Pentecostal World Conference, an international fellowship which has headquarters in the United States and publishes in England a periodical called *Pentecost*.

Most of the Pentecostal churches, properly so-called, in America trace their origin directly or indirectly to the "Latter Rain" revival movement led by A. J. Tomlinson, founder of the Church of God, who promoted the revival so vigorously that it spread throughout the country during the first quarter of the 20th century. Schisms began to occur in 1917, and in a few years the movement split into numerous groups while many independent bodies were set up. The divisions were due mainly to the strong individualism of the doctrines preached, to the independence of the local congregations, to the rivalry of various leaders for power, and to Tomlinson's insistence on the exercise of total authority. There were several splits during his lifetime, and after his death misunderstanding between his two sons and the leaders of the Cleveland (Tenn.) church brought about further schisms. Four large Tomlinson sects survive. Other bodies indirectly derived from the Latter Rain revival are the Assemblies of God (*q.v.*); United Pentecostal Church, Inc.; Pentecostal Holiness Church; International Pentecostal Assemblies; Pentecostal Church of God; Calvary Pentecostal Church, Inc.; and Pentecostal Fire-Baptized Holiness Church. There are a dozen smaller churches in North America and several elsewhere. The revival flourished among the Italian communities in New York and Chicago and the resultant churches were federated in the Italian Pentecostal Assemblies of God and the Unorganized Italian Christian Churches of North America. *See* also GOD, CHURCHES OF; GOD IN CHRIST, CHURCH OF.

PENTELIKON (ancient Greek BRILESSOS or BRILETTOS, later called PENTELIKON after the village Pentele; Latin PENTELICUS; modern Greek PENDELIKÓN), a mountain in Attica, Greece, about 10 mi. (16 km.) NE of Athens, height 3,638 ft. (1,109 m.), famous for its white marble. This was not regularly worked until late in the 6th century B.C.; later all the chief buildings and sculptures of Athens were made of it. The ancient quarries (still visible) are mostly on the south side; the modern quarries on this and the north side. There was a sanctuary of Athena at the summit.

PENTLANDITE, a sulfide of nickel and iron, is the chief source of nickel. It is abundant in the nickel mines of Canada, as in the Sudbury district of Ontario where the mineral has an average nickel content of 35%. It also occurs in Norway, Sweden, and South Africa; in the United States it is found in Nevada and Yakobi Island, Alaska. It was named after J. B. Pentland who first noted the mineral. The formula is (Fe, Ni)S. It crystallizes in the cubic system but is never found in distinct crystals. It has a metallic lustre and light bronze-yellow colour. It is nearly always associated with pyrrhotite. For production and uses *see* NICKEL. (W. F. FG.; X.)

PENUMBRA (Lat. *paene,* "almost," *umbra,* a "shadow"), in astronomy, the partial shadow of a heavenly body as cast by the sun. It is defined by the region in which the light of the sun is partially but not wholly cut off through the interception of a dark body. *See* also ECLIPSE.

PENUTIAN, a superfamily of. North American Indian languages defined by the linguist E. Sapir as extending originally from British Columbia to Mexico. The families and languages are, from north to south: Tsimshian; Chinook (including Wishram); Sahaptian (Sahaptin, including Nez Perce, Yakima; Molala-Cayuse; Klamath); Oregon Penutian (Coastal: Alsea, Siuslaw, Coos; Kalapuya; Takelma); Californian (Wintun, Maidu, Miwok-Costanoan, Yokuts); Mexican Penutian (Zoque, Huave). Penutian is part of a larger grouping (phylum), Macro-Penutian, which includes Azteco-Tanoan (Uto-Aztecan, Kiowa-Tanoan), and, perhaps, Mayan and Totonac in Mexico. The relationships have not been worked out in detail, but all except the last two may be considered valid. Zuñi has been shown to be remotely related to California Penutian. About 5,000 speakers of Penutian remained in the 1960s, with some of the languages extinct.

Penutian languages have structures reminiscent of Indo-European—inflectional suffixes, internal stem-change, noun cases—with much variation. *See* also CENTRAL AND NORTH AMERICAN LANGUAGES; AMERICAN ABORIGINAL LANGUAGES; INDIAN, NORTH AMERICAN. (G. L. T.)

PENZA *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., formed in 1939, lies southeast of Moscow on the western flank of the Volga uplands. Area 16,680 sq.mi. (43,201 sq.km.). Pop. (1959) 1,509,566. From a maximum height of 1,089 ft. (332 m.) in the east its rolling interfluves drop gently to the Oka-Don plain in the extreme west. The north and east drain to the Volga by the Sura, the west to the Oka by the Moksha and its tributaries and the south to the Don by the Khoper and Vorona. The climate is continental: January average temperature is −13° C to −11° C (8°–11° F), July average about 20° C (68°) and rainfall moderate, 16 to 20 in. annually. The *oblast* lies in the zone of forest-steppe and about one-fifth of the surface is in pine or oak forest, mostly in the Sura Basin. In forested or formerly forested areas are leached chernozems or gray forest earths; in the steppe areas are chernozem (black earth) soils. Natural vegetation has been widely removed for agriculture, and subsequent soil erosion has been severe.

Of the 1959 population 499,384 (33%) were urban, living in 11 towns and 13 urban districts. Apart from Penza (255,481) and Kuznetsk (56,880), the urban centres are all small. Agriculture, the occupation of the majority of the working population, is overwhelmingly dominated by grain growing, especially by winter rye. Oats, fodder maize (corn), millet, and wheat are also grown. Industrial crops (chiefly sunflowers, hemp, and potatoes) are less important, while livestock farming is underdeveloped. Engineering, the main industry, is concentrated in Penza and Kuznetsk, other towns being mainly concerned with processing food and agricultural products, flax retting, and making woolen textiles, leather goods, and footwear. Timber working is important in the surviving forest areas, and paper is made. (R. A. F.)

PENZA, a town and administrative centre of Penza *oblast* in the Russian Soviet Federated Socialist Republic, U.S.S.R., lies 441 mi. (710 km.) SE of Moscow at the confluence of the Penza and Sura rivers. Pop. (1959) 255,481. The town had its origin in 1666 as a strongpoint at the western end of the Syzran defensive line, although a fort was founded there earlier by Ivan IV (the Terrible; 1530–84). With the settlement of the surrounding chernozem (black earth) lands, Penza became an important agricultural centre. Grain was sent to Moscow first by the Sura River and, after the 1870s, by rail. The processing of farm products is still one of the significant industries of Penza, but it has been surpassed in importance by engineering. Textile and chemical machinery, diesel engines, compressors, calculating machines, and bicycles are made; there are also watch making, paper making, and timber working. Penza has pedagogic and industrial institutes. That part of the town lying on the right bank of the Sura was formed into the separate satellite town of Zarechny in 1958. (R. A. F.)

PENZANCE, a municipal borough, seaport, and holiday resort, in the St. Ives parliamentary division of Cornwall, 280 mi. (451 km.) WSW of London by road and the most westerly town in England. Pop. (1961) 19,281. After 1934 the borough included Newlyn, Mousehole, Gulval, and Heamoor. It is the only quarter sessions borough in Cornwall.

The town stands on rising ground overlooking Mounts Bay, and has a remarkably equable climate, enabling many subtropical plants to flourish in the open air. Great quantities of early vegetables, flowers, and fruits are raised locally and in the Scilly Isles (*q.v.*), and are sent to London and elsewhere. Penzance is connected with the Scilly Isles by steamer and air services. Some fishing is done from Penzance Harbour, but most of the fishing boats work from Newlyn Harbour. From the mean sea level in Newlyn Harbour—ordnance datum—is calculated the elevation of all places shown on ordnance survey maps. Newlyn is a well-known centre for artists.

Edward III granted Penzance a charter market in 1332. In 1512 Henry VIII granted a charter as to profits from all ships visiting the harbour, although the town's importance as a fishing port dates from the 14th century. The charter of incorporation was granted in 1614 and in 1663 Penzance was constituted a coinage town for tin, and so remained until 1838. The old name (Pensans) is thought to have referred to a chapel of St. Anthony (patron saint of fishermen) formerly on the headland south of the harbour. The seal and coat of arms granted by the College of Heralds in 1934 to replace the old corporate seal, however, make a very free translation of the name and depict the head of St. John the Baptist on a charger.

PEONAGE, a form of involuntary servitude. The beginning of peonage has been traced as far back as the conquest of Mexico by the Spaniards. Early in the history of Mexico the conquerors worked out a plan by which the poor, especially the Indians, could be forced to do the work of the planters and mine operators. The word *peon* became synonymous with the English word labourer, but it later was restricted in its meaning to those labourers who were compelled to serve their creditors to pay debts which by contract they had pledged themselves to pay in labour.

Although the 13th Amendment and congressional legislation prohibited any such involuntary servitude in the United States, the former slave-holding states devised certain legislation, following emancipation, to make labour compulsory. Under these state laws employers deceived ignorant men by inducing them to sign contracts for labour in payment of debts, and those who might have to pay fines imposed by the courts to sign other similar contracts. In rural districts far removed from the populous centres the chain-gang system of forced labour under the pretense of farming out the services of penal offenders resulted in great injustice. The practice of leasing short-term prisoners, both white and Negro, to managers of labour camps was continued in a few of the southern states. (C. G. W.)

PEONY (PAEONY), common name for *Paeonia,* a genus of plants remarkable for their large and showy flowers; it belongs to the buttercup family (Ranunculaceae). The peonies are native mostly to Europe and Asia; one species, *P. brownii* (the western peony), is found naturally along the Pacific coastal mountains in North America.

Known from ancient times, and called *paeonia* by the Greeks, after Paean (*q.v.*), a physician of the gods, the peony was regarded with the greatest respect. As late as the 17th century its

roots, flowers, and seeds were used in medicine in England. In China and Japan it has been grown for ages and esteemed for its beauty and fragrance. The Mongols in Siberia were reported, in the 18th century, to have eaten the roots and seeds of the peony.

There are two distinct general groups of peonies: the herbaceous and the tree or moutan peonies. The herbaceous are strong-growing perennials from two to three feet in height; the large, glossy, much-divided leaves, decorative from spring to fall, are supported on annual stems, which arise from the fleshy rootstock.

ROCHE

JAPANESE DOUBLE TREE PEONY (HORTICULTURAL VARIANT OF PAEONIA SUFFRUTICOSA)

The ample flowers, which blossom in late spring and early summer, when few flowers equal them in effect, vary in form from the open single to the globular sorts of the double varieties. The Chinese *Paeonia lactiflora* (or *P. albiflora*) and the European *P. officinalis* (the common peony—an old garden favourite), along with their many horticultural varieties, are the herbaceous garden peonies which produce the large single and double flowers of white, pink, rose, and deep crimson. Modern garden hybrids are quite beautiful, the flowers being in many instances delicately tinted with more than one colour, such as buff with bronzy centre, carmine with yellowish centre, rose with orange centre, white tinted with rose, etc. Hundreds of names are given to the colour variations of both the herbaceous and tree peonies.

The tree peonies, sometimes known as moutan peonies, have sprung from the wild Chinese species *P. suffruticosa*. They are stiff-growing plants with woody permanent stems. They are remarkable for their shrubby habit, forming vigorous plants sometimes attaining a height of four to six feet, and producing in late spring magnificent flowers which vary in colour from white to lilac, magenta, violet, rose, and red. These are produced on the young shoots and are in consequence liable, unless protected, to be cut off by spring frosts. Tree peonies require a thorough ripening in summer, and therefore a hot, dry season is desirable for their well-being. They can be increased by grafting in late summer or autumn on the roots of herbaceous peonies. A race of hybrids developed by crossing the tree peony with the yellow Chinese species *P. lutea* has both single and double flowers sometimes tinged with red. A variety of *P. lutea*, discovered in south-western Tibet in 1936 and named *P.* var. *Ludlowii*, bears magnificent large butter-yellow flowers on stems about six feet high. It is the earliest of the large tree peonies to flower in England, where it is perfectly hardy.

All peonies thrive in rich, moist but well-drained garden loam in a sunny location, planted—preferably in the spring—so that the buds or "eyes" of the fleshy roots are not more than three inches deep. They are not commonly grown from seed, which take about two years to germinate. After about a year they become well established and will produce blooms for years without the necessity of dividing.

An annual top-dressing of bonemeal or rotted manure is beneficial since peonies are heavy feeders; tree peonies benefit by a dressing of old leaves alone.

Stern, *A Study of the Genus Paeonia* (1946); "Tree Peonies," *Journal of the Royal Horticultural Society*, 78:214 (1953); *Handbook of the American Peony Society* (1953); J. C. Wister (ed.), *The Peonies* (1962). (FR. S.)

PEORIA, a city of north-central Illinois, U.S., on the Illinois River where it widens to form Lake Peoria, roughly midway between Chicago and St. Louis, Mo., is a leading commercial centre of downstate Illinois and the seat of Peoria County.

Named for one of the five Indian tribes in the Illinois confederacy, Peoria represents one of the oldest settled locations in the state. The French under René Robert Cavelier, sieur de La Salle (*q.v.*), first built Ft. Crèvecoeur on the bluffs opposite the present city in 1680, but it was plundered and deserted later that same year. Subsequent settlements around Lake Peoria by the French, Indians, and Americans give an almost unbroken history to the region. After 1813 the location was known as Ft. Clark and when Peoria County was established in 1825, the community reverted to the French-Indian name of Peoria and was established as the county seat. Peoria was incorporated as a town in 1835 and chartered as a city in 1845. It was there, on Oct. 16, 1854, that Abraham Lincoln publicly denounced slavery in a rebuttal to a speech by Stephen Douglas.

Peoria is situated in the heart of the corn belt, with deposits of bituminous coal, sand, gravel, and gypsum nearby. It has excellent rail, road and air transport facilities including the Illinois waterway. The city's industry is both vast and varied. Producing more than 900 different products in more than 200 manufacturing plants, Peoria is as well known for its tractors, agricultural implements, and earth-moving equipment as it is for products of its numerous distilleries and breweries. The output of chemicals, food products, household goods, brick, tile and stone, radio equipment, and electric power is also extensive. The U.S. Department of Agriculture Northern Regional Research Laboratory, which searches for new and improved uses for farm commodities, is located there.

The city, extending for more than 10 mi. (16 km.) along the Illinois River, is noted for its setting amid the scenic beauty of the surrounding area. Six public parks totaling more than 2,000 ac. (809 ha.) offer opportunities for relaxation and recreation. Bradley University, located near the west edge of the city, was established by Lydia Bradley in 1897 and endowed by her with a gift of $2,000,000.

Population (1960) 103,162; standard metropolitan statistical area (Peoria and Tazewell counties), 288,833, to which Woodford county (pop. [1960] 24,579) was added in 1963. For comparative population figures *see* table in ILLINOIS: *Population*.

(R. M. SU.)

PEPE, GUGLIELMO (1783–1855), Neapolitan general prominent in the Italian *Risorgimento*, was born at Squillace in Calabria on Feb. 13, 1783. He attended a military academy at Naples before joining the army of the Parthenopean Republic (*see* NAPLES, KINGDOM OF) in 1799. Fighting against the Royalists, he was wounded and captured, but his life was spared because of his youth. Banished by the restored Bourbons, he made his way to France and joined the "Italian Legion" of exiled patriots at Dijon. He went back to Italy with Napoleon to fight at Marengo (1800) and later took part in operations against the anti-French brigands of central Italy. On a subversive mission to Naples, he was arrested and imprisoned. Set free when Joseph Bonaparte became king of Naples (1806), he resumed his army service. Having commanded a brigade in Spain (1811–13), he fought for Joachim Murat in 1814 and 1815.

Under the Bourbon kingdom of the Two Sicilies, Pepe served from 1818 against brigands in Calabria. This brought him into contact with the Carbonari (*q.v.*); and when revolution broke out in 1820, Pepe was made commander in chief of the army by the constitutionalists. Internal quarrels weakened the regime, and Pepe could not prevent the defeat at Rieti (March 1821) and the overthrow of the constitutional government. He went into exile, living mainly in England, writing on Italian affairs and keeping in touch with revolutionaries in Italy.

In 1848 Pepe returned to Naples after the revolution, was reinstated in the army and put in command of the force sent north against the Austrians (*see* ITALIAN INDEPENDENCE, WARS OF). The expedition was soon recalled, but Pepe refused to obey this order and crossed the Po with some of his troops to fight in the Veneto. Entering Venice (June 1848), he was made commander of the garrison and cooperated with Daniele Manin in defense of the city. The wisdom of his conduct there has been debated. When Venice surrendered (Aug. 1849), he went to Paris. After Louis Napoleon's *coup d'état* (1851), Pepe moved to Turin, where he died on Aug. 8, 1855. Pepe's publications in English include *Narrative of the Political and Military Events . . . at Naples in 1820 and 1821* (1821), *Memoirs of General Pepe* (1846), and

Narrative of Scenes and Events in Italy from 1847 to 1849, two volumes (1850).

PEPERINO, an Italian name applied to a brown or gray volcanic tuff (*q.v.*), formed from volcanic ash or dust and containing fragments of basalt and limestone, with disseminated crystals of augite, mica, magnetite, leucite, etc. The typical peperino occurs in the Alban Hills, near Rome, and was used by the ancients, under the name *lapis albanus,* as a building stone and for the basins of fountains. Other tuffs and conglomerates in Auvergne and elsewhere are also called peperino. The name originally referred to the dark-coloured inclusions, suggestive of peppercorns. *See* also ROME: *The Ancient City: Materials.*

PEPIN (PIPPIN), the name of several members of the Carolingian dynasty.

PEPIN I (d. *c.* 640), called Pepin the Old or Pepin of Landen (after one of his estates near Trier), was a councilor of the Merovingian king Clotaire II and mayor of the palace in Austrasia. Through the marriage of his daughter Begga with Ansegisel, son of Arnulf (d. 641; bishop of Metz), Pepin was the founder of the Carolingian dynasty. Deprived of his mayoralty at the accession (629) of Dagobert I, he regained power in Austrasia after that king's death (January 639) but did not long survive to enjoy it.

PEPIN II (d. 714), called Pepin the Young, or sometimes Pepin of Herstal or Heristal, son of Begga and Ansegisel, escaped the massacre of his family which the ambition of his uncle Grimoald provoked in 662. After the death in 679 of Dagobert II of Austrasia, however, Pepin established himself as mayor of the palace in that kingdom and defended Austrasian autonomy against Thierry III of Neustria and Ebroïn, Thierry's mayor of the palace. Defeated by Ebroïn in 680 at Lucofao (Bois-du-Fay, near Laon), Pepin gained his revenge in 687 at Tertry (near Péronne) and became sole effective ruler of all the Merovingian territory. He nevertheless maintained Thierry III on the throne and after his death replaced him with three successive Merovingian kings. For Neustria and Burgundy, he delegated the functions of mayor first to one of his adherents, Norbert, then (*c.* 700) to his own son Grimoald.

Pepin, after several years of warfare, defeated the Frisians on his northeastern border (689) and married his son Grimoald to Theodelind, daughter of the Frisian chief Radbod. He also asserted himself over the Alamanni and encouraged Christian missionaries in Bavaria. He died at Jupille, near Liège, on Dec. 16, 714.

PEPIN III (d. 768), called Pepin the Short, was the younger of the two sons between whom Charles Martel (*q.v.*) divided his succession in 741. Pepin and his brother Carloman at first perpetuated the fiction of Merovingian sovereignty, placing Childeric III on the throne in 743. Carloman, however, retired to a monastery in 747, leaving Pepin in sole control of the kingdom; and about four or five years later Pope Zacharias agreed to the deposition of Childeric from the kingship in Pepin's favour. Pepin was then anointed, perhaps, as is often said, by St. Boniface, at Soissons between Oct. 31, 751, and Jan. 23, 752. This ceremony, new in Gaul, recalled Biblical traditions and the unction of the Visigothic kings of Spain. With his two sons, Charles and Carloman, Pepin was again anointed in July 754 by Pope Stephen II (III), who had come to seek his help against the Lombards in Northern Italy. In pursuance of his agreement with the pope, Pepin took an army to Lombardy in 754 and in 756, in an attempt to make the Lombard king Aistulf restore to Rome territory which the pope assumed had originally been ceded by Constantine to the bishop of Rome (*see* DONATION OF CONSTANTINE). In 763 Pepin acted as a mediator between the new Lombard king, Desiderius, and Pope Paul I.

Meanwhile, Pepin had much to do to keep his own territory in order and to repel hostile neighbours. He drove the Muslims from Septimania, but was continually threatened by the Frisians and by the Saxons, who repeatedly devastated the Rhineland area. Over Duke Tassilo III of Bavaria his authority was very uncertain: though Tassilo helped Pepin against the Lombards in 756, he withdrew his troops from Aquitaine in the middle of Pepin's campaign of 763 and thereafter acted quite independently. Aquitaine itself caused endless trouble: between 760 and 768 there were only two years during which Pepin was not at war in this region. Pepin died at Saint-Denis, on his way back from one of his Aquitanian expeditions, on Sept. 24, 768.

From the earliest years of his reign Pepin had carried out administrative, ecclesiastical, and legal reforms, and his numerous capitularies were to form the basis of Charlemagne's work.

PEPIN (d. 810), king of Italy, the second son of Charlemagne, was given the title of king of Italy in 781. He took part in campaigns against Tassilo III of Bavaria from 787 and led an army against the Avars in 796. His Venetian campaign (809–810) enabled Charlemagne later to treat with Byzantium on favourable terms. As early as 806 Charlemagne, in planning the division of his lands, had determined that when he himself died Pepin should have Italy, Bavaria, and the territory of the Alamanni together as a kingdom. But Pepin predeceased his father, dying on July 8, 810.

PEPIN I of Aquitaine (d. 838), second son of the emperor Louis I the Pious, was granted Aquitaine in July 814 and was recognized as king in 817, although it was clear that he was to remain subordinate to his elder brother Lothair, the heir to the imperial title. It was Pepin who in 830 started the revolt of Louis I's elder three sons against their father, but in February 831 he became reconciled with Louis. Rebelling again in 832, he was then deposed from his kingship by Louis, but could still exploit separatist feeling in Aquitaine and took part in renewed rebellion against Louis in 833. He finally repented in 834 and helped to restore the emperor's authority. Aquitaine was then given back to him, with Anjou in addition. He died, probably insane, on Dec. 13, 838.

PEPIN II of Aquitaine (d. after 864) was the son of Pepin I. When, in 839, the emperor Louis I granted Aquitaine to his youngest son Charles the Bald (*see* CHARLES II, emperor), a strong party in the kingdom repudiated Charles and proclaimed Pepin as king. In the war between Charles and his half-brothers after Louis I's death (840), Pepin supported his eldest uncle, Lothair, who found him a useful ally in Charles's rear; and after the Treaty of Verdun (843), which made no provision for him, he fought on alone against Charles. He won a victory in Angoumois on June 14, 844; and about a year later, at Saint-Benoît-sur-Loire, Charles received his homage and appointed him to rule in Aquitaine.

War soon broke out again, and Charles occupied Aquitaine step by step. Having taken refuge with Sancho, duke of the Gascons, Pepin was handed over to Charles in September 852. He was then tonsured and relegated to the monastery of Saint-Médard at Soissons. Escaping in 854, he renewed the struggle, but in 859 the Aquitanians began to abandon his cause. Thereafter he became a wanderer, sometimes joining Viking raiders, with a band of whom he attacked Toulouse in 864. Captured soon afterward, he was imprisoned at Senlis, where he died.

(J. DE.)

PEPOLI, an Italian family, important especially in the history of Bologna. They first became prominent during the 13th century as merchant bankers of great wealth. They were Guelphs, and it was as leader of the Guelphs that ROMEO PEPOLI came near to obtaining lordship of Bologna early in the 14th century. He was stopped by a factious rising and died in exile in 1321. His son TADDEO was more fortunate: with popular support he was granted lordly power, with the title "conservator of peace and justice," in 1337; and later Pope Benedict XII confirmed his authority by appointing him vicar. His sons GIACOMO and GIOVANNI succeeded him on his death in 1347, but their rule was short: faced by the superior power of Giovanni Visconti, lord of Milan, they sold him the city in 1350. The government of Bologna underwent many revolutions in the following 100 years, but never again did the Pepoli manage to obtain power. They kept their wealth and land,

however, and a permanent place among the aristocracy of Bologna, the Papal States, and also southern Italy. Most notable, perhaps, among the soldiers, statesmen, and writers of the family were the conte CARLO (1796–1881) and the marchese GIOACCHINO NAPOLEONE PEPOLI (1825–81), both of whom played an active part in the Risorgimento. Gioacchino Napoleone, who belonged to the southern branch of the family, held public offices after the unification of Italy.

PEPPER is a name applied to several unrelated plants from which pungent spices are obtained: black, white, and long pepper (*Piper*); red, chili, and cayenne peppers (*Capsicum*) and Melegueta pepper (*Aframomum melegueta*). Pepperroot (*Dentaria*) whose underground parts and peppergrass (*Lepidium*) whose fruits have a pungent taste are members of the mustard family. A number of plants named pepper, including the California pepper tree (*Schinus molle*), pepper vine (*Ampelopsis arborea*), and sweet pepper bush (*Clethra alnifolia*), are grown as ornamentals and are not used for spices.

Black Pepper.—The true pepper or black pepper (*Piper nigrum*, family Piperaceae) is native to northwest India, and in early historic times was widely cultivated in the tropics of southeastern Asia, where it became highly regarded as a condiment. Marco Polo in the 13th century observed great quantities of peppers being used in China and noted that their cultivation extended as far as Java. Pepper early became an important item of overland trade between India and Europe. It became a medium of exchange, and tributes were levied in pepper in Greece and Rome. The Venetians and Genoese were two of the chief distributors, and their virtual monopoly of the trade helped instigate the search for a sea route to the Far East.

H. HODGE

FRUITING BRANCH OF A BLACK PEPPER TREE (PIPER NIGRUM)

The pepper plant is a woody climber that by means of aerial roots reaches heights of 30 ft. or more. The shiny green leaves are broad, ovate, and alternately arranged. The inconspicuous flowers, which lack a perianth, are arranged in dense slender spikes of about 50 flowers each. The fruit, called a peppercorn, a small globose berrylike structure, ⅛–¼ in. in diameter, becomes yellowish red at maturity, and bears a single seed. A number of cultivated varieties are known.

The plant requires a long rainy season, fairly high temperatures, and partial shade to produce its best growth. Propagation is generally by stem cuttings, which are set out near a tree, or a pole that will serve as a support. The plants are sometimes interplanted in tea or coffee plantations. Peppers start bearing in two to five years and under good conditions may produce for 40 years or more. Harvesting is done by hand just before the fruits ripen. The peppercorns are spread out to dry in the sun, or occasionally over fires. In a few days the green fruits turn black and are ready for shipment. When ground, the whole peppercorn yields black pepper. For the preparation of white pepper, which has a milder flavour, the outer hull and pulp are first removed from the seed by fermentation in water. White pepper also is prepared from the whole dried peppercorns, by grinding off the outer coating.

Pepper owes its pungency to a resin and its flavour to a volatile oil. Piperine, an alkaloid with the same empirical formula as morphine, also is present. It is probably the world's most widely used spice and also has a limited usage in medicine.

The pepper is rather widely cultivated in India, Thailand, the East Indies, and islands of the South Seas, with Indonesia producing the bulk of the world's supply. The plant has been successfully introduced into tropical areas of Africa and of the Western Hemisphere. World exports have amounted to 170,000,000 lb. a year, with U.S. imports reaching 50,000,000 lb. a year.

Long pepper, whose culture and preparation is similar to that of black pepper, is prepared from *Piper retrofractum*, native to Java, and *Piper longum*, native to India. Although it was popular in Europe during the Middle Ages, it is little used today outside the areas where it is grown. Of the 600 to 700 species of *Piper*, a few others are of economic importance. Cubebs from *Piper cubeba*, native to the East Indies and cultivated in the Far East, formerly were used as a spice or condiment and now have a limited use in medicine for the treatment of catarrh. The roots of *Piper methysticum* are used throughout Oceania to produce the beverage kavakava. The leaves of the betel pepper (*Piper betle*) are chewed with the nuts of the betel palm in much of the tropics of the Old World as a masticatory. (C. B. H.)

Fleshy Peppers.—The genus *Capsicum*, of the nightshade family (Solanaceae; *q.v.*), comprises all the varied forms of fleshy-fruited peppers grown as herbaceous annuals—the green, red, and yellow peppers used in seasoning and as a vegetable food. The edible fruit, a podlike, many-seeded berry with a thick rind, is variously shaped and coloured. All garden peppers are derived from *C. frutescens* (incorporating *C. annuum* and *C. baccatum*), a tropical woody shrub up to eight feet tall, apparently a native of Central and South America. Most authors consider them varieties of the single species. The cultivated peppers used as spices and condiments include the pungent cherry (*cerasiforme*); cone, Tabasco, and coral gem (*conoides*); red cluster (*fasciculatum*); and long "hot" chili and cayenne (*longum*), often called capsicums. The mild bell or sweet peppers (*grossum*) have larger, variously coloured but generally bell-shaped, furrowed, puffy fruits that are used in salads and in cooked dishes. The term "pimiento," from the Spanish for "pepper," is applied to certain mild pepper varieties possessing distinctive flavour but lacking pungency; these include the European paprikas, which provide the paprika of commerce, a powdered red condiment. ("Pimiento," pronounced the same as "pimento," should not be confused with the latter, which is allspice; *q.v.*). The powdered red pepper of commerce is made from dried capsicums. An active principle obtained from capsicums is used as a counterirritant in medicine and to add pungency to ginger ale.

Pepper plants are treated as tender summer annuals outside their native habitat. Cultivation is the same as for their relative, the tomato (*q.v.*): seeds are sown under glass and the plantlets are set out when weather permits.

See Howard Scott Gentry, "Introducing Black Pepper into America," *Econ. Bot.*, vol. ix, pp. 256–268 (1955); Albert F. Hill, *Economic Botany* (1952).

PEPPERGRASS, a name given, especially in the United States, to certain species of *Lepidium* (family Cruciferae), which are widely spread as weeds. They are erect, mostly annual herbs with freely branching stems, about one-half to one and one-half feet high, small, toothed or deeply cut leaves, minute white or yellow flowers, followed by elongated, cylindrical clusters of small, short-stalked, flattened, nearly round, two-seeded, slightly notched pods. Examples are the wild peppergrass (*L. virginicum*), with mostly undivided leaves, found in fields from Quebec to Minnesota and southward to Mexico and the West Indies, and also naturalized in southern Europe, and the roadside peppergrass (*L. ruderale*), with narrowly divided leaves, native to Europe but now naturalized from Nova Scotia to Texas, and occurring also in Australia.

PEPPERMINT, a strongly aromatic perennial herb furnishing the well-known flavouring of wide use. It is one of many species of *Mentha—M. piperita*—distinguished from others of the genus by its stalked leaves and oblong-obtuse spikelike heads of flowers. It is native to Europe and has become naturalized in North America, found near streams and other wet sites. In several parts of the world, including Europe, Asia, and North America, it is cultivated

for its essential oil. Many varieties of peppermint have resulted from natural hybridization among wild species; but only two varieties, the black and white, are recognized by growers. The former has purplish and the latter green stems; the leaves are more deeply toothed in the white. Black peppermint (also known as English peppermint and mitcham mint) is the form extensively grown in the United States, probably because it is found to yield more oil. The white variety is less hardy and less productive but its oil is considered more delicate in odour and obtains a higher price.

U.S. DEPARTMENT OF AGRICULTURE
PEPPERMINT (MENTHA PIPERITA)

After about 1900 the United States became an important producer of peppermint oil. Production on a large commercial scale was first attained in southern Michigan and was later extended to northern Indiana. Shortly after World War II, the states of Washington and Oregon became important centres of peppermint culture because of climatic factors, including long summer days with abundant sunshine, which favour the production of high yields of oil. In the beginning of the second half of the 20th century, the United States was the leading peppermint-producing country, with production of over 2,000,000 lb. accounting for nearly three-fourths of the world's supply of peppermint oil. Bulgaria, Italy, the U.S.S.R., France, and other countries in Europe and Asia also produce the oil. Peppermint can be grown on a wide range of soil types but does best in deep, rich soils well supplied with moisture from rainfall or irrigation. In the United States it is produced on muck soils in Michigan and Indiana and sandy-loam soils in Oregon and Washington. Peppermint is propagated commercially by planting stolons (underground shoots) taken from existing fields. It is often grown in rows the first year and then allowed to spread over the field in solid stands spoken of as meadow mint. Fields may produce satisfactory crops for two to five years or longer if weeds and diseases are controlled. Best yields of oil are obtained when peppermint is harvested by cutting at the full-bloom stage.

Oil of peppermint is a volatile oil distilled with steam from the partially dried herb. It is widely used for flavouring dental creams, mouthwashes, toothpastes, cough drops, chewing gum, and confectionery, and to a lesser extent for masking the flavour and odour of numerous medicinal products. When pure, peppermint oil is nearly colourless and has an agreeable odour and a powerful aromatic taste, followed by a sensation of cold when air is drawn into the mouth. When oil of peppermint is cooled to 4° C it sometimes deposits colourless hexagonal prisms of menthol, which are soluble in alcohol and ether, almost insoluble in water, and fusible at 92° F; the oil consists chiefly of menthol and a ketone called menthone. Oil of peppermint is sometimes adulterated with phellandrene or other terpene compounds, water soluble glycols, or synthetic menthol. Adulteration with terpenes or glycols can be detected readily by using appropriate chemical or physical tests, but no satisfactory method has been found for proving adulteration with synthetic menthol. Oil of Japanese mint (*M. arvensis* var. *piperascens*) is a rich source of menthol, very different from peppermint oil. The name Japanese peppermint is sometimes used for this plant, but it should not be confused with true peppermint.

See E. Guenther, *The Essential Oils*, vol. 3, pp. 586–640 (1949); J. W. Parry, *Spices*, pp. 132–135 (1962). (L. M. Pz.)

PEPPERRELL, SIR WILLIAM (1696–1759), American merchant, colonial leader, and soldier who captured Louisburg in 1745, was born in Kittery, Me. (then a part of Massachusetts), on June 27, 1696, the son of Col. William Pepperrell. He studied navigation and surveying, both valuable in his later life as merchant and landlord and as an associate of his father in one of the most respected mercantile firms in colonial America. The Pepperrells were not so phenomenally successful or as daringly speculative as many American merchants, but over a period of 75 years they amassed considerable wealth. They prospered from New England's two major resources, lumber and fish, and from the flexibility of their trading policies, careful selection of business agents, maintenance of a reputation for honesty and integrity, and investments in real estate.

With success came a position of importance in New England society and politics. Pepperrell married the daughter of a wealthy merchant, Grove Hirst, and took an active interest in public affairs. He served at various times as a member of the Massachusetts General Court and the Governor's Council, as acting governor of Massachusetts, and as chief justice of the Court of Common Pleas. He succeeded his father as colonel of the Maine militia and, because of his military experience and his familiarity with the eastern frontier and with Indian affairs, he was selected by Gov. William Shirley to command the land forces in the siege of Louisburg in 1745 during King George's War. His success in this expedition resulted in his being created a baronet. For his service in raising troops during the French and Indian War he was given the rank of lieutenant general in the British Army. He died in Kittery, July 6, 1759.

See Byron Fairchild, *Messrs. William Pepperrell: Merchants at Piscataqua* (1954). (Ra. Mu.)

PEPPER TREE, a tree which has no proper connection with the true pepper (*Piper*), and is really a member of the family Anacardiaceae, being known botanically as *Schinus molle*, from the Peruvian name *Molle*. It is a native of tropical South America and is grown in the open air in the south of Europe. Introduced into California, it became widely popular as an ornamental tree, but later it was found to be a host plant for scale insects very destructive to orange orchards, with the result that in citrus districts the trees were cut down and further plantings discouraged. It is a small tree with unequally pinnate leaves, filled with volatile oil stored in large cells or cysts which are visible to the naked eye and appear like holes when the leaf is held up to the light. When the leaves are thrown upon the surface of water the resinous or oily fluid escapes with such force as to agitate them violently. The flowers are small, whitish, arranged in terminal clusters, and polygamous or unisexual, with five sepals, as many petals, ten stamens (as large as the petals in the case of the male flower, very small in the female flower, but in both springing from a cushionlike disk surrounding the base of the three-celled ovary).

The fruit is a small, globose, pealike drupe with a bony kernel enclosing a single seed; its fleshy portion has a hot aromatic flavour from the abundance of the resin it contains. The resin is used for medicinal purposes by the Peruvians, and has properties similar to mastic. The very similar Christmasberry tree (*S. terebinthifolia*), native to Brazil, with stiffer, less pendulous branches, more densely clustered flowers and smaller, bright red fruit, is sparingly planted for ornament. The Japan pepper tree is *Zanthoxylum piperitum* the fruits of which have also a hot taste. Along the Riviera the tree known as *Melia azedarach* or the "pride of India," is also incorrectly called the pepper tree.

PEPSIN is the powerful enzyme, or ferment, in gastric juice that digests proteinous foods such as meat, eggs, or seeds that are introduced into the stomach. Enzymes (*q.v.*), in general, are catalysts that in small quantities speed up biochemical reactions. They are formed by living tissues, and all cells are dependent upon them to speed up the many reactions that otherwise would proceed far too slowly.

Pepsin was first recognized in 1836 by the German physiologist Theodor Schwann. Nearly a century later, in 1930, it was crystallized and its protein nature established by John H. Northrop of the Rockefeller Institute for Medical Research.

The tissues lining the stomach make and store pepsin in an inactive form called pepsinogen, or propepsin. When pepsinogen is

secreted into the stomach and mixed with the acidic gastric juices, it is rapidly converted into pepsin. Pepsin speeds up this conversion, and since it is also a product of the conversion, the reaction once started goes faster and faster; *i.e.*, it is self-accelerating or autocatalytic. The digestive power of pepsin changes with acidity, and, as might be expected, it is fastest at the acidity of normal gastric juice (PH 1.5–2.5).

Proteins, in general, are made up of some 20 different kinds of amino acids linked together. Only the links between certain pairs of amino acids are opened by pepsin. In the digestive tract this leads to only partial degradation of proteins to smaller units called peptides, which are then either absorbed from the intestine into the bloodstream or are broken down further by pancreatic enzymes. The magnitude of the digestive power of pepsin may be indicated by pointing out that one ounce of pure pepsin can coagulate (an early step in the digestion) 200,000 gal. of milk in an hour at body temperature or can digest thousands of times its weight of other proteins in a similar period. Although pepsin is a protein, it is resistant to its own digestive powers.

Like other enzymes and proteins, pepsin is a large, complex molecule. On a weight scale in which an atom of hydrogen is 1 and ordinary table salt (sodium chloride) is 58, pepsin is 35,000.

Pepsin is prepared commercially from swine stomachs, which contain on the average about one gram (one-thirtieth of an ounce) of enzyme per stomach. Crude pepsin is used in the leather industry to remove hair and residual tissue from animal hides prior to their being tanned. It is also used in the recovery of silver from discarded movie films, which it does by digesting the gelatin layer that holds the silver compound. Still another commercial use is in the preparation of peptone (partially digested protein), which is an important ingredient of growth media for bacteria and related microorganisms.

See also DIGESTION: *Proteins;* PROTEINS.

BIBLIOGRAPHY.—The original papers describing most of the work of Northrop and his colleagues on pepsin appeared in the *J. Gen. Physiol.*, vol. 13–32 (1930–48). *See* also J. H. Northrop, M. Kunitz, and R. M. Herriott, *Crystalline Enzymes*, 2nd ed. (1948); J. B. Sumner and G. F. Somers, *Chemistry and Methods of Enzymes*, 3rd ed. (1953).

PEPUSCH, JOHN CHRISTOPHER (JOHANN CHRISTOPH) (1667–1752), Anglo-German musician, composer, theorist, and teacher, was born in Berlin in 1667 and settled in England about 1700. In 1712 he became music director to the duke of Chandos and not long after was appointed music director at Lincoln's Inn Fields Theatre. Among much other music for the theatre he arranged the tunes and composed the overture for John Gay's *Beggar's Opera* (1728) and its sequel *Polly* (unperformed till 1777). In 1737 he became organist of the Charterhouse and was in some demand as a teacher; William Boyce was among his pupils. He collected a magnificent library of music books and scores and was deeply interested in music of the Renaissance and that of ancient Greece and Rome. He had a strong influence on the early development of musical antiquarianism in England, which led to the publication of such collections as Boyce's *Cathedral Music* and to the performance of old music by societies of enthusiasts. He died in London on July 20, 1752.

With the exception of the overture to *The Beggar's Opera* and some chamber music, little of Pepusch's music is performed in modern times.

See C. W. Hughes, "J. C. Pepusch" in *The Musical Quarterly*, xxxi (1945).
(CS. CH.)

PEPYS, SAMUEL (1633–1703), English man of letters and naval administrator whose celebrated diary gives a valuable, entertaining, and intimate picture of the social life of his day, was born on Feb. 23, 1633, in Salisbury Court near St. Bride's Church, London. He was the son of a working tailor who had come to London from Huntingdonshire, in which county, and in Cambridgeshire, his family had lived for centuries as monastic reeves, rent collectors, farmers, and, more recently, small gentry. His mother, Margaret Kite, was the sister of a Whitechapel butcher. But, though of humble parentage, Pepys rose to be one of the most important men of his day, becoming England's earliest secretary of the Admiralty and serving in his time as member of

Parliament, president of the Royal Society (in which office he placed his *imprimatur* on the title page of England's greatest scientific work, Sir Isaac Newton's *Principia*), master of Trinity House and of the Clothworkers' Company, and a baron of the Cinque Ports. He was the trusted confidant both of Charles II, from whom he took down in shorthand the account of his escape after the Battle of Worcester, and of James II, whose will he witnessed before the royal flight in 1688. The friends of his old age included Sir Christopher Wren, Sir Isaac Newton, John Evelyn, Sir Godfrey Kneller, John Dryden, and almost every great scholar of the age.

Early Career.—Samuel Pepys (pronounced *Peeps*) was sent, after early schooling at Huntingdon, to St. Paul's School, London. In 1650 he was entered at Trinity Hall, Cambridge, but instead went as a sizar to Magdalene College, obtaining a scholarship on the foundation. In March 1654 he took his B.A. degree and in 1660 that of M.A. Little is known of his university career save that he was once admonished for being "scandalously overseene in drink." In later years he became a great benefactor of his college, to which he left his famous library of books and manuscripts. He was also once offered—but refused—the provostship of King's College, Cambridge.

In December 1655 he married a penniless beauty of 16, Elizabeth Marchant de St. Michel, daughter of a French Huguenot refugee. At this time he was employed as factotum in the Whitehall lodgings of his cousin, Adm. Edward Montagu, later 1st earl of Sandwich, who was high in the Lord Protector Cromwell's favour. In his diary Pepys recalls this humble beginning, when his young wife "used to make coal fires and wash my foul clothes with her own hand for me, poor wretch, in our little room at Lord Sandwich's, for which I ought ever to love and admire her and do." While there, on March 26, 1658, he was cut for the stone (a most perilous operation), thereafter always celebrating the anniversary of his escape by a dinner—"the day of my solemnity for my cutting of the stone."

In 1659 Pepys accompanied Montagu on a voyage to the Sound. About the same time he was appointed to a clerkship of £50 per annum in the office of George Downing, one of the tellers of the exchequer, after whom Downing Street was later named. It was while working in Downing's office and living in a small house in Axe Yard that on Jan. 1, 1660, he began his diary. A few months later he sailed, as his cousin's secretary, with the fleet that brought back Charles II from exile. Appointed, through Montagu's interest at court, clerk of the acts of the navy at a salary of £300 per annum, and given an official residence in the navy office in Seething Lane, he became in the next few years a justice of the peace, a commissioner for, and later, treasurer of, Tangier, and surveyor of naval victualling. When he entered upon his functions, he was ignorant of almost everything that belonged to them. His chief use of his position was to enjoy his newfound importance and the convivial companionship of his colleagues, Admirals Sir William Batten and Sir William Penn. But early in 1662 there came a change. The colleagues whose bacchanalian habits and social position had made them so attractive began to prove irksome, and their insistence on their superior experience and status galled Pepys's pride. In his isolation, he sought for ways by which he could show himself their equal. He had not far to look, for his fellow officers were anything but attentive to business. "So to the office," Pepys wrote, "where I do begin to be exact in my duty there and exacting my privileges and shall continue to do so." He had found his vocation.

Naval Administration.—It was not in Pepys's nature to do things by halves. Having resolved to do his duty, he set out to equip himself for its performance. In the summer of 1662, he occupied his leisure moments by learning the multiplication table, listening to lectures on shipbuilding, and studying the prices of naval stores: "into Thames Street beyond the Bridge, and there enquired among the shops the price of tar and oil, and do find great content in it, and hope to save the King money by this practise." At the same time, he began his habit of making careful entries of all contracts and memoranda in large vellum books—beautifully ruled by Mrs. Pepys and her maids—and of keeping copies of his official letters.

The qualities of industry and devotion to duty which Pepys brought to the service of the Royal Navy became realized during the Second Dutch War of 1665–67—years in which he remained at his post throughout the Plague and saved the navy office in the Fire of London. Before trouble with his eyesight caused him to discontinue his diary in 1669—an event followed by the death of his wife—these qualities had won him the trust of the king and his brother, the duke of York, the lord high admiral. In 1673, in the middle of the Third Dutch War, when York's unpopular conversion to Catholicism forced him to resign his office, Pepys was appointed secretary to the new commission of admiralty and, as such, administrative head of the navy. In order to represent it in Parliament—before whom he had conducted a masterly defense of his office some years before—he became member first for Castle Rising, and, later, for Harwich. For the next six years he was engaged in stamping out the corruption which had paralyzed the activities of the navy. His greatest achievement was carrying through Parliament a program which, by laying down 30 new ships of the line, restored the balance of sea power, upset by the gigantic building programs of France and the Netherlands. In his work both at the Admiralty and in Parliament Pepys's unbending passion for efficiency and honesty (combined with a certain childlike insistence on his own virtue and capacity for being always in the right) made him powerful and bitter enemies. One of these was Lord Shaftesbury, who in 1678 endeavoured to strike at the succession and at the Catholic successor, the duke of York, by implicating Pepys in the mysterious murder of the London magistrate Sir Edmund Berry Godfrey (*q.v.*), the crime on which the full credulity of the populace in the "Popish Plot" depended. When Pepys produced an unanswerable alibi his enemies endeavoured to fasten Godfrey's murder on him indirectly by accusing his confidential clerk, Samuel Atkins. Despite the third-degree methods employed against him, Pepys also proved an alibi for Atkins, who would otherwise almost certainly have perished. Six months later, his enemies brought into England a picturesque scoundrel and blackmailer called John Scott, who had begun his life of crime in what today is Long Island, N.Y., and whom Pepys had endeavoured to have arrested at the time of Godfrey's death on account of his mysterious activities disguised as a Jesuit. Pepys was flung into the Tower on an absurd charge of treason brought against him by Scott and supported by the Exclusionists in Parliament, as also on a minor and equally unjust charge of popery, brought against him by a dismissed butler whom he had caught in bed with his favourite maid. Had not Charles II almost immediately dissolved Parliament and prevented a new one from meeting for a further year and a half, Pepys would have paid the penalty for his loyalty, efficiency, and incorruptibility with his life. He employed his respite with such energy that by the time Parliament met again he had completely blasted the reputation of his accuser by collecting circumstantial details of his infamies from almost every country in the civilized world.

In 1683, when the king felt strong enough to ignore his opponents, Pepys was taken back into the public serivce. He had accompanied the duke of York in the previous year on a voyage to Scotland, and he now sailed as adviser to the earl of Dartmouth to evacuate the English garrison of Tangier—a voyage which he described in a further journal. On his return, in the spring of 1684, he was recalled by Charles II to his old post. Entitled secretary of the affairs of the Admiralty of England and remunerated by a salary of £2,000 per annum, he combined the modern offices of first lord and secretary of the Admiralty, both administering the service and answering for it in Parliament. For the next four and a half years, including the whole of James II's reign, Pepys was one of the greatest men in England, controlling the largest spending department of state. With his habitual courage and industry he set himself to rebuild the naval edifice which the inefficiency and corruption of his enemies had shattered, securing in 1686 the appointment of a special commission "for the Recovery of the Navy." When, at the beginning of 1689, after James II had been driven from the country, Pepys retired, he had created a navy strong enough to maintain a long ascendancy in the world's seas. Hitherto there had been brief spells when the emergence of a naval genius like Sir Francis Drake and Robert Blake had given England a temporary advantage over its maritime neighbours, but for long periods the English "sovereignty of the seas" had been an idle boast. When Pepys became associated with the navy in 1660 the line of battle had consisted of 30 battleships of a total burden of approximately 25,000 tons and carrying 1,730 guns. When he laid down his office he left a battle line of 59 ships of a total burden of 66,000 tons and carrying 4,492 guns. Not only had he doubled the navy's fighting strength; he had given it what it had never possessed before and what it never again lost—a great administrative tradition of order, discipline, and service. He had made the scabbard of the sword which the great 18th-century admirals used.

"To your praises," declared the orator of the University of Oxford, "the whole ocean bears witness; truly, sir, you have encompassed Britain with wooden walls." Pepys's last 14 years, despite attempts by his political adversaries to molest him, were spent in honourable retirement in his riverside house in York Buildings, amassing and arranging the library which he ultimately left to Magdalene College, Cambridge, corresponding with scholars and artists, and collecting material for a history of the navy which he never lived to complete, though he published in 1690 a prelude to it, describing his recent work at the Admiralty, entitled *Memoires of the Royal Navy*. He died on May 26, 1703, at the Clapham home of his former servant and lifelong friend, William Hewer. His fellow diarist, John Evelyn, wrote of him: "He was universally loved, hospitable, generous, learned in many things, skilled in music, a very great cherisher of learned men of whom he had the conversation."

The Diary.—The diary by which Pepys is chiefly known was kept between his 27th and 36th year. Written in Thomas Shelton's system of shorthand or *Tachygraphy* with the names in longhand, it extends to 1,250,000 words, filling six quarto volumes in the Pepys Library. It is far more than an ordinary record of its writer's thoughts and actions; it is a supreme work of art, revealing on every page the capacity for selecting the small as well as the large essential that conveys the sense of life, and it is probably, after the Bible and James Boswell's *Life of Samuel Johnson*, the best bedside book in the English language. Nor was Pepys only an artist: he possessed in a unique degree the quality of complete honesty, so that he excluded from his record nothing which seemed to him vital, however much its inclusion told against himself. He set down not only his major infidelities but those petty weaknesses which men endeavour to conceal even from themselves. In this sense he is both Everyman and the recording angel; his diary paints not only his own infirmities but the frailty of all mankind.

BIBLIOGRAPHY.—*Diary:* After the successful publication of John Evelyn's diary in 1818, Pepys's diary was transcribed—with great accuracy—by John Smith, later rector of Baldock, Hertfordshire, at the instance of the master and fellows of Magdalene College, Cambridge. About a quarter of it, ed. by the 3rd Lord Braybrooke, was published as *Memoirs of Samuel Pepys, Esq., F.R.S.*, 2 vol. (1825). Many fuller editions followed, until the whole diary with the exception of about 50 short passages omitted on grounds of decency, ed. by H. B. Wheatley, appeared in 10 vol. (1893–99). The St. Olave edition, 18 vol., was published in New York (1903). Later editions and selections include *Everybody's Pepys*, abridged and ed. by O. F. Morshead (1926); *The Diary*, selections ed. by J. Warrington, Everyman's Library, 3 vol. (1953).

(A. Br.)

PERAK, a state of the federation of Malaysia (*q.v.*), is the largest of the western Malayan states and a constitutional sultanate. Area 7,980 sq.mi. (20,668 sq.km.). Pop. (1961 est.) 1,384,321. Including a large part of the west coast plains, the state centres upon the Perak River (252 mi. [406 km.]), which runs roughly north to south between the little-used heights forming the central range (over 7,000 ft. [2,135 m.]) to the east and another range paralleling the river to the west. The river turns westward only at Telok Anson and meanders through a silting estuary to the Strait of Malacca. Although the Perak River acted as an artery for the original Malay community and is still symbolized by the sultan's seat beside it at Kuala Kangsar (pop. [1957] 15,302), it is insignificant in the modern economy of the state which is based on the tin mines of the Kinta Valley, particularly around Ipoh (*see* KINTA; IPOH). This area produces half of Malaya's output of tin. In addition, the state has more than 600,000 ac. (242,820 ha.) under rubber (equally distributed between estates and smallholdings), 100,000 ac. (40,470 ha.) under paddy (notably at Krian), large commercial plantations of coconut, and the biggest fish production in Malaya.

Perak's agricultural development dates from the end of the 19th century when tin mining changed focus from Taiping to Ipoh, and the great acreages of rubber and coconut finally surpassed the mines in value and number of people employed. As rubber and tin necessitated immigrant labour and capital, Perak has a complex racial structure, Chinese forming 44% of total population, Malays 40%, and Indians 15%. The state capital, Ipoh (125,770), Taiping (48,206), and the other mining towns are predominantly Chinese, the Malays forming majorities only in the agricultural districts of Krian, Sungei Manik, and Changkat.

About 6,000 sq.mi. (15,540 sq.km.) of Perak are under forest. The jungle-covered ranges are scarcely inhabited and uncrossed by roads, the Tapah-Cameron Highlands Road being the dead end. The state has a mountainous border with Thailand to the north. There is a good network of modern roads supported by the Malayan Railway along the foothills; a branch line runs to Telok Anson (37,000) in the south which handles steamers carrying copra and rubber along the coast. The Taiping Railway to Port Weld, the oldest in Malaya, is a relic now used for transporting firewood and charcoal from the Matang mangrove. Perak is served by the main airport at Penang but has airfields at Taiping and Ipoh for inland services. For historical aspects *see* MALAYA: *History*.

(E. H. G. D.)

PERAVIA, a province in southern Dominican Republic. Area, 626 sq.mi. Pop. (1960) 106,736. It is largely mountainous, being bounded on the north by the Cordillera Central and crossed in the central part by the Sierra de Ocoa (to 5,678 ft.). The southern coastal plain is semiarid. Peravia is a leading coffee producer and a significant producer of rice and peanuts. The province was created in 1944 from parts of Trujillo (San Cristóbal) and Azua provinces; the older name, Trujillo Valdez, was changed to Peravia in 1961. The provincial capital is Baní (pop. [1960] 14,472).

(D. R. D.)

PERCENTAGE, a relative value indicating hundredth parts of any quantity. The word is used in statements that fail to specify the value; *e.g.*, "In Burma a high percentage of the people are Buddhists." When the percentage is specified numerically the term per cent is substituted; *e.g.*, "In Burma about 90 per cent of the people are Buddhists." One per cent (symbolized 1%) is a hundredth part; thus 100% represents the entirety and 200% specifies twice the given quantity. For example, 1% of 1,000 chickens equals $\frac{1}{100}$ of 1,000, or 10 chickens; 20% of the quantity is $\frac{20}{100} \times 1{,}000$, or 200. These relationships may be generalized as

$$x = \frac{PT}{100} \qquad (1)$$

where T is the total reference quantity chosen to indicate 100%, and x is the quantity equivalent to a given percentage P of T. Thus in the example for 1% of 1,000 chickens: T is 1,000, P is 1, and x is found to be 10.

In many commonly occurring percentage problems x and T are known, and the percentage of T that x represents is sought. For such cases it is convenient to use equation (1) in the form

$$P = \frac{100x}{T} \qquad (2)$$

A frequent application of equation (2) is in calculating percentage of profit or loss in business transactions. Suppose a retailer buys a television set at a wholesale price T of $80 and sells it for $110 at a profit x of $30. From the equation his percentage profit is $\frac{100 \times 30}{80}$, or 37.5%. Similarly, a London bookseller may put a novel on sale, lowering the price T of 20*s.* to 17; a reduction x of 3*s.*, or 15%. (*See* also CAPITAL AND INTEREST: *Interest: Rate of Interest.*)

In statistics the notion of cumulative percentage (percentile, centile) is in common use. For example, a student who scores at the 83rd centile on a history examination has exceeded the performance of 83% of the students with whom he is being compared. Related quartile and decile systems are discussed under STATISTICS: *Averages and Dispersion.* The probability that a given event will occur may be expressed as a percentage (or its equivalent decimal value or fraction). A perfectly balanced coin will tend to fall head-side-up once in every two tosses; this probability may be given with equal accuracy as $\frac{1}{2}$, .50, or 50% (*see* PROBABILITY, MATHEMATICAL).

(C. Ce.)

PERCEPTION is the process by which a living organism becomes aware of stimuli. Though the term has become well established through traditional usage, some modern psychologists prefer to use the word perceiving to emphasize that a process or activity is involved. In 1765 the Scottish philosopher Thomas Reid distinguished between sensation (*q.v.*) and perception, applying the term sensation to the immediate data that come directly from stimulation and the term perception to the larger awareness that includes the reference of these sensations to the stimulus. This distinction held until the third decade of the 20th century when, under the influence of Gestalt psychology (*see* GESTALT PSYCHOLOGY), the concept of sensation tended to drop out of use and psychologists began to direct their attention to the larger systems of sensory stimulation, which, since objective reference is implicit in them, properly involve perceiving.

These definitions of sensation and perception, as well as the material that follows, are based on the commonplace assumption that there really are physical entities to be perceived. However, it should be noted that there are profound disagreements among philosophers concerning the very existence of physical reality; these are more fully discussed under IDEALISM and KNOWLEDGE, THEORY OF.

THEORIES OF PERCEPTION

A theory of perception undertakes to explain how the organism becomes aware of itself and of the external world. If an organism is to survive and succeed, it must have adequate information about its environment; and there have been several answers to the question of how is it possible for organisms to perceive correctly.

Discrimination.—A laboratory animal or person must react

discriminatively to objects or situations if others are to have evidence that the subject is perceiving. It is much easier to be assured of the occurrence of adequate discrimination than to know whether the process is consciously or unconsciously mediated. Unfortunately, the inner experiences of another organism cannot be directly observed; however, its manifest reactions can.

A rat can learn always to choose between two disks of equal size if the brighter disk consistently marks the door to a food box. The rat thus detects a difference in brightness. In a sense the animal may be said to be aware of the disks, but actually that question does not have to be raised; clearly, it defies an empirical answer. A man engrossed in conversation with his dinner companions finds that the little pile of nuts by his plate has disappeared and that he even has a nut in his mouth. Another man across the table saw him actually eat the nuts. He discriminated the nuts from other inedible objects which he did not try to ingest. Most psychologists would say that such well-habituated discrimination is unconscious, although an exact answer to that question depends on the definition of consciousness.

This general rule holds: efforts to study how other organisms perceive must be defined in terms of how they discriminate among stimuli.

Representation in Kind.—The Greeks believed that objects emit faint copies of themselves, copies which are transmitted by the senses to the sensorium which becomes aware of the object by perceiving its copy. While this view was too naïve to survive in the age of science, the basic idea recurs again and again in psychological theory. For instance, John Locke in 1690 distinguished between primary and secondary qualities of perceived objects. Primary qualities are those for which the experience resembles its object, like spatial extension. Secondary qualities are those for which the experience does not resemble its object, like colour. In modern terms for secondary qualities there is a functional dependence between experience and stimulus without representation in kind: experienced redness of external objects depends upon light of long wavelengths, but there is nothing long or undulatory about the experience red itself (*see* VISION).

About 1920 the Gestalt psychologists proposed psychophysiological isomorphism as a theory of perception. In respect to spatial relations this theory holds that there is a point-to-point correspondence between the experience and the underlying brain pattern, a correspondence such that all the spatial orders of one system are preserved in the other, although shapes and magnitudes may not be preserved. In other words, the correspondence between the brain pattern and the experienced pattern is viewed as topological, but not necessarily topographical. The chief evidence for this view comes from the physiological discovery that excitation of the visual area of the brain corresponds topologically, point for point, to the excitatory pattern on the retinas (*see* TOPOLOGY, GENERAL).

Thus there are four patterns, all held topologically isomorphic with one another: (1) the projected stimulus pattern of light; (2) the pattern of excitation on the retinas; (3) the neurally projected pattern on the visual areas of the brain; and (4) the pattern as experienced. In this way, for the visual perception of bidimensional spatial patterns, the simple theory of perceptual representation of the object in kind, a modern theory of primary qualities, is preserved.

The Gestalt psychologists carried isomorphism further. They believe that the principle holds for perceiving tridimensional visual space, that visual awareness of depth and solidity corresponds to a tridimensional field of excitation in the brain. They also hold that experiences of intensity, time, and movement are isomorphic. In certain cases this theory requires that the characteristics of the stimulus object (which are represented functionally but not in kind in the initial phases of excitation) must be reconstituted in the brain fields that mediate the experience. For instance, depth is represented on the retinas, not in kind but by disparity between the two retinal images. Isomorphism requires that this disparity operate in the action of the nervous system to reconstitute a solid excitatory field in the visual areas of the brain. The evidence was not yet conclusive in the 1960s as to how or even whether this reconstitution of the stimulus field actually occurs in the brain.

Functional Representation.—It is quite clear that not all perceptual qualities are primary; some are secondary. Not all perceptual representation is in kind; some of it is a correspondence between dissimilars, a correspondence that is adequate because it is functionally specific. The longest visible wavelengths of light always look red if they fall, uncombined with other wavelengths, upon the retina of a man who is not colour-blind. That is a functional correspondence of dissimilars, the case where isomorphism in perception is certainly not the correct principle.

This view is fully as old as Johannes Peter Müller's (*q.v.*) theory of specific nerve energies, first formulated in 1826 as a protest against the ancient doctrine that perceptual representation is always in kind. Müller argued for the existence of five specific nerve energies or qualities, one for each of the five classical senses. The sensorium perceives, he said, not the properties of the objects themselves but the properties of the nerves that the objects affect. Thus light and the experience of seeing are quite different. The reason that a person knows there is light when he sees is that there is, according to Müller, a "specific irritability" of the retina which makes it most easily excited by light. C. S. Sherrington later (1906) used the term "adequate stimulus" to designate this specificity of relation between a sense organ and its normal stimulus. A misleading experience occurs when an unusual stimulus is effective, in spite of its inefficiency, as when pressure on the eyeball arouses the experience of coloured patterns.

It would seem that all perceptual activities must imply functional representation of the perceived characteristics of the stimulus, both in the brain and in the experience. Sometimes, but not always, this representation is in kind; *i.e.*, isomorphic. Presumably there is a topological representation of the stimulus characteristics in perceiving temporal duration, stimulus intensity, visual and tactual spatial patterns in two dimensions, and visual, tactual, and auditory movement.

Perceptual Context.—Thus far only the sensory core of perceiving, a core which in familiar perceptions is adequate by itself for the identification of the stimulus object, has been considered. Often, however, the core alone is insufficient to constitute the complete perception that the organism seeks. A context must be added to the core if identification of the perceived object is to be satisfactory. I smell a rose. What have I perceived? An odour. But if, by association, there is added to the odour a visual image of a rose, then this visual context, accruing to the olfactory core, provides greater specificity of meaning and further completes the perception. I see a face. It is strange. Then a name comes to mind, and, because of that added context, I have recognized the face.

This context theory of perception is basically an associative theory of perceptual meaning. It was first elaborated by George Berkeley in 1709, then developed by the associationists (Thomas Brown in 1820, James Mill in 1829, Wilhelm Wundt in 1874), and finally made the basis for Wundt's "mental chemistry" in which meaning is always explained by compounding, by the association of two or more conscious items (*see* ASSOCIATION, MENTAL). The associations that form these identifying contexts are often learned, but they may be inherited reflexes. For instance, a human infant instinctively gives the startle reflex when stimulated suddenly by a loud sound. That reflex is not learned, yet it constitutes the context which makes the sound perceived as "something to be startled by." Similarly a protozoan that turns away from the light may be imagined to perceive the light as something to be avoided. The light is the core; the turning, the context.

The context theory of perception was named by E. B. Titchener in 1909. His chief contribution was to note that contexts may be conscious or unconscious, that novel perceptions generally require conscious contexts for their specification, but that the conscious context tends to drop off as the perception becomes familiar, leaving the meaning to be carried unconsciously and evidenced by the adequate discriminatory behaviour of the organism. When a person first sees the word "argali" the perception is inadequate. He does not know what the word means. When he has been told that

an argali is a kind of wild sheep or has been shown a picture of one, then for a while the verbal core will arouse an identifying context: the word sheep or the visual image of an argali. When the word has become familiar, this awareness of context drops off. He can now comprehend the meaning of argali without concentrating on the context, as is evidenced by the fact that later on he can demonstrate his understanding of a text which contains the word. New words need contexts, but in most reading there is no time for the perceptual contexts to accrue. Thus the context theory recalls that evidence of perceiving is found in discrimination.

The foregoing theories of perception are supplementary and not mutually exclusive. In perceiving, the perceived characteristics must have functional representation in the brain. Sometimes this representation is isomorphic, and there is further evidence that in some cases physiological mechanisms reestablish a topological correspondence between the stimulus field and the brain field, even when such correspondence has been lost in the initial phases of excitation.

TYPES OF PERCEPTION

This discussion of theories of perception indicates that perceiving may be consciously or unconsciously mediated, that the functional adequacy of perceiving normally enables the organism to obtain correct information about its environment and that a perception, especially a novel one, normally receives further specification by the addition to its sensory core of a context, either a learned association or an innate reflex. It is now proper to discuss further the reconstitution of objects in perception, the perception of relations, and unconscious discrimination.

Perceptual Reconstitution.—Stereoscopic vision furnishes one of the best examples of how the characteristics of the stimulating object are reconstituted in perception (*see* BINOCULAR INSTRUMENT: *Stereoscopes*). A solid object, viewed with both eyes, produces somewhat disparate images on the two retinas. Since both images are seen in a single perceptual field, one might expect to see this disparity as a double image. Instead, one perceives a solid object in three dimensions, with no doubling, in spite of the fact that the two retinal images would not coincide in superposition.

The fact that one sees objects single in binocular vision thus is also an instance of this principle of reconstitution. In this case a little is known about the physiological basis for the perception: corresponding points on the two retinas are projected to the same region of the brain.

Gestalt psychologists have made a great deal of what has been called the constancy phenomenon; that is to say, the tendency to see objects as constant in size, shape, brightness, and hue, even when the immediate stimulation from them varies greatly. For instance, a receding object does not lose apparent size nearly so rapidly as its retinal image diminishes. Experiments have shown that in free binocular vision an illuminated disk in the dark may not appear to diminish in size at all as the disk recedes from a distance of 20 ft. to a distance of 200 ft., although the retinal image under those conditions shrinks to $\frac{1}{10}$ of its initial linear size. Such perceived constancy depends, however, on the availability to the organism of clues to the distance, so that the perceiving mechanism can, as it were, correct the perception for the distance. When the clues to distance are reduced by eliminating the use of one eye and all reference-objects from the intervening space, then the perceived size is found to diminish with the size of the retinal image.

It is obvious that perceptual constancy can be of great advantage to the organism in its struggle for survival and success. Experiments show that chickens, trained to choose the larger grains of corn and to let the smaller lie, will choose remote large grains which have small retinal images, in preference to near small grains which have larger retinal images. They tend to choose larger objects rather than responding directly to the size of the retinal image.

The shape of objects also tends to be perceptually reconstituted when oblique viewing changes the shape of the retinal image. As the perceiver shifts from direct to oblique regard, a circle continues to look like a circle, even though its retinal images may have become narrow ellipses.

The apparent brightness of an object likewise tends to remain constant in spite of varying illumination. Coal, recognized as coal, looks black even in bright sunlight. Snow, perceived as snow, looks white even in shadow. Actually the snow in shadow may be darker than the coal in sunlight. If both objects are viewed through tubes, which obscure the clues to their nature as objects and reveal only small circular patches of the two surfaces, then the illuminated coal will appear much brighter than the shaded snow.

Discrete displacement of the retinal image will, with the right speeds and spacings, give rise to the visual experience of continuous movement. The motion picture makes use of this principle of apparent movement (*see* VISION: *Space Perception: Visual Perception of Movement*). Actually the interpretation of the discrete displacement as continuous movement is often a reconstitution of an original stimulus. A moving object is seen clearly only when the eyes move with the object, allowing the image momentarily to remain stationary on the retina. Thus discrete retinal displacement is the rule in perceiving continuous movement, and the perception of continuity of movement is really a reconstitution of the original continuity.

Auditory localization also illustrates how the stimulus situation is reconstituted in perceiving. A sound that originates in the median plane between the two ears affects both ears equally and is heard not as a double sound, one on the right and another on the left, but as a single sound localized correctly in the median plane. A sound from the right, however, coming earlier and louder to the right ear is localized at the right. Thus, in general, any sound that comes to both ears but is either earlier or louder at one ear will be localized as coming from the side of that ear (*see* HEARING: *Localization of Sounds*).

The general rule is that perception, insofar as it is adequate, tends to reconstitute the characteristics of the stimulus object. Many of these principles were worked out in Gestalt psychology although such basic facts as singleness of vision with two eyes have been recognized since antiquity.

Perception of Relations.—For the most part perception is relativistic rather than absolute. An object has no perceived size except as it is compared with another object. Precise judgments of tonal pitch, of visual brightness, and even of hue are possible only by reference to some standard. Accurate perception is always the perception of a relation.

It is well known that the perception of pitch is relative and that a melody or harmony depends on the relations among the musical notes and not on their absolute pitches. In the same way the visual perception of brightness is relative. If a man or other animal learns to choose the brighter of two grays, he will take a given gray when it is combined with a darker one and reject it when it is combined with a lighter one. Human adults, children, apes, dogs, rats, and bees all react in this relativistic manner.

The visual perceptions of up and down, of right and left, are relative. It has been known since Johannes Kepler (1604) that the optical image of the external world is inverted, up for down and right for left, in its projection on the retina of the eye, and the question used to be raised as to why we see right side up when the retinal image is upside down. Actually the image itself, being relative, is not distorted, for in it up is the opposite of down and right the opposite of left, whichever way the image is turned. It is, however, to this inverted image that the appropriate behaviour becomes attached by association, so that one reaches down to touch an object that is projected upon the top of the retina. Sometimes an experimental subject wears for a week a system of lenses that reverses this already inverted retinal image; then, since the image is now right side up, the world at first looks upside down. Presently, however, as the associations with behaviour become reversed, the inverted image seems to turn right side up again. When the lenses are removed the associations must again be reversed by experience.

Unconscious Discrimination.—Whether a discrimination is

to be regarded as conscious or unconscious depends almost entirely upon the definition of consciousness (*q.v.*). It is usual, however, to regard an accurate discrimination as unconscious when it leaves no memory trace of its occurrence, when the perceiver cannot say minutes or even seconds afterward whether he perceived or what he perceived. Familiar, well-habituated discriminations fall in this class, as do all rapid discriminations. A man can perceive a familiar designated object quickly when it lies on a table with 99 other strange objects, and he can pick out the designated object again and again from different sets of strange objects, quickly and accurately. He must indeed "see" the other objects in order to reject them and continue his rapid search for the specified object, but he cannot afterward tell much about these other objects. This hurried negative discrimination of wrong objects, discriminated in order to reject them, is practically unconscious—for they do not stick in memory.

There have been experiments in which a discrimination has been determined or aided by clues of which the discriminator declares he was fully unaware. In the same way judgments can be passed without the judge being aware of the motives and prejudices that influence his thought.

There is also the case of contradictory perception which occurs with hypnotism. (*See* HYPNOSIS.) For example, the hypnotist may suggest to the hypnotic subject that they two are alone in the room, although actually there is a third person present. The subject then becomes "blind" to the third person and acts consistently as if he were not there. Nevertheless, the subject never collides with the third person, never tries to sit where the third person is sitting. If the hypnotist suggests that the subject take the chair occupied by the "invisible" person, the subject will find excuses and reasons for not doing what is, in fact, impossible for him to do. In this case it appears that the subject "sees" the man to whom he is blind so that he may know not to "perceive" him.

Social Perception.—This term, which came into vogue in the late 1940s, is used to designate either: (1) such perceptions of social phenomena as the perception of anger or danger; or (2) those perceptions that are understood by reference to their social determinants.

The first class of social perceptions presents no new problems or principles. It consists of perceptions of social meanings in which the determinants and even the sensory cores may be unreportable by the perceiver and in that sense are unconscious. Thus a man may perceive anger in another man without knowing what bits of behaviour or facial expressions form the basis for his perception. Nor is this case different from the perception of the constant apparent size of a receding object when the observer does not know that he is unconsciously taking perceived distance into account.

Of the other class of social perceptions it has been said that the perceived pattern of the external world always mirrors the pattern of the needs of the perceiver. There are many well-known subjective determinants of perception, and by no means do they all operate to create illusion, for true knowledge of the apparently real world is one of the fundamental needs of the organism. Perceptual mechanisms tend to reconstitute the perception in such a manner as to increase the accuracy with which perception represents external objects and other events. Stereoscopic perception of depth, the object constancies, and the perception of continuous movement with cinematic discontinuity are all cases in point.

Organisms have, however, many other needs besides knowledge of the truth. Illusion may be created by the projection of wishes into perception. "If she be not fair to me, what care I how fair she be." The Thematic Apperception Test (*see* PSYCHOLOGICAL TESTS AND MEASUREMENTS: *Tests of Personality and Temperament*) samples the needs of a subject or patient by having him describe what he sees in a series of pictures that can be given many interpretations. Sometimes children see desired objects as larger than undesired ones when all objects are of the same size; this tendency to subjective distortion has been measured in experiments that provide a set of neutral comparison objects.

Social determinants operate like any of the other determinants of perception. They may work, for instance, in a defensive manner, as when a person, given sufficient time to perceive a rapidly exposed word, nevertheless fails to perceive it because it is an unwelcome-word, one that embarrasses or shames him. Perceptual defense, as it is called, is an escape mechanism by which the organism avoids, either completely or partially, an intolerable experience. This case belongs with the contradictory perceptions of the hypnotic state, for presumably the respondent must first have "seen" the word in order to be able to exclude it from his immediate memory.

(E. G. BOR.)

PERCEVAL, an important hero in Arthurian romance and Grail winner in the oldest extant account of the Quest for the Holy Grail, *Le Conte del Graal* or *Roman de Perceval*, written between 1179 and 1191 by Chrétien de Troyes (*q.v.*). He is not mentioned as one of Arthur's knights in Geoffrey of Monmouth's *Historia regum Britanniae*, or in Wace's poetic version of it, although the name Peredur, which in medieval Welsh literature is equated with Perceval, is mentioned in an early Welsh poem *Y Gododdin* (*see* WELSH LITERATURE).

Perceval first appears as one of Arthur's knights in a list of names at the beginning of *Erec*, the 12th-century romance by Chrétien de Troyes, and he is promoted to the rank of hero in Chrétien's last romance, *Le Conte del Graal*. Here his chief characteristic is an uncouth innocence, a variant of the "Great Fool" theme, and this remains his dominant characteristic in Arthurian romance. In Chrétien's poem, Perceval's father and brothers having been killed in pursuit of chivalry, he is brought up by his mother in isolation from the world and in complete ignorance of knighthood. He meets some knights by chance, plies them with naïve questions and then determines to become a knight. His ignorance is shown by his strange behaviour during his journey and on his arrival at Arthur's court, but a great destiny is prophesied for him by a damsel and a court fool. He visits the Grail Castle where he is received by the Fisher King who has been maimed by a spear thrust through his thighs. There Perceval sees a strange procession of a squire bearing a lance, two squires carrying ten-branched candlesticks, a damsel holding a *graal* which gives forth great light, and another damsel with a silver platter, but he fails to ask the question which would have healed the Fisher King and restored the Waste Land. It is only after leaving the Grail Castle that he learns of the disastrous consequences of his silence, first from a damsel, his cousin, and then from a hideous damsel. He sets out to find the Grail, and in the rest of the romance this quest for the mysterious vessel is associated with Perceval's education in chivalry. He has a lady, Blancheflor, but unlike Lancelot (*q.v.*) his chivalry is not inspired by human love but is given a more spiritual motivation. As he seeks for the Grail, so he gradually learns the true meaning of chivalry and its close connection with the teachings of the Church. Chrétien never finished the romance, although a number of continuations were

written, but it seems likely that had he done so, Perceval would have returned to the Grail Castle and broken the spell by asking the question about the Grail.

Three other works appear to be based on Chrétien's poem, although there is some uncertainty as to their exact relationship with it. These are the *Parzival* of Wolfram von Eschenbach (*q.v.*), the Welsh *Peredur* in the *Mabinogion* (*q.v.*), and the 14th-century Middle English rhymed romance, *Sir Perceval of Galles*. Perceval's character remains fairly consistent throughout Arthurian romance, although his position in the hierarchy of Grail winners changes. He is still the principal hero of two other French Grail romances, both of the 13th century, the *Didot Perceval* and the *Perlesvaus*, a long and complicated romance which relates the adventures of Gawain, Lancelot, and Perceval (Perlesvaus) in the Quest for the Grail. However, in *La Queste del Saint Graal* of the Vulgate cycle, the version which was to be the most widely read and to have the greatest influence on later works such as the prose *Tristan* (*see* TRISTAN) and Sir Thomas Malory's *Morte Darthur*, Perceval is only one of three knights (the others being Galahad and Bohort) to achieve the Quest and is superseded by Galahad as chief Grail winner and as the knight entitled to the "Siege Perilous," the seat at the Round Table reserved for the knight successful in the Grail Quest. Perceval seems to have been displaced by Galahad for two reasons. First, to link the Grail Quest closely to the story of Lancelot, and to give it its true significance, the Grail winner in the *Lancelot* prose cycle is made Lancelot's own son Galahad; second, the Grail theme itself has here been given a more austerely theological significance which demands a new Grail winner without Perceval's past, one whose genealogy could be traced back to David and whose very name Galahad has been linked with the biblical place name, "Gilead," one of the mystic appellations of Christ. Perceval, however, both in the Vulgate-cycle Quest and in Malory still plays an important part. He preserves that quality of childlike innocence, already to be found in Chrétien's Perceval, and it is this which protects him from temptation and sets him apart from the other knights. Unlike Galahad he is not allowed to look into the Grail, but he sees in visions many of its mysteries and never returns to ordinary earthly life.

Perceval figures as the hero of Wagner's last opera, *Parsifal* (1882), in which, after various adventures, he heals the wounded Grail Guardian with the sacred spear and restores the service of the Grail to its former glory.

BIBLIOGRAPHY.—J. L. Weston, *The Legend of Sir Perceval*, 2 vol. (1906–09) is a general study, but some of her theories are outdated; it is not generally accepted that Gawain preceded Perceval as Grail winner or that a Perceval Quest once formed part of the *Lancelot* Vulgate cycle. For a detailed bibliography of texts and discussion of problems *see* J. D. Bruce, *Evolution of Arthurian Romance from the Beginning down to the Year 1300*, 2nd ed. (1927); R. S. Loomis (ed.), *Arthurian Literature in the Middle Ages* (1959). (E. M. K.)

PERCEVAL, SPENCER (1762–1812), English statesman and prime minister from 1809 until his assassination in 1812, was born in London on Nov. 1, 1762. He was the second son of the 2nd earl of Egmont. Educated at Harrow and at Trinity College, Cambridge, he was called to the bar by Lincoln's Inn in 1786 and became a king's counsel in 1796. In the same year he entered Parliament as member for Northampton and supported the administration of Pitt. In 1801, on the formation of the Addington government, he was appointed solicitor general, and from 1802 till Pitt's death in 1806 he was attorney general. When the king dismissed the Grenville ministry in March 1807, Perceval, an ardent opponent of Catholic emancipation, became chancellor of the exchequer and chancellor of the duchy of Lancaster under the duke of Portland, whom in 1809 he succeeded in the premiership. On May 11, 1812, Perceval was shot dead in the lobby of the House of Commons by a madman named John Bellingham, a bankrupt with a grievance against the government who had vainly applied to the prime minister for redress. Bellingham, though insane, was hanged on May 18.

See D. Gray, *Spencer Perceval* (1963). (A. AL.)

PERCH, either of two closely related, edible, freshwater bony fishes: the common perch (*Perca fluviatilis*), generally distributed over northern Eurasia, and the yellow perch (*P. flavescens*), found in eastern North America. Together with the pike perches and darters they comprise the Percidae, a family of typical spiny-rayed fishes. Perches inhabit rivers and lakes but thrive best in waters with a depth of more than three feet; in large lakes they frequently descend to 300 ft. or more. The European form occurs in Scandinavia as far north as the 60th parallel; but the northern limit of the American species is about the 55th parallel. The species exhibit many variations in shape, some specimens being high-backed, others low and long-bodied. A rich greenish brown, with golden reflections, covers the back and sides, which are ornamented with five or seven dark crossbands. A large black blotch occupies the membrane between the last two spines of the dorsal fin; the pelvic, anal, and lower parts of the caudal fins are bright vermilion.

L. M. CHACE FROM THE NATIONAL AUDUBON SOCIETY

YELLOW PERCH (PERCA FLAVESCENS)

Perches are carnivorous and voracious. They are highly esteemed as food in inland regions. Exceedingly prolific, perch begin to spawn when three years old, depositing, in April or in the first half of May, the 10,000 to 40,000 eggs, which are extruded in long, netlike narrow bands on water plants. Perch often become so numerous and crowded that none has enough food and all remain small; they are then undesirable for food.

Many spiny-rayed fishes belonging to a variety of closely related families are called perch, as surf perch (Embiotocidae) and some sea bass (Serranidae); distantly related families of the order Percopsiformes are also called perch, as trout perch and pirate perch. *See* FISH; *see* also references under "Perch" in the Index.

(C. HU.)

PERCHE, a district of northern France, on the borders of Normandy, lies mainly in the east of the *département* of Orne, with extensions into the adjacent *départements* of Eure, Eure-et-Loir, and Sarthe. Perche consists of hilly country, with summits between 700 and 1,000 ft. (213 m. and 304 m.), enclosing the upper basin of the Huisne tributary of the Sarthe and forming the watershed between it and eastward drainage to the Eure and Loir. It is a district of pastoral farming, chiefly concerned with breeding cattle and dairying and especially famous for its breed of draft horses (Percheron). It lies north of the limit of viticulture, but cider-apple orchards are a ubiquitous feature of its hamlets and scattered farmsteads. Mortagne and Nogent-le-Rotrou are the chief market towns and in the Middle Ages were at different times capitals of the County of Perche. (AR. E. S.)

PERCHTA: *see* BERCHTA.

PERCUSSION INSTRUMENTS, the name given to those musical instruments from which sound is produced principally by striking. They are divided into two main classes which sometimes overlap: idiophones, in which sound is produced by striking or clashing together hard substances—wood, metal, etc.—and membranophones, in which sound is produced by vibrating a stretched skin. There are separate articles on all the main percussion instruments or classes of instruments in use in the modern orchestra or dance band; this article traces the development of early instruments, and also describes some unusual and interesting examples of instruments of this type used in folk music or in ancient civilizations. (*See* also ORIENTAL MUSIC; CHINESE MUSIC; JAPANESE MUSIC; INDIAN MUSIC; AFRICAN MUSIC.)

The first stage in the making of music and the development of musical instruments began when primitive man stamped on the ground or slapped his own body to produce rhythmic sound. The sounds produced varied in tone according to whether the heels or toes were used in stamping or whether bony or fleshy parts of the body were struck in slapping. With this preinstrumental music is associated the stamped pit, a hole dug in the ground and covered at the top or midway down with a lid of bark. The earliest known prehistoric instrument, found always associated with the stamped pit in Paleolithic excavations, is the slung rattle, which

was shaken or hung from the ankle, arm or neck of the dancer. It consisted of several shaking pieces: nutshells, seeds, hooves, teeth or similar hard objects. The gourd rattle (a gourd containing such hard objects) became an important instrument in ritual and to mark time for dancing. Like other primitive instruments it was believed to possess magical power. As a nursery toy, its modern equivalent soothes and amuses children. Under the name maraca (*see* below) it is an important instrument in the modern Latin-American dance orchestra.

Primitive Drums.—Next in chronological order are the slit drum and the membrane drum found in Neolithic excavations. In its earliest form the slit drum was a hollowed tree trunk, the fashioning of the cavity giving the drum two distinct tones, one on each side of the opening. The original instrument was stamped upon, rammed with long sticks or struck with cudgels, the tone produced being of considerable resonance and carrying power. Existing specimens measure up to 20 ft. in length and 7 ft. in width. The size of the instrument diminished as it developed. In the modern orchestra, the slit drum is found in the form of the Chinese wood block, a small percussion instrument with a clear, penetrating tone.

The drum became indispensable in primitive life. Credited with powers of magic and having numerous other functions, it was held to be the most sacred of instruments, and was therefore developed in several forms. The early membrane drum, which was struck with the bare hands, consisted of a section of hollowed tree trunk covered at one end with reptile or fish skin. Later, the end was covered with the skin of hunted game or of cattle, and sticks were used for striking the drum, which was played in an upright or slanting position, according to its length. The double-headed drum came later, and, with the advent of pottery, the clay drum, an earthenware vessel taking many shapes—goblets, cups, etc. Various methods were used for fastening the skins, some of which are still in use. The skin might be secured to the single-headed drum with pegs, nails, glue, buttoning or neck lacing with cord, while the skins of the double-headed drum were directly cord-braced (*i.e.*, laced through the holes of the skin).

Each of the early civilizations furnishes evidence of the development of the drum. A vase from Adab (*c.* 3000 B.C.) and other objects found in Mesopotamia at this period illustrate the shallow or frame drum and small cylindrical drums being played in horizontal and vertical positions. A drum (nailed head) as tall as the two players is depicted on a Sumerian vase of the same period. Early Egyptian artifacts show a drum with the skins stretched by a network of thongs, and provide evidence of the use of clappers and concussion sticks. Struck together, the latter were used to scare birds, as a musical instrument to accompany ritual dances and to provide rhythm for work in the fields and at the stamped wine press. An ancient tomb of the Egyptian kings in the catacombs of Eleithya, near Thebes, depicts a group of performing women, one of whom holds a curved concussion stick in each hand.

The origin of the hourglass drum is obscure. A waisted drum, narrower in the middle than at the ends and little longer than it is wide, is seen on one of the Bharatat reliefs, the oldest Indian temple reliefs (2nd century B.C.). The instrument is suspended from an ape's shoulders, and is being played with two sticks by the animal. The Indian clapper drum (*damaru*), a small drum which is similar in shape to the hourglass, has one or two cords fixed in such a manner that they strike the skins when the instrument is moved to and fro. An hourglass drum with movable pitch (*kalengo*) is still used in Nigeria. Leather thongs stretch from end to end, connecting the two membranes. The drum is held in the hand or under the arm, the player squeezing the cords or releasing the pressure to alter the pitch. The *kalengo* is played with the hands or a curved flat-ended stick. It is used by the Yoruba for their *Sakara* dances and signaling. Skilled players are able to make the drum follow their own tonal language and to interpret it. The manufacture of an important drum involves considerable ceremony, and its use is observed with time-honoured customs. In east Africa, the drum is considered holy and the drumyard a place of refuge. The coronation drums are struck with sticks made of human tibias, and offerings such as cattle are made to the royal instruments. Complex rhythms characterize the playing of African drums.

The barrel and shallow nail drum are associated with India and the far east. The wooden frame of the shallow Chinese drum is lacquered red, as a symbol of happiness, and the skins emblematically adorned with the dragon and phoenix. The drum is normally suspended on a stand, the player striking the centre with leather-knobbed sticks, named male and female. A spring is fixed inside certain types of shallow drums of Chinese origin. The spring strikes the inner side of the skins when the outer surfaces are struck. Giant drums were used in Asia in war. The drums and players (who were madmen recruited from prisons) were secured to wagons drawn by oxen, and placed at the head of battle formation. The frenzied performers pounded their instruments unceasingly with heavy clubs and whips. The strength of the noise from the opposing sides often proved a decisive factor in the conflict. The giant drum of the Chinese called *Hiuen-Kou* is said to have been invented for use in the imperial palace in 1122 B.C. This instrument was a barrel drum with nailed heads, upward of four inches in diameter and depth. It oscillated on a specially prepared stand and had a smaller drum on each side.

The wooden fish (China and Japan) is a form of slit drum expertly carved to resemble a mythical fish. The instrument is hollowed out through a ventral slit representing the creature's open mouth, lacquered red and gold and is struck with a heavy painted stick similarly coloured. It is beaten to attract the attention of the divinity, and is tolled in slow tempo by mourners at a funeral service. In modern times the wooden fish is found in many sizes in western orchestras under the name of temple block. It often replaces the coconut shells used to imitate the sound of

horses' hooves, and it adds humour to numerous situations on film and radio such as the sound of a popping champagne cork.

The *tablā* player, who is a prominent musician in Indian chamber music, performs on two drums, the *bayan* and *daina*. The *bayan* is a small kettledrum (metal shell) with skin stretched by means of leather thongs. The *daina* has the shape of a truncated cone, is made of wood and is painted in multicoloured stripes. The skin is stretched by leather thongs which are tightened by movable wooden dowels. Circular patches of a substance resembling hard rubber are affixed to the vellum of each drum. The skins are struck with the hand, finger tips, or side of the thumb and vibrated by friction, the ingenious rhythms being enhanced by the different tones obtained from various parts of the vellums. A skilled *tablā* player ranks as a virtuoso. Nakers is the name given in medieval times to small hand-drums with bowl-shaped bodies made of metal —precursors of the orchestral timpani. *Naqqāra* is the Arabic name for similar instruments, which came to Europe as the result of the Crusades. Nakers are often mentioned in medieval literature, and depicted in the Louterell Psalter of the early 14th century, where a pair is seen suspended in front of the player by a strap round the waist, a stick being held in each hand. In Holbein's wood engraving "Dance of Death" Death is seen beating a drum with a thighbone. The instrument is similar in appearance to and positioned like the medieval naker.

Bongoes are small Cuban drums, bucket-shaped wooden vessels with strong vellum heads which are struck with the fingers and thumb. They form part of the Latin-American orchestra and modern dance bands and consist of a pair of drums of different size and pitch, normally tuned a fifth apart. The instruments are fixed together, and held between the knees or affixed to a stand. Timbales, the French name for kettledrums, is a term loosely applied to instruments in the form of large bongoes in the Latin-American orchestra. They are a pair of drums mounted on a stand and played with sticks. Often the player also performs on a cowbell or paila; the latter was originally an upturned bucket but was later made in the form of a metal plate. (*See* DRUM; MUSIC, PRIMITIVE; MUSIC IN ANCIENT CIVILIZATIONS.)

Percussion Groups.—Marrow bones and cleavers is the name given to the traditional music of the butchers of England and Scotland, for which the meat vendors of the old Clare market, London, were long famous. The players produced a musical effect from their implements by a skilful manipulation of their knives (cleavers), and an assortment of marrow bones. A complete octave, rendering the effect of a peal of bells, was produced from the cleavers, and rhythmic features were provided by striking the bones and also drums. Important weddings brought these players considerable remuneration both for their attendance and their abstention. On being informed that the "orchestra" intended to serenade the couple, the father of the bride would seldom refuse the gratuity in advance to escape the infliction. The marrow bones and cleavers can be observed in use in plate VI of Holbein's series "The Wedding of the Industrious Apprentice to His Master's Daughter" (1538). An early use of percussion instruments in domestic music making is seen in Bottom's remark in *A Midsummer Night's Dream* ". . . I have a reasonable good ear in music. Let's have the tongs and the bones." A domestic instrument associated with the marrow bones and cleavers was the saltbox. It was beaten with a rolling pin in such a manner as to produce varying sounds, and was used to provide a rhythmic accompaniment to an instrumental ensemble. The verse in Bonnell Thornton's burlesque "Ode to St. Cecilia's Day" (1763), which so amused Dr. Johnson, describes the method of performance.

> In strains more exalted the salt-box shall join,
> And clattering and battering and clapping combine;
> With a rap and a tap while the hollow side sounds,
> Up and down leaps the flap, and with rattling rebounds.

The steel band originated in Trinidad; the instruments consisted at first of trash can (dustbin) lids, and later, of oil drums. It is believed that these domestic appliances replaced various bamboo instruments, and that the authorities prohibited their use on feast days in view of their possible use as weapons during periods of unrest. Dents are skilfully fashioned in metal receptacles of varying size, and the base of the depression struck with a mallet. The pitch of the note is determined by the diameter and depth of the indentation. The steel band in commercial entertainment has a considerable musical attraction, the range of the instruments covering four chromatic octaves.

Bell Instruments.—The Turkish crescent (*chapeau chinois* or jingling johnny) is an instrument introduced into the military bands of Great Britain and elsewhere about 1800, at the time of the popularity in western Europe of Janissary music. The crescent is an upright pole surmounted by a tent-shaped construction and metal headpiece, composed of a crescent and other symbols, from which points and elsewhere on the pole hang small bells and

jingles. Plumes made from horsetails further ornament the instrument, the bells and jingles of which are shaken in rhythm.

The sistrum is an instrument of percussion of definite pitch (occasionally found in Italian scores) consisting of a series of small mushroom-shaped bells, mounted in pyramid-fashion on a handle. The compass of the instrument ranges from one to three octaves, with the bells mounted diatonically in a single row, or chromatically in two rows. (*See* SISTRUM; GLOCKENSPIEL; BELL.)

The tubaphone was a popular solo instrument in the military band repertoire during the early part of the 20th century. It consisted of a series of short metal tubes arranged in a frame in two rows. Similar in design and sound to the orchestral glockenspiel, it was played in the same manner.

The jingles are a spray of bells, or metal pieces, smaller than the normal sleigh or harness bells.

Percussion Instruments in the Orchestra.—"Slap-Stick" is a device used in the orchestra to produce the sound of the crack of a whip and consists of two pieces of wood, joined in a V-shape by hinging at the base, or partway up to form a handle.

Maracas are Latin-American percussion instruments used in pairs in the rumba band. Each maraca is a gourd, or substitute, fixed to a handle filled with dried seeds which rustle when the instrument is shaken, or alternatively produce a clicking sound when the gourd is tapped with the forefinger. (*See* above). Claves are round sticks of hardwood six to eight inches in length, descendants of the primitive concussion sticks (*see* above). In the Latin-American dance orchestra rhythm is marked by the claves which the player strikes in a recurring pattern. One piece of wood, held over the upturned fingernails of one hand, is struck with the other, held lightly in the manner of a drum stick. Bones are a percussion instrument used in the 19th-century British or American Negro minstrel band. Two pieces of a rib bone of an animal are held between the fingers and clicked together. The cabaça is a Latin-American instrument consisting of a calabash shell surrounded with a network of beads. The handle of the cabaça is held in the right hand with the bowl of the instrument resting in the palm of the left hand. Rotation of the handle causes the resonant bowl to turn within its network of beads, producing a gentle rasping sound.

The guiro (known also as scraper or reso-reso) is a calabash gourd, or short length of bamboo stem into which is plowed a series of deep grooves in regular formation. Sound is produced by drawing over the grooves a thin strip of bamboo, or similar rigid object. Stravinsky wrote a part for the "guero" in the original score of *Le Sacre du printemps* but later deleted it. The guiro forms an integral part of the modern rumba band.

PERCY, a family whose deeds are prominent in English history. It was founded by WILLIAM DE PERCY (*c.* 1030–96), a follower of the Conqueror, who bestowed on him a great fief in Yorkshire and Lincolnshire. The register of Whitby abbey, which he founded anew, and in later days the heralds, were responsible for exaggerating the origin and pedigree of the family. By Emma, daughter of Hugh de Port, a great Hampshire baron, William was father of several sons, of whom ALAN the eldest succeeded him. His grandson WILLIAM (d. 1175) was the last of the house in the direct line, and left two daughters and coheiresses, Maud countess of Warwick, who died childless, and Agnes. Agnes de Percy had married Jocelin, brother of Queen Adelaide, second wife of Henry I, and from this marriage descended the second house of Percy (which name it assumed), till its own extinction in the male line five centuries later (1670). By it was brought into the family the great Petworth estate in Sussex, which Jocelin had obtained from his sister. His son RICHARD (*c.* 1170–1244) was one of the 25 barons appointed to enforce the observance of Magna Carta and in 1216 was an active supporter of Louis of France against King John.

HENRY DE PERCY (1273–1314) was one of Edward I's most active agents in the subjugation of Scotland until the success of Robert Bruce drove him out of Turnberry castle, and made him withdraw into England. Summoned to parliament as a baron in the time of Edward I, he later, as one of the lords ordainer, supported the baronial opposition to the personal rule of Edward II. Hitherto the family had been mainly connected with Yorkshire, but Henry gave its fortunes a new direction by his purchase of lands in Northumberland from Antony Bek, bishop of Durham, among them the great lordship of Alnwick, which became the principal seat of the family. Henceforth the Percys, now the greatest landowners in Northumberland, became the principal guardians of the northeastern border against the Scots, and successive members of the family served regularly as wardens of the marches.

Henry's son, another HENRY (*c.* 1299–1352), did splendid service to his sovereign by defeating and taking prisoner David II, king of Scotland, at the battle of Neville's Cross (1346).

To him succeeded his son, another HENRY PERCY (1322–1368), a feudal baron like his predecessors, who fought at Crécy during his father's lifetime and whose brother THOMAS PERCY (1333–1369) was bishop of Norwich from 1356 to 1369. Henry's son, HENRY PERCY, 1st earl of Northumberland, father of the famous Hotspur, SIR HENRY PERCY (*q.v.*), was killed at Bramham Moor in 1408, his title and estates being forfeited after his rebellion in 1405. Henry V formally restored them in 1416 to this earl's grandson, HENRY (1394–1455), then a prisoner with the Scots, whose liberation he procured. For the later history of the family *see* NORTHUMBERLAND, EARLS AND DUKES OF. (C. D. R.)

BIBLIOGRAPHY.—E. B. De Fonblanque, *Annals of the House of Percy* (1887), and G. Brenan, *History of the House of Percy,* W. A. Lindsay, ed. (1902), both somewhat adulatory; Surtees Society, vol. 117, *The Percy Chartulary* (1911); Northumberland County History Committee, *History of Northumberland* (1893–1940); W. Dugdale, *The Baronage of England* (1675); G. E. C(okayne), *Complete Peerage,* revised ed., vol. ix and x (1936, 1945).

PERCY, SIR HENRY, called HOTSPUR (1364–1403), eldest son of Henry, 1st earl of Northumberland, was born on May 20, 1364. He saw active service when he was 14 at the siege of Berwick. After 1384 he served almost continuously as warden of either the East or the West March toward Scotland, and his zeal in border warfare won him the name of Hotspur from his opponents. In popular story and ballad he is known as one of the heroes of Otterburn or Chevy Chase. In the summer of 1388 the Scots sent a small body under the earls of Douglas, March, and Moray to invade Northumberland. The earl of Northumberland dispatched his sons Sir Henry (knighted in 1377) and Sir Ralph against the enemy. In hand-to-hand fighting before the walls of Newcastle, Douglas is said to have won Hotspur's pennon, which he swore to fix upon the walls of Dalkeith. The Scots then retreated to Otterburn where Hotspur, bent on recovering his pennon, attacked them on Aug. 19. Douglas was slain in the battle, though not (as is stated by the chronicler Thomas Walsingham) by Hotspur's hand. Hotspur was captured by Sir John Montgomerie, and his brother Ralph by Sir John Maxwell. Hotspur was released on the payment of a heavy ransom, to which Richard II contributed £3,000.

In July 1399 Hotspur and his father were the first magnates to join Henry of Lancaster (afterward Henry IV) on his landing in England, and played an important part in his successful usurpation. They were well rewarded for their support. Hotspur was appointed warden of the East March and captain of Roxburgh Castle, and received a series of offices and grants which made him virtual governor of northern Wales. With the young prince, Henry (afterward Henry V), he led the Welsh campaign of 1401, and in May was able to report considerable success in pacifying the North Welsh, and the recovery of Conway Castle. In the autumn of 1402 a Scots invasion of northern England led by the earl of Douglas was met by Northumberland and Hotspur, and the Scots were heavily defeated at Homildon Hill (Sept. 14). Thereafter the Percys became, in the words of the chronicler Adam of Usk, "too much puffed-up," and their relations with the king worsened. Roxburgh had already been taken from Hotspur in March 1402 and given to the earl of Westmorland. In disputes over the captives taken at Homildon Hill, the king refused to allow Hotspur to

retain Douglas as his personal prisoner. Nor would Henry permit him to ransom his brother-in-law, Sir Edmund Mortimer, from the hands of the Welsh rebels. Financial grievances inflamed these differences. The Percys were unable to secure payment of much of the money owed them for their charges in the north and in Wales, and were impatient of Henry's genuine financial difficulties. By 1403 it was clear that the king could not be so easily dominated as they had hoped, and, with the precedent of king-making still fresh, they determined to replace him on the throne.

In July 1403 Hotspur raised the standard of rebellion in Cheshire, where Richard II had won for himself a special loyalty. Henry was accused of having broken his promises, of murdering Richard II, and of excluding from the throne Richard's legitimate heir, the young earl of March, to whom Hotspur was related through his wife, Elizabeth Mortimer. The king's speedy action prevented Hotspur's occupying Shrewsbury and joining his Welsh ally, Glendower, and on July 21, 1403, Hotspur, accompanied by his uncle, Thomas Percy, earl of Worcester, and the earl of Douglas, with a force of Cheshire men, was forced to give battle outside Shrewsbury. Hotspur was killed, the earls of Douglas and Worcester were captured, and the rebel army dispersed. Worcester was executed two days later. Percy's body was buried at Whitchurch, about 16 mi. N of the battlefield, but was disinterred two days later to be exhibited in Shrewsbury. The head was cut off and fixed on one of the gates of York.

PERCY, THOMAS (1729–1811), English man of letters and bishop of Dromore, whose ballad collection *Reliques of Ancient English Poetry* (1765) stimulated research into ballad poetry and inspired the romantic movement. He was born at Bridgnorth, Shropshire, April 13, 1729. He went to Christ Church, Oxford, and held livings at Easton Maudit (1753) and Wilby (1756), both in Northampton, for many years. In 1763 he edited the poems of the earl of Surrey and published *Five Pieces of Runic Poetry From the Islandic Language*. The *Reliques* were based on an old manuscript he rescued from a friend's house, where parts of it had been used to light the fire. He edited them at William Shenstone's suggestion and, although some doubted their authenticity and many scoffed at their primitive style, they became increasingly popular and profoundly influenced Scott, Wordsworth and Coleridge. The standard edition is by H. B. Wheatley (1876). In 1770 Percy published *Northern Antiquities*, a set of translations including one (from a Latin version) of the Icelandic *Edda*, which thus became available to English readers for the first time. In his preface he makes a scholarly distinction, unusual for his period, between the various branches of the Celtic and Teutonic peoples. His *Ancient Songs*, chiefly on Moorish subjects, translated from Spanish, were edited by D. Nichol Smith (1932).

Percy became domestic chaplain to the duke of Northumberland (1770) and, through his influence, dean of Carlisle in 1778 and bishop of Dromore in Ireland in 1782. He died there on Sept. 30, 1811.

See A. C. C. Gaussen, *Percy, Prelate and Poet* (1908); *The Percy Letters*, ed. by D. Nichol Smith and C. Brooks, 5 vol. (1944–57).

PERDICCAS, the name of three kings of Macedonia who reigned respectively in the 7th century B.C., *c.* 450–413, and 365–359, and of one of Alexander the Great's generals (*c.* 365–321); the last is the subject of this article.

Son of Orontes and a descendant of the princes of Orestis, one of the Macedonian provinces, Perdiccas served with distinction in Alexander's campaigns. At the time of Alexander's death (323) he had acquired a leading position at the court and in the army. He led the aristocratic party which supported the claim of the unborn child of Roxana, Alexander's widow, to the succession. After the compromise under the terms of which a joint kingship and a division of the powers of regency were arranged, Perdiccas exercised a wide authority in Asia as "supreme general" and soon began to act as if he meant to make himself master of the whole empire. This attempted usurpation was strongly resisted by the regional governors Ptolemy in Egypt and Antigonus in Phrygia and by Perdiccas' colleagues in the regency, Craterus and Antipater. In 322 Perdiccas conquered Cappadocia and installed as satrap his most reliable and efficient subordinate, Eumenes (*q.v.*) of Cardia. Antigonus refused obedience and fled to Europe, where he persuaded Antipater and Craterus that Perdiccas must be destroyed. Leaving Eumenes to hold Asia Minor against Craterus and Antigonus, Perdiccas marched against Ptolemy. But when he failed to force the Nile mutinous officers led by Peithon and Seleucus murdered him (321).

See F. Geyer in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, vol. xix, 590–614 (1937). (R. H. Si.)

PERDIX (also known as Polycaste), in Greek mythology, a woman of Athens, whose son, Talos, studied with her brother, Daedalus. The boy invented the saw and the draftsman's compass, whereupon Daedalus in an envious rage threw him from the Acropolis. Perdix hanged herself, and the Athenians dedicated a shrine to her beside the Acropolis. According to Ovid (*Metamorphoses*), Perdix was the name of the boy; on his fall he was changed into a partridge (Gr. *perdix*) by Athena. (T. V. B.)

PEREDA, JOSÉ MARÍA DE (1833–1906), Spanish writer, the acknowledged leader of the modern Spanish regional novelists, a realist in the tradition of Cervantes and the picaresque writers. Born at Polanco near Santander on Feb. 6, 1833, of a family noted for its fervent Catholicism and its traditionalism, Pereda looked an authentic hidalgo. His first literary effort was the *Escenas montañesas* (1864), starkly realistic sketches of the fisherfolk of Santander and the peasants of the Montaña. There followed other sketches and early novels of pronounced controversial spirit, such as *El buey suelto* (1878), a counterpart to Balzac's thesis in *Petites misères de la vie conjugale; Don Gonzalo González de la Gonzalera* (1879), a satire on the revolution of 1868 and a eulogy of the old patriarchal system of government; and *De tal palo tal astilla* (1880), a protest by a rigid Catholic against the liberal religious tendencies advocated by his friend Benito Pérez Galdós in his novels *Doña Perfecta* and *Gloria*.

With the exception of *Pedro Sánchez* (1883), where Pereda describes the disillusion of a 19th-century Gil Blas from the Montaña in the troubled political arena of the capital, and *La Montálvez* (1888), a satirical description of Madrid society, all his novels have a Montaña background.

Pereda's best work, one of the finest Spanish novels of the 19th century, was *Sotileza* (1884), an epic of the Santander fisherfolk and a genuine novel of customs. The author's avowed aim was to paint the life of the old Santander fisherman with its virtues and its defects, and he has done this with great sympathy and realism. A masterpiece of characterization is the portrait of Sotileza, the haughty and enigmatic fishergirl.

Pereda resembles Thomas Hardy in his regionalism and Dickens in his love for the "good old days," but in his virile realism, tinged with a fund of human sympathy, he is thoroughly Castilian. He was not a good psychologist nor a good story-teller, but he possessed the gift of creating human characters, particularly of the humbler variety, and, with his mastery of rich and flexible language, he excels, above all, as a painter of nature, in all its aspects. Pereda died at Santander on March 1, 1906.

PÈRE DAVID'S DEER, a large, rare Asian deer, unknown in nature within historic time, that differs from all other deer in shedding its antlers twice, rather than once, each year. It is *Elaphurus davidianus*, the only species of its genus. Presumably its original home was in northern China, and fossil remains have been found in Japan. It is now found only in confinement on estates and in zoological gardens. This unusual deer stands more than three and one-half feet at the shoulder. The pelage is tawny red in summer, becoming uniformly grayish in winter; the under parts, rump, area around the eyes, and muzzle are whitish. Fawns are spotted with white. The antlers, up to three feet long, fork shortly above the burr, the front prong branching once and the

hind prong extending backward, unbranched. The long, bushy tail, reaching the hocks, is another unique feature of this deer.

Description of this deer was based on specimens obtained in 1866 through a French missionary, Père Armand David, from the Imperial Hunting Park 3 mi. S of Peking. The park was enclosed originally by a 45-mi. brick wall. Fortunately, before the Peking herds were destroyed around 1900, translocations to various European estates had already been made. The largest herd resides at Woburn Abbey, Bedfordshire, Eng. *See* also DEER.

PEREGRINATIO ETHERIAE (PILGRIMAGE OF ETHERIA), the anonymous incomplete Latin account of her travels in the Middle East written by a nun from western Europe for her colleagues at home toward the end of the 4th century A.D. It is important for the information it gives about religious life and the observances of the church year in the localities visited, which include the chief holy places of the Old and New Testaments in Egypt, Palestine and Syria. There is a detailed description of the daily and annual liturgical activities at Jerusalem. Discovered in 1884 by J. F. Gamurrini in an 11th-century manuscript at Arezzo, the account was first attributed to Silvia, the sister of Rufinus, but in 1903 it was shown that the author was a Spanish nun called Etheria or Aetheria (variants are Egeria and Eucheria). The date of the account, which depends on internal evidence, lies between 363 and 540; most scholars agree that within this period the most likely date is during the last years of the 4th century. *See* also CHURCH YEAR: *Jerusalem.*

BIBLIOGRAPHY.—Edition with French trans. by H. Pétré in *Sources chrétiennes* (1959); Eng. trans. by M. L. MacLure and C. L. Fettoe (1919). *See* also A. Bludan, *Die Pilgerreise der Aetheriae* (1927).

PEREGRINUS PROTEUS (2nd century A.D.), Greek Cynic philosopher celebrated for his spectacular suicide. According to Lucian, whose letter "On the Death of Peregrinus" is the main source of information about him, he was suspected of parricide in his youth and had to emigrate from his native city of Parium in Mysia. He later took up residence in Palestine, but his influence in the Christian community there led to his being arrested. On his release he left Palestine and became estranged from the Christians. In Egypt he met the Cynic philosopher Agathobulus, whose views he combined with what he had learned from Christianity (*see* CYNICS). He next went to Rome, but was expelled by the prefect for insulting the emperor Antoninus Pius. After leaving Rome he went to Greece, where he was at first well received, but compromised his popularity by disparaging the public benefactor Herodes Atticus. He then announced his intention of cremating himself and finally did so on a funeral pyre during the Olympic Games of A.D. 165, in the presence of many spectators, among whom was Lucian.

Though Lucian's account of Peregrinus represents him as an opportunist and an exhibitionist, not all ancient authors agree, and modern scholars are inclined to think of him as sincere, however abnormal, in his enthusiasms. The influence of Oriental religion is suggested by the manner of his death. He assumed the name Proteus himself, in allusion to the ever-changing Proteus of mythology.

See Lucian, "The Death of Peregrine," *Works*, vol. iv, Eng. trans. by H. W. and F. G. Fowler (1905); also K. von Fritz, "Peregrinus," Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, Halbband 37 (1937).

PEREIRA, NUNO ÁLVARES (1360–1431), called THE HOLY CONSTABLE, one of the outstanding Portuguese military leaders of his time, victorious throughout a long career of warfare, was born at Bonjardim, near Sertã, on June 24, 1360, the illegitimate son of Álvaro Gonçalves Pereira, prior of the Order of the Hospital of St. John of Jerusalem. On the death of King Ferdinand (October 1383), he came forward at once as a supporter of the master of Avis, the future King John I (*q.v.*), in defense of Portugal's independence against the claims of Ferdinand's heiress Beatriz, who had been married to John I of Castile. His talent soon became manifest, and it was his army that defeated the Castilians in the Battle of Atoleiros (April 6, 1384). Further heroic actions won him appointment to the office of constable of the kingdom in 1385. The victories at Aljubarrota (Aug. 14, 1385) and at Valverde (Oct. 15 or 16), which demonstrated Portugal's military superiority over Castile and assured the nation's independence, were largely due to his resolute conduct in leadership and in action; and he took part in the subsequent fighting against the Castilians until the peace of Oct. 30, 1411. Finally he gave all his support to the expedition that captured Ceuta from the Moors in 1415. His sovereign heaped honours upon him, giving him the countship of Ourêm, Barcelos, and Arraiolos, with extensive lands and properties. By his wife, Leonor de Alvim, the constable had a daughter, Beatriz, who was married to John I's legitimated son Afonso and so became the ancestress of the house of Braganza (*q.v.*). Pereira, who had had a Carmelite house built in Lisbon in fulfillment of a vow, entered it himself as Friar Nuno de Santa Maria in 1423. He died there on April 1, 1431. Pope Benedict XV beatified him on Jan. 23, 1918. (V. R. R.)

PEREIRA DE SOUZA, WASHINGTON LUIZ (1869–1957), president of Brazil, was born at Macaé, Rio de Janeiro, Oct. 26, 1869. He was reared in and identified politically with the state of São Paulo. A career politician for over 30 years, he held numerous public offices, including those of mayor of the city of São Paulo and of state governor (1920–24). His most lasting contribution as president was the initiation of an ambitious highway construction program, which was expanded by his successors. Under the political system of the time his election as president in 1926 had been assured by his predecessor. However, in the revolution of 1930, led by Getúlio Vargas, the old system collapsed. Pereira de Souza was deposed and exiled to Europe three weeks before completing his term. He was thus the last president of the so-called "old republic." He returned to Brazil in 1947 and died in São Paulo on Aug. 4, 1957. (R. E. P.)

PEREKOP, an isthmus in the Ukrainian Soviet Socialist Republic, U.S.S.R., between the Karkinitski Gulf of the Black Sea and the Sivash, or Putrid Sea, which links the Crimea to the mainland. At its narrowest it is only four miles across. As the only land route to the Crimea, until the rail causeway across the Sivash was built in 1873, the isthmus for long had great strategic significance. An earthen bank and ditch across it at the narrowest part are of prehistoric date and are believed to have given the name of Taphros ("ditch") to a nearby Greek colony. In the 13th century Perekop, with the rest of the Crimea, passed to the Tatars. Their khan, Mengli Ghirai, in the late 15th century renewed the dike and erected fortifications, including a new fort, Or-kapu, on the site of Taphros, where the village of Perekop now stands. The isthmus has been the scene of many battles, notably the Russian onslaughts in 1736 under B. K. Minikh, in 1738 under P. P. Lassi, and in 1771 under Prince V. M. Dolgoruki. In 1920 the Red Army under M. V. Frunze defeated Gen. P. N. Wrangel there, and during the German advance of 1941 and retreat of 1944 there were fierce engagements at Perekop. A road, a railway, and an irrigation canal now enter the Crimea by the isthmus.

(R. A. F.)

PERETZ, ISAAC LEIB (1852 or 1851–1915), Yiddish and Hebrew man of letters, especially remembered for his sketches of Hasidic life whose rich spirituality he portrays with sympathy and understanding, was born in Zamosc, Pol., on May 18, 1852, or May 20, 1851. A brilliant student, he acquired a traditional Jewish education before turning to secular studies partly under the guidance of his father-in-law. A disciple of the movement of enlightenment, *Haskalah*, he wrote poems in Yiddish and Hebrew criticizing Jewish customs, meanwhile earning a livelihood as an attorney at law. Compelled to leave his native town in 1889 because of a conflict with the authorities, he became a clerk in the offices of the Jewish congregation in Warsaw, but was imprisoned for some months in 1899 for socialist activities. During the last

ten years of his life he became the recognized leader of the Yiddishist movement, whose aim—in opposition to the Zionists—was to create a complete cultural and national life for Jewry in the Diaspora with Yiddish as its language. A prolific and versatile writer of poems, short stories, dramas, allegories, satires, humourous sketches and *feuilletons*, Peretz was partly instrumental in raising the standards of Yiddish literature to a high level. Although scathingly critical of the traditional modes of Jewish life and the bitter inequalities of the wider social order, he also recognized the nobility of spirit so frequently shrouded by a poverty-stricken and ugly environment. His stories, which are largely concerned with humble lives, are episodic but keenly penetrating, while his sympathy for the poor and friendless is moving and sincere. He died in Warsaw on April 3, 1915.

PEREYASLAV-KHMELNITSKI (formerly PEREYASLAV), a town in Kiev *oblast* of the Ukrainian Soviet Socialist Republic, U.S.S.R., stands on the right bank of the river Trubezh, 6 mi. (10 km.) above its confluence with the Dnieper and 45 mi. (72 km.) SE of Kiev. One of the oldest Russian towns, Pereyaslav (sometimes known as Pereyaslav Russki or Pereyaslav Yuzhni) was first mentioned in 907. In the 11th century the town flourished and was made the seat of a princedom by Yaroslav the Wise for his third son. There were princely and episcopal kremlins at that time, and the commercial town was enclosed by ramparts 3,500 yd. (3,200 m.) long, parts of which survive. In 1096 the town was besieged by the Cumans (Polovtsy) and in 1239 it was sacked by the Tatars. Thereafter the town passed to Lithuania and later to Poland but, after the failure of a Cossack uprising in 1648, the Cossacks under Bogdan Khmelnitski (Bohdan Chmielnicki; *q.v.*) met at Pereyaslav in 1654 and acknowledged the supremacy of the tsars. After the Revolution the town's name was expanded to honour Khmelnitski. Modern Pereyaslav (1959 census, 14,361) is a small market town of only local significance. (R. A. F.)

PÉREZ, ANTONIO (1540–1611), secretary of Philip II of Spain, whose career presents one of the earliest examples of a now familiar phenomenon, that of a man who is driven to treason by a system of political absolutism in which he himself has played a prominent part. He was born at Madrid, the illegitimate son of Gonzalo Pérez, secretary of the emperor Charles V, and was legitimated in 1542. Charming, intelligent, and, through his father, well connected, Pérez quickly rose in the service of Philip II, becoming the king's secretary (1568) and secretary of several of the royal councils. A long line of historians, dramatists, and novelists have speculated on Pérez's supposed liaison with Doña Ana de Mendoza, the one-eyed princess of Eboli and widow of Philip's favourite, Ruy Gómez de Silva, although it is very unlikely that their relationship was anything but a political alliance.

The upstart secretary was hated by many of the grandees and by his rivals in the Spanish civil service. The king's favour was unstable, and to safeguard himself, Pérez intrigued with all parties: with Philip II's half brother Don John of Austria and his secretary, Juan de Escovedo, against the king; with the king against Don John; perhaps even with the Netherlands rebels against both. When Don John, then governor-general of the Netherlands, sent Escovedo to Spain in 1577 to plead for his plan to invade England and liberate and marry Mary Stuart, queen of Scots, Pérez feared the exposure of his own intrigues. He persuaded the suspicious king that Escovedo was Don John's evil genius and was plotting treason. The king gave his consent to the murder of Escovedo and Pérez organized his assassination on March 31, 1578.

Philip II never forgave Pérez for having forced his hand. On July 28, 1579, he had Pérez and the princess of Eboli arrested. For eleven years, Pérez remained in prison and all efforts to extract a full confession and all incriminating documents from him failed. In April 1590 he escaped from Madrid to Aragon and placed himself under the protection of the Aragonese courts. Now, for the first time, he accused the king of the murder of Escovedo. Philip thereupon tried to have Pérez handed over to the Inquisition, but the populace of Saragossa twice rioted (May and September 1591) and prevented this move. Philip considered it rebellion and sent a Castilian army into Aragon (October 1591).

Pérez fled to France in November. He spent the remainder of his life at the courts of France and England, carrying on his polemic against Philip II and contributing to the "black legend" about the king. After Philip II's death (1598), Pérez lost what little influence he had had. He failed to obtain a pardon from Philip III and died in poverty in Paris, on Nov. 3, 1611. His *Relaciones*, of which there are many editions, was published in 1598.

See G. Marañón, *Antonio Pérez*, 2 vol. (1947), abridged edition translated into English by C. D. Ley (1954); K. O'Brien, *That Lady* (1946), a typical novel on the subject. (H. G. KO.)

PÉREZ DE AYALA, RAMÓN (1880–1962), eminent Spanish novelist, poet, and critic, was born at Oviedo on Aug. 9, 1880. He studied at Jesuit colleges and the University of Oviedo, traveled widely, wrote poetry, and indulged in journalism. The ruin and suicide of his father made him turn to writing as a profession—so successfully that he was elected to the Royal Spanish Academy in 1928. A man of liberal, cosmopolitan outlook, Ayala worked for the establishment of the second republic and represented it as ambassador to Great Britain from 1931 to 1936. He lived in Argentina for some years, but returned to Spain in 1954. His first novels, more or less autobiographical and realistic, were *Tinieblas en las cumbres* (1907), *A.M.D.G.* (1910)—a grim picture of Jesuit education—*La pata de la raposa* (1912; English translation, *The Fox's Paw*, 1924), and *Troteras y danzaderas* (1913), a satirical presentation of Madrid literary and bohemian life.

Three short tragic *novelas poemáticas* (1916) marked the transition to Ayala's more stylized mature manner with its use of myth and symbolism. *Belarmino y Apolonio* (1921), by many considered his masterpiece, portrays with great comic force two rivals: the cobbler-philosopher whose preoccupation with language ultimately reduces him to silence, and the cobbler-dramatist, a garrulous extrovert. *Luna de miel, luna de hiel* (1923) and its sequel *Los trabajos de Urbano y Simona* (1923) describe a young couple's emergence from sexual innocence into maturity. His last major work, in two parts, *Tigre Juan* and *El curandero de su honra* (1926; Eng. trans., *Tiger Juan*, 1933), is a reworking of the Don Juan and honour themes. His intellectual power, literary craftsmanship, sensitive use of language, and fine ironical humour make him one of Spain's foremost novelists. He died in Madrid on Aug. 5, 1962.

See F. Agustín, *Ramón Pérez de Ayala* (1927); N. Urrutia, *De Troteras a Tigre Juan* (1960). (H. B. HL.)

PÉREZ DE HITA, GINÉS (1544?–1619?), Spanish writer, is known for his authorship of the *Historia de los bandos de Zegríes y Abencerrajes o Guerras civiles de Granada* (modern edition by P. Blanchard-Demonge, 1913–15), the first Spanish historical novel and last important collection of Moorish border ballads, which punctuate the narrative like the lyrics in contemporary pastoral novels. The chivalrous Abencerrages (*q.v.*) of the first part (1595), which depicts the political disintegration of the kingdom of Granada preceding its fall, established the stereotype of the romantic Moor of European literature; the second part (1619), describing the campaign of 1568–71 against the Moriscos, in which the author served, is marked by compassion for the vanquished and a generous anger at Christian excesses.

See P. Festugière, in *Bulletin Hispanique* (1944). (F. S. R.)

PÉREZ GALDÓS, BENITO (1843–1920), the greatest Spanish novelist since Cervantes. He was interested in the entire nation at a time when regionalism was prevalent; he looked forward to a more prosperous, free, and enlightened Spain. He revealed to Spaniards the meaning of their recent history and the forces which were making modern Spain, and also showed them their own national psychology through his masterly creation of a wide range of characters.

Born at Las Palmas in the Canary Islands, on May 10, 1843, Galdós went to Madrid in 1862 to study law, but soon abandoned

the university for journalism. His youthful articles showed cautious liberalism in politics and intransigent opposition to the intolerant religious trends of the times. The same attitudes appeared in his early novels, the first being *La fontana de oro* (1870).

Galdós saw that the Spain of the 1870s was the outcome of events of the Napoleonic Wars, an epoch neglected by Spanish historians. He began in 1873 to publish a series of historical novels —*Episodios nacionales*—which retold Spain's history from the Battle of Trafalgar (1805) to the death of Ferdinand VII (1833). For background material he used memoirs, old newspaper articles, and eyewitness accounts; thus his novels were vivid and accurate historically, and they achieved a great popular success. By 1879 he had completed two series—each of ten volumes—and he then renounced the historical novel for the contemporary scene.

He had already brought out four contemporary novels, beginning with *Doña Perfecta* (1876). In them the reforming spirit of his early period still prevailed. But after 1880 a new tone was struck, one of tolerant acceptance of Spain's idiosyncracies, of identification of the author with Spain, which he now chided benignly and admonished only indirectly for its faults.

The new series, somewhat influenced by French naturalism, began with *La desheredada* (1881) and reached its culmination with *Fortunata y Jacinta* (4 volumes, 1886–87), Galdós' masterpiece and one of the monuments of world literature. Galdós had become the novelist of Madrid, displaying a phenomenal knowledge of the city which is the epitome of all Spain, and he had also become the analyst of the Spanish character. The realism which dominated this period gradually admitted more and more elements of spirituality, at first questioning their value—*Ángel Guerra* (3 volumes, 1890–91)—later accepting the forces of the spirit as an integral part of reality—*Nazarín* (1895) and *Misericordia* (1897).

In 1892 Galdós produced *Realidad,* his first acted drama. Despite his denials, this work and his subsequent plays owed something to the current interest in Ibsen. Galdós never handled the dramatic form with the same sureness as the novel; his career as a playwright was one of alternating stormy successes, often for fortuitous causes—*e.g., Electra* (1901) which expressed the progressive, anticlerical mood of a section of Spanish opinion and so achieved a spectacular success for political rather than literary reasons—and of equally startling failures.

Galdós' financial difficulties caused him to resume the *Episodios nacionales,* beginning a third series in 1898. He went on to produce a fourth and part of a fifth series so that by 1912 he had written 26 more historical novels, bringing his account of Spanish history down to 1877 and retelling events of which he himself had been a witness. But this period of Galdós' life was one of gradual decline. Financial difficulties made him suspicious of others; political activity in the republican cause disillusioned him; finally, gradual loss of eyesight culminated in total blindness (1912). His last works, four plays (1914–18) and a novel (1915) show a withdrawal and a weakening of creative energy. He died in Madrid, Jan. 4, 1920.

PÉREZ JIMÉNEZ, MARCOS (1914–), military leader and president of Venezuela (1952–58), was born April 25, 1914, in Michelena. He became a professional soldier, receiving a commission from the Venezuelan Military Academy in 1934. His political activities began in 1944, and he took part in the *coups d'état* that overthrew the government on Oct. 18, 1945, and Nov. 24, 1948. After the second coup he served as a member of the military junta that ruled Venezuela. In December 1952 he became provisional president by designation of the armed forces—an appointment confirmed by the Constituent Assembly of 1953, which elected him to a five-year presidential term (1953–58). Pérez' administration continued the reformist programs standard in Venezuela since 1936, but failed to keep pace with increasing national needs. To maintain his regime he depended on popular apathy and armed forces support. Extravagance, corruption, police oppression, and mounting unemployment created conditions of dissatisfaction in the armed forces and among the people. Military malcontents attempted a *coup d'état* on Jan. 1, 1958, and the subsequent armed forces crisis enabled civilian discontent to find expression. Pérez was forced out of office on Jan. 23, 1958, and a civilian-military junta took control. He fled the country but was extradited by the U.S. in 1963 to stand trial for embezzling government funds. (R. L. GE.)

PERFUME, a composition whose fragrance gratifies the sense of smell and which is commonly associated with personal adornment. A perfume is difficult to define; the expression "a pleasant smell" is inadequate; a well-cooked dinner provides a pleasant smell but not a perfume in the generally accepted meaning of the word. More appropriate as a definition would be "a blend of materials, each with its own particular odour, resulting in one over-all and pleasant impression." It is preferable to use the word "blend" as distinguished from "mixture," which suggests something that might result from haphazard additions and might easily give an unpleasant odour impression. Expensive materials can be mixed in an inexpert manner to produce an odour with little appeal; on the other hand, quite pleasing perfumes can be made by the expert blending of inexpensive raw materials.

The nature of odour perception is not completely understood, although it is known that odorous substances must be capable of undergoing some degree of vaporization. An odorous chemical, whether liquid or solid, must change to the gaseous state and travel through the air to the nose. The sensory nerve system consists of (1) the receptor organ, where the odorous molecules are received; (2) the nerves, which transmit the response; and (3) the receiving area of the brain, which interprets the message. (*See* SMELL AND TASTE: *Sense of Smell.*)

Perfumery is commonly associated with handkerchief perfumes, toilet waters, cosmetics, and soaps, but perfumes are employed in many industrial products, including detergents, polishes, leather, rubber, etc. The psychological effect of a perfume is undeniable: it appeals to the senses in the same way as does a country scene, a fine painting, a pretty girl, or a piece of music.

HISTORY

The story of perfume touches on medicine, mythology, religion, and anthropology, and its raw materials have been gathered from all parts of the world. One of its earliest associations was with man's offering of pleasant odours to his gods by the burning of incense (the word perfume comes from the Latin *per fumum,* "through smoke"). The art of perfumery may well have been practised 25,000 years ago by the Indo-European races. Early Chinese records mention incense, and China's early and important contribution to perfumery was musk. Odorous products from 3,000 to 5,000 years old have been found. An Egyptian papyrus of 2000 B.C. refers to myrrh.

Perfumery appears to have been handed down from the Chinese, Hindus, Egyptians, Israelites, Carthaginians, Arabs, Greeks, and Romans. During the reign of the Pharaohs in Egypt, perfumes were used for a variety of purposes. The Bible makes numerous references to perfumery materials, including frankincense, myrrh, spicy balm, aromatic substances, musk, hyacinth, almonds, cinnamon, calamus, and cassia. Actual formulas for perfume are quoted in Exodus 30:23–25 and 30:34–35. From the 4th century B.C. perfumes were used in Greece in medicine and for pleasure. The mythology of the Greeks speaks of many fragrances and their scientists studied the art of perfumery. Interest in the essential oils was certainly shown in Egypt, Persia, and India. (Probably the first oil to be distilled was turpentine in the 4th or 5th century B.C.) Queen Cleopatra of Egypt used perfume to charm Julius Caesar and Mark Antony, and the Romans brought back many perfumery materials from Greece, Palmyra, and Arabia. Fats were used in ancient Greece and Rome to extract oils from roots and flowers. Perfumery was probably brought to Britain first by the Romans and again by the Anglo-Saxons, and in the Middle Ages returning crusaders reintroduced perfumes from the East. The first authentic description of essential oils is ascribed to Arnaldo de Vilanova, a Catalan physician, in the

period A.D. 1240–1311. From the fall of Rome to the Renaissance, the development of perfumery was mainly carried on by the Arabs and the Persians, who produced spices and gums and built up an important foreign trade. Between the 9th and the 12th centuries, the Arabs knew of distillation. The discovery of alcohol as a vehicle for perfumes was probably made in the 14th century and the first toilet water was based on rosemary ("Hungary water").

The revival of the arts during the Renaissance awoke a fresh interest in perfumery in Italy and France. Many books on perfumery were written during the 16th and the 17th centuries and the earliest formula for a lavender water is said to have been published in 1615. In the 17th and 18th centuries pharmacists and botanists and some early students of applied chemistry investigated essential oils and methods of distillation. Toward the end of the 18th century the production of essential oils and flower oils began to flourish in France. One of the first characteristic types of "flower water" was orange flower water introduced by the duchess of Neroli. This flower water, also known as neroli, forms an important part of eau de cologne and was introduced by Johann Marie Farina about 1725. From 1725 to 1850 perfumes changed from the fresh colognes to the more floral types. In 1850 the fancy or sophisticated perfumes of France made their appearance. Originally, they were based on tinctures of benzoin, vanilla, vetiver, patchouli, etc. The closing decades of the 19th century saw the advent of synthetic chemicals in perfumery and these made possible a greater variety of odour effects. Investigations since then have been associated with J. B. A. Dumas (1800–84), P. E. Marcelin Berthelot (1827–1907), W. A. Tilden (1842–1926), O. Wallach (1847–1931), and E. Charabot (1870–1938).

Another minor revolution came in the perfumery field when heavy flowery notes were modified with amyl (isoamyl) salicylate and methylnonylacetaldehyde. This vogue, still popular, was followed by perfumes with the accent on green, woody, and animal notes, as typified by sandalwood, vetiver, musk, and civet. Just before World War II, it became fashionable to accentuate the green notes; styralyl acetate (phenylmethyl carbinyl acetate) in particular found favour for this purpose. Great Britain is greatly influenced by Paris in its choice of perfumes, although certain floral types are very popular; *e.g.*, lavender, rose, and lily of the valley. In the Netherlands hyacinth and lilac are popular. About 1945, the French fashion houses brought in the "new look," a throwback to 1900, and perfumes likewise revived the powdery notes of the 1900 period—vanillin, orris, opopanax, etc. Spain and South America appear to remain loyal to their heavy spicy notes, while the best sellers in the United States have been based on the heavy exotic flowers idiom, although many of the famous French perfumes are also appreciated. (*See* also COSMETICS AND COSMETOLOGY: *Historical Development;* ESSENTIAL OIL: *History;* DISTILLATION: *Historical Note.*)

RAW MATERIALS

Perfumery raw materials may be divided into three main groups: (1) the essential oils and products isolated from these oils; (2) products of animal origin; and (3) synthetic chemicals.

The Essential Oils.—An essential oil (*q.v.*) consists of complex mixtures of volatile liquid and solid chemicals. These oils occur in various parts of plants and in some cases quite different types of oils are found in various parts of the same plant; *e.g.*, orange oil from the peel, petitgrain oil from the leaves, and neroli from the flowers of the orange tree. Typical examples are: *flowers* (jasmin, rose, mimosa, violet, ylang-ylang, orange blossom); *flowers and leaves* (lavender, rosemary, violet); *leaves and stems* (geranium, cinnamon, patchouli, petitgrain); *barks* (cinnamon, cassia); *woods* (sandalwood, cedarwood, rosewood); *roots* (vetiver, angelica); *rhizomes* (orris, ginger); *fruits* (orange, lemon, lime, bergamot); *seeds* (aniseed, nutmeg); *resinous exudations* (myrrh, benzoin, styrax).

It is uncertain whether the essential oils are present as a result of photosynthesis or whether they are simply by-products of plant metabolism. One earlier theory suggested that two simple chemicals, namely acetone and acetaldehyde, could be formed from carbon and water. These two chemicals can react to produce the important material citral and from citral many chemicals found in essential oils can be formed. A physiological synthesis from sugars has also been postulated. However, it now seems likely that acetic acid is the basic unit. Three molecules of this chemical may be converted biogenetically into senecioic acid with a loss of the carboxyl group. This provides the basic five-carbon isoprene unit. Fairly straightforward reactions can now be visualized which will yield the terpenes and derivatives such as myrcene, geraniol, and linalool. Evidence for alternative biological routes has also been found, *e.g.*, in the synthesis of the sterols.

Constitution.—All essential oils consist of a complex mixture of chemicals and this is true even in the case of those that contain a preponderance (*i.e.*, 80–90%) of one constituent. The great bulk of the constituents of the oils belong to a group of organic compounds known as the terpenes (*q.v.*), which include hydrocarbons of the formula $(C_5H_8)_n$ and their oxygenated derivatives. These compounds are peculiar in that most of them may be regarded as being derived by the fusion of isoprene units. Thus two isoprene units when fused yield the monoterpene (*e.g.*, limonene) structure, while three give the sesquiterpene (*e.g.*, cadinene) skeleton.

Hydrocarbons such as these can give rise to a large number of oxygenated derivatives; *e.g.*, alcohols and their esters, aldehydes and ketones. Some of the more important of these are geraniol, citronellol and terpineol, citral and citronellal, and, finally, camphor.

Besides the terpene family, a number of other organic compounds frequently occur in essential oils. These include a number of aliphatic aldehydes and also aromatic compounds including phenols such as eugenol.

Methods of Extraction.—The essential oils are separated from the plant by steam distillation and by extracting with volatile solvents such as benzene, lythene (a low-boiling, purified fraction of petroleum), and, in some cases, alcohol and butane. Two other methods are extraction with fats (enfleurage method) and a simple pressing of the oil from peels, as, for example, with lemon oil. Although certain oils will not withstand the somewhat harsh treatment of steam distillation, many oils (including most of the root, wood, bark, and leaf oils) are processed in this way.

In many cases the trees are cut down and the wood, etc., is taken to a local distillation unit, the oil obtained then being sent to central bulk depots before final distribution. For years the distillation units were crude vessels; the wood, leaves, etc., were placed in the vessels, water was added and the vessels were heated by fire. Water and oil distilled over and the oil was separated. The modern tendency is for processing plants to be erected where it is possible to inject steam into the vessel and where extraction can be performed under modern conditions.

Extraction by volatile solvent in most cases gives a bigger yield and extracts the oil in a more gentle fashion than does steam distillation. In some cases, leaves, petals, mosses, etc., are simply stirred in a large vessel with the solvent and, when the extraction is complete, the solution is passed through a filter and the solvent distilled away. In another method, batteries of percolators, each with a capacity of about 100 gal., are fitted with perforated trays on which the flowers are placed. At one end of the series is a solvent tank and at the other end a vacuum still. The solvent runs slowly through the various percolators and finally reaches the vacuum still, where it is distilled away and returned to the solvent tank, the perfume remaining in the retort. The process is repeated many times until the flowers are exhausted of their perfume. The product left behind contains insoluble waxes in addition to the perfume oil and at this stage is known as a "concrete." On treatment with alcohol and ultimate removal of the alcohol, the "absolute" is obtained. Jasmin flowers yield about 0.3% and roses about 0.24% of concrete. In some cases the petals are pressed to break up the cells and under these circumstances the yields are often higher.

In the enfleurage extraction method, the petals are placed on glass trays (chassis) upon which a layer of specially purified animal fat has been spread. The trays are stacked together so that

the petals are contained between two layers of fat and then are left for about 24 hr., during which time the volatile oils are absorbed by the fat layer. Petals are replaced by fresh ones every day until the fat is saturated with the flower oil. Extraction of the mass (the pomade) with alcohol separates the fat and yields the floral absolute.

Enfleurage extraction is particularly valuable in the case of certain flowers, *e.g.*, jasmin and tuberose, that continue to produce perfume after picking, for only by the gentle process of enfleurage is it possible to extract the maximum yield of oil from the petal. With most other flowers, the production of essential oils ceases on picking and therefore a more drastic extraction process, such as with hot fat, gives the maximum oil yield. Hot fat extraction has, however, been almost entirely superseded by solvent extraction. The enfleurage process does not remove all the oil from the petal and valuable oil is also lost in the traces of fat adhering to the exhausted petal. The exhausted petals are therefore normally solvent-extracted so that they yield the so-called absolutes of chassis.

As previously mentioned, oils are often distilled under very rough conditions. The collecting of the wood, leaves, etc., constitutes a great deal of work and time, and often one ton of vegetable matter will yield only a few pounds of oil. As the various small producers have to send their oils to central bulking depots, the oils that eventually arrive in the large collection centres (*e.g.*, a seaport) have passed through many hands. Thus much time, labour, and transport, to say nothing of supervision, is required to produce an essential oil.

The following chemicals are isolated from the essential oils, usually by distillation in a commercially pure state, and are employed in perfumery: geraniol and citronellal from citronella oil (Java, Formosa, and Chinese grades); citral from lemon-grass oil; eugenol from clove oil; linalool from bois de rose (rosewood) oil; and safrole from sassafras oil. In many cases the natural isolates are reprocessed to produce other important perfumery chemicals; *e.g.*, geraniol is converted to citronellol, citronellal to hydroxycitronellal, citral to ionone, eugenol to isoeugenol and vanillin, linalool to linalyl acetate, and safrole to isosafrole and heliotropin.

Products of Animal Origin.—Most of the animal products are used only in high-class handkerchief perfumes and in the form of alcoholic tinctures. They include musk from the musk deer, ambergris from the sperm whale, civet from the civet cat, and castoreum from the beaver.

Synthetic Chemicals.—There is a tendency to regard the synthetics in perfumery as "poor relations" of the natural products but this is completely unrealistic as an essential oil may cost much less than a synthetic. Further, the enormous number of man-made chemicals available to the perfumer make this group not only of great importance now but of even greater significance for the future. In addition, many of the important natural isolates have been synthesized and are available in large quantities; these products include citral, geraniol, linalool, and derivatives made from them. Important milestones in the development of synthetic perfumery chemicals include the synthesis of phenylethyl (phenethyl) alcohol by B. Radziszewski in 1876, musk xylol and musk ambrette by A. Baur in 1891, ionone by F. Tiemann and P. Kruger in 1893, hydroxycitronellal and undecalactone in 1905, and amyl cinnamic aldehyde in 1927 (synthesis published in 1927 although the chemical had been available previously).

The synthetic chemicals offer a wide selection of odour characteristics, ranging from those with typical floral effects to odours unknown in nature. Many thousands cover many types and strengths. Chemically, they include hydrocarbons, alcohols, esters, aldehydes, acetals, ketones, ethers, amino compounds, nitro bodies, lactones, phenols, and, in many cases, chemicals containing more than one of the foregoing groups.

Odour effects of a chemical depend upon many factors, *e.g.*, the presence of one or more active odour groups (osmophore), the position of the group, the presence and position of other groups in the molecule, the size of the molecule, and its vapour pressure. Literally hundreds of thousands of odorous chemicals are theoretically possible and many thousands have been prepared.

Certain of the synthetic chemicals possess odours that are distinctly floral in character; the chemicals and their odours include isoamyl salicylate (clover), amyl cinnamic aldehyde (jasmin), anisaldehyde (*p*-anisaldehyde; hawthorn), citronellol (rose), benzyl acetate (jasmin), cyclamen aldehyde (cyclamen), geraniol (rose), heliotropin (heliotrope), hydroxycitronellal (lily of the valley, lilac), ionone (violet), phenylethyl alcohol (phenethyl alcohol; rose), and terpineol (lilac).

Of special interest is a range of chemicals made with castor oil as the starting material. These include the above-mentioned amyl cinnamic aldehyde; undecalactone (peach odour), and *gamma*-nonyl lactone (coconut odour).

PREPARATION AND USE

The Architecture of a Perfume.—Is perfumery an art or a science? Without science little progress would have been made in perfumery. The scientist has given perfumery its raw materials, whether won directly from nature or produced by chemical synthesis; he adds continually to the vast store of raw materials and indicates the way in which they may be used in finished products. However, perfumery is an art and not a science: It is not enough to say science has provided an analysis of, say, rose oil; artistic creation is the key to the production of a successful rose perfume and no ordinary application of scientific data will achieve this end. Scientific blending of perfumery ingredients is not yet possible, but research indicates that it may become so.

It is not entirely fanciful to compare perfumery with music and painting. All three arts commence with a basic idea, the painter beginning with his background sketch, the musician with his theme or motif, and the perfumer with his skeleton or primary accord. Around and into these ideas are blended the harmonizing colours, sounds, and odours. The painter seeks to balance his light contrasts so that even the sharp edge of a table blends naturally into the scene. Balance in music is accomplished by the judicious harmonizing of instruments, or orchestration, and achieves accord by the use of different keys to avoid repetition.

The perfumer adds to his primary accord his harmonizing or blending odours. His equivalent of key variation and shading is his "layer blending," *i.e.*, his harmony of "top notes," "middle notes," and "back notes." The comparison may be pursued, for example, in the selection of one outstanding ingredient, whether sound, colour, or odour, and in the building up of the work around this basic subject. In music the concerto places emphasis on one instrument with orchestral accompaniment; in painting, a colour, say blue, is selected and laid shade on shade; and so in perfumery it is possible to select one odiferous body, for instance, amyl salicylate, patchouli, or even a rose or jasmin accord, and to build a perfumery concerto around it. Even a strong ingredient, difficult to use, may successfully be made the central odour of a perfume. Perfumery is more analogous to music than to any of the other arts, if only on account of the intangible nature of music and perfumery.

Such a description of perfumery implies that perfumers are artists, and it is true that a good perfumer must be aesthetically sensitive. It is, however, a hard fact that perfumers must practise their art against a commercial background, and sheer intuition is not a sufficient guarantee of success. After all, there is a low limit to the number of people who can be given the opportunity to spend their time in free experiment and the creation of new perfumes without at the same time contributing something to their application and indicating the nature of future requirements in the form of new ingredients. Ideally, the successful perfumer should have, as well as artistic sense, a sound background of organic, inorganic, and physical chemistry. If he is concerned with perfumes for cosmetics or soap, then he must possess an intimate knowledge of these subjects. Further, the perfumer has some thousands of raw materials to employ, he is concerned with the hazards his creation must eventually face, and, in addition, he often has to identify ingredients from a complex blend, and this calls for an intimate knowledge of large numbers of separate items. Finally, most perfumers must be able to give a critical assessment of the purity of the many raw materials with which they are concerned.

Manufacture.—The actual mixing together of the various ingredients of a perfume is not a complicated process. Once the formula has been established and the raw materials checked and accepted, then little remains but to stir them together into one homogeneous mixture. However, perfumery materials may be expensive and in many cases subject to deterioration if harshly treated. Further, a perfume will often consist of liquids, solids, and resinous products, which means that some special technique must be adopted to ensure a perfectly uniform mixture.

The size of batch production will to some extent decide the type of mixing vessel to be employed. Although glass may be used in the case of small production, stainless-steel vessels are normally employed. In most cases, the batch is mixed by high-speed propeller-type stirrers. The nonliquid portion of the formula is placed in the vessel and to this is added the relatively high-boiling ingredients. The contents of the vessel are thoroughly stirred until solution is effected. Under certain circumstances it is possible to introduce heat (up to 50° C) to speed up the rate of solution. The more volatile constituents are added when the mixture is cold and the whole is thoroughly stirred. The finished mixture is pumped from the vessel through a filter system to the storage vessels. It is essential that contact with copper and iron be avoided during all stages of production, as these metals may have adverse effects on the perfume constituents.

Use of the Finished Perfumes.—*Alcoholic Solutions.*—The word "perfume" is generally understood to mean the product sold in an attractive container for use on handkerchief, dress, or body. Such an item is an alcoholic solution of a complicated mixture of odorous ingredients. In a handkerchief perfume the odour ingredients may occur to an extent of 5% to 20%. In a toilet water (lavender water or eau de cologne) the amount may vary between 2% and 10%. The concentrated perfume is dissolved in alcohol, usually in glass-lined vessels, and allowed to mature for several months, after which the solution is filtered and bottled.

With the expensive type of perfume, use is made of tinctures (alcoholic solutions) of certain products. Thus tinctures of musk and ambergris are added at a late stage of manufacture. There are two reasons for this special treatment: in the first place, these materials are very expensive and, secondly, they require an individual alcoholic extraction and cannot be added to the original concentrated perfume.

Nonalcoholic Solutions.—Important as the alcoholic perfumes may be, in terms of tonnage they represent only a small portion of the odorous products sold in the world. Soap alone accounts for a large amount of the perfume used. In fact, many of the commercial products used in the 1960s contained perfume in some form. Cosmetics account for a large share of the more expensive perfumes used but huge amounts of inexpensive perfumes are used in the detergent industry. The rubber, leather, textile, plastic, and insecticide industries also make use of perfume.

The selection of a perfume for a specific product requires knowledge of the chemical and physical properties of the perfumery ingredients and of the product itself. There are two distinct aspects to be considered. In the first place, the odour of a chemical may be modified when placed in a new medium; *e.g.*, the odour of a perfume perceived in concentrated form or in alcoholic solution may be quite different when present in soap or detergent. Powders also exert a great effect on odorous materials; the effect is often selective, so that certain odours in a perfume may be accentuated in a base such as talc, while others may be considerably reduced. This can result in a complete unbalancing of the original odour effects. The second effect that may occur affects stability of both perfume and product. For instance, soaps may have an adverse effect on a perfume. Colour may develop or the perfume may deteriorate because of the alkaline nature of the soap. On the other hand, a perfume may itself exert an adverse effect on a product. The perfume may combine with ingredients in the product to produce unwanted colour or it may change the consistency of a product; *e.g.*, a perfume may reduce the stability of a cosmetic emulsion or change the original consistency in some way.

PERGA (Greek PERGE; modern MURTANA in the *il* of Antalya, Turkey), an ancient city of Pamphylia, situated about 8 mi. (13 km.) inland from the Mediterranean at the junction of a small stream (Sarisu) with the Cestrus (Aksu Cayi). It was a centre of native culture, as contrasted with Greek, which was predominant in Attaleia (Antalya), and a great seat of the worship of "Queen" Artemis, here represented as a human-headed cone, a purely Anatolian nature goddess.

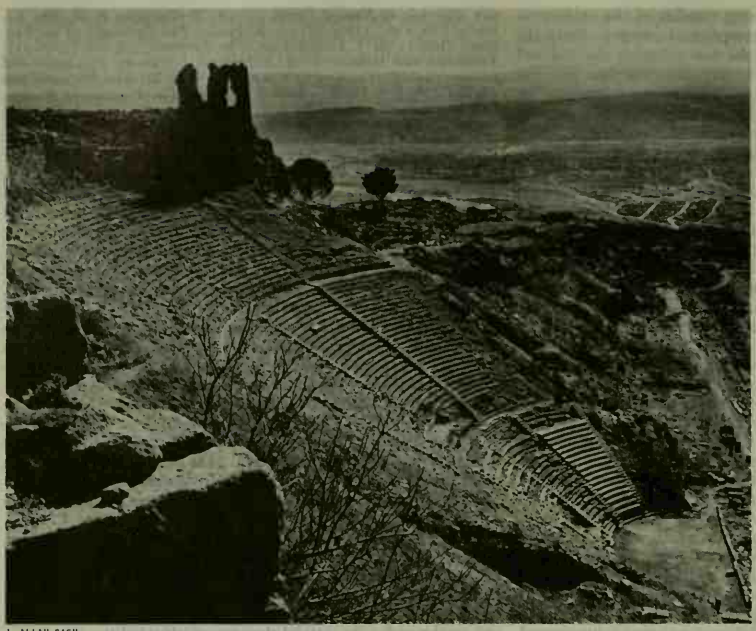
In Perga, Paul and Barnabas began their first mission in Asia Minor (Acts 13:13). A difficult mountain route into Phrygia began at Perga, and Alexander used it for his invasion of inner Asia Minor. Long the metropolis of Pamphylia Secunda, Perga was superseded in Byzantine times by its port, Attaleia, which became a metropolis in 1084. The extensive ruins all lie in the plain south of the acropolis. The walls, which are well preserved, are of late Roman or Byzantine reconstruction. The most notable monument is the theatre outside the walls on the southwest. Nearby is a fine stadium, while within the walls are ruins of two basilicas, baths, and the agora. (WM. C. B.)

PERGAMUM (PERGAMUS; modern BERGAMA in the *il* of Izmir, Turkey), an ancient Greek city in Mysia situated 16 mi. (26 km.) from the Aegean Sea on a lofty isolated hill (about 1,000 ft. [300 m.]) on the north side of the broad valley of the Caicus (modern Bakir) River. The peak of the hill served as a fortress and residence for the Attalid dynasty which ruled the city in the 3rd and 2nd centuries B.C. The residential part of the city was on the lower slopes of the hill, on ground now mostly occupied by the modern town. In the time of the Roman Empire the city was situated in the plain below.

Pergamum is known to have been in existence in the 5th century B.C., but practically nothing is known of its early history. As the capital of the Attalid dynasty it developed during the 3rd and 2nd centuries B.C. into a flourishing city. Though formally autonomous, it was completely under the control of the kings, who even regulated the functions of the minor magistrates.

Excavations, begun in 1878 under the auspices of the Berlin Museum, besides unearthing many artistic treasures, have enabled archaeologists to reconstruct the plan of the most important areas of the Hellenistic city. Cut into the western slope of the hill there stood a theatre. Above this lay the principal temple of the city, that of Athena Nicephorus, its courtyard set about with porticoes, with, on one side, the library (in fame second only to that of Alexandria). To the south lay the great altar of Zeus with its richly decorated frieze, a masterpiece of Hellenistic art and one of the wonders of the ancient world. A part of this altar and its surviving reliefs, restored and mounted, now stands in the Pergamon Museum in Berlin. On higher ground there was in Roman times a temple dedicated to the emperors Trajan and Hadrian (earlier probably the site of a temple of Zeus); the royal palace, the barracks, the storehouses, and the military arsenal stood close by. Below the altar of Zeus a street descended at a very steep incline to the central part of the city. Here lay what may be termed the civic buildings (as opposed to the royal structures of the upper city): a large market place, a gymnasium, and temples of Hera and Demeter. Roman remains include an amphitheatre, a theatre, and a racetrack. Outside the city to the southwest there was a temple of Asclepius, associated in the 2nd century A.D. with the activity of the famous physician Galen, who was a native of Pergamum.

Of the structures in the upper part of the Hellenistic city it would appear that the military buildings, the palace, and some of the religious monuments in their early form were erected in the 3rd century B.C. by the first rulers of the Attalid house. But a far-reaching program of rebuilding and new building was carried



J. ALLAH CASH

RUINS OF THE HELLENISTIC THEATRE AT PERGAMUM

through by the later kings Eumenes II and Attalus II, and it was chiefly their work that made the city famous for its architecture and its art (in spite of its library it never rivaled Alexandria in scholarship). Eumenes II built a very strong wall for the city and enlarged its area; he was also responsible for the development of the civic buildings referred to above. The work of the earlier king Attalus I, though overshadowed by the achievements of his successors, should not be overlooked. The kings after Attalus I are known to have collected many works of art from Greece to adorn the temples and courtyards of the city; these were additional to the numerous works of sculpture, painting, and decoration commissioned from resident artists.

Pergamum has a history of continuous occupation. Under the Byzantine Empire it was refortified. It passed into Muslim hands early in the 14th century. It is still an administrative and commercial centre of importance with a population in 1960 of 21,689. Its population in the time of the Roman Empire has been estimated at about 200,000.

PERGOLESI, GIOVANNI BATTISTA (1710–1736), Italian composer, whose intermezzo *La serva padrona* was one of the most celebrated stage works of the 18th century, was born at Jesi, near Ancona, on Jan. 4, 1710, the son of a surveyor. His family name was Draghi but, having moved to Jesi from Pergola, the family was called Pergolesi or Pergolese, meaning "of Pergola." Pergolesi first studied music locally. From 1726 he attended the Conservatorio dei Poveri at Naples, where his masters included D. Matteis, G. Greco, L. Leo, and F. Durante and where he earned a high reputation as a violinist. In 1731 his oratorios *La conversione di S. Guglielmo d'Aquitania* and *La morte di S. Giuseppe* and his opera *Salustia* were performed at Naples but with little success. In 1732, when he had become acquainted with the work of A. Scarlatti, he was appointed *maestro di cappella* to the prince of Stigliano at Naples and produced a Neapolitan *opera buffa*, *Lo frate 'nnammorato*, which was well received. In December of the same year his Mass, commissioned as a thanksgiving for delivery from an earthquake at Naples, was also performed with success. In August 1733 his most important stage work was first produced. This was not his *opera seria*, *Il prigionier superbo*, which received the cool reception usually reserved for his serious operas, but the gay little intermezzo *La serva padrona*, on a libretto by G. A. Federico, inserted between the acts. In February 1734 Pergolesi was appointed deputy *maestro di cappella* of Naples and in May went to Rome to direct the performance of his Mass in F. In October 1734 he produced another *opera seria* at Naples, *Adriano in Siria*, with the intermezzo *Livietta e Tracollo*. On his return to Rome his best *opera seria*, *L'Olimpiade*, met with no more success than his Neapolitan ventures. His comic opera *Flaminio* was well received in Naples in 1735; but his health was now failing, and in February 1736 he left Naples for the Capuchin monastery at Pozzuoli, near Naples. There he managed to finish his last work, the celebrated *Stabat Mater*. He died in extreme poverty at the age of 26 and was buried at the cathedral at Pozzuoli on March 17, 1736.

When Pergolesi died his fame had scarcely penetrated beyond Rome and Naples, but later in the century his reputation grew enormously. After the posthumous success of *La serva padrona* and particularly after its performance in 1752 in Paris, where it led to the *guerre des boufons* (*see* OPERA: *18th-Century Developments*), forgers became busy producing spurious Pergolesiana, and a number of works bearing the composer's name are either known to be by other composers or are of doubtful authenticity. These include some of the works ascribed to Pergolesi by Igor Stravinsky in the arrangements he made for his ballet *Pulcinella*, produced by Sergei Diaghilev in 1920. Pergolesi's serious style is best illustrated in his *Stabat Mater*, his ability to wield large choral and instrumental forces, in his Masses, and his gift of comic characterization in *La serva padrona*.

His works, *Opera omnia*, were edited by F. Caffarelli in 27 volumes (1939–42). They include some works of doubtful authenticity, such as the six concertinos for strings published at The Hague about 1730 by C. B. Ricciotti and the trio sonatas which in some early manuscripts are ascribed to D. Gallo.

PERI, JACOPO (1561–1633), Florentine singer and the first composer of opera. Born in Rome on Aug. 20, 1561, of noble stock, he studied with C. Malvezzi in Florence and entered the service of the Medici about 1590. He became a member of Count Bardi's *Camerata*, the learned coterie that attempted to reconstruct the authentic presentation of ancient Greek drama; they held that the plays were sung throughout, and their desire to find a form of

music completely subservient to the words and the dramatic action led them to abandon traditional polyphony and to experiment with recitative—a lightly accompanied, naturalistic speech-song for voice and continuo alone. Ottavio Rinuccini's *Dafne*, a pastoral play modeled on T. Tasso and G. B. Guarini, was set to music in this style by Peri (with some contributions from Count Corsi) and performed with great success in 1597. The music of *Dafne*, the first opera, is almost entirely lost, but Peri's next work (a setting of Rinuccini's *Euridice*) was printed and survives; it was commissioned for the wedding of Maria de' Medici and Henry IV of France on Oct. 6, 1600. *Tetide* (1608) and *Adone* (1620), written for Mantua, apparently remained unperformed and are now lost. Marco da Gagliano's *Flora* (Florence, 1628), for which Peri wrote and sang the part of Clori, survives. From 1609 to 1625, Peri composed or collaborated on ten ballets, *feste*, masquerades, and interludes for the Florentine court; none of these found a printer and most have disappeared. Further short pieces in manuscript and printed collections, together with *Euridice* and the fine continuo madrigals of *Le varie musiche* (1609), show Peri as a sensitive composer, remarkable as much for his control as for his daring. He died in Florence on Aug. 12, 1633.

PERIANDER (ruled *c.* 627–586 B.C.), the second tyrant of Corinth (*q.v.*). In contrast with his father, Cypselus, the founder of the dynasty, he is generally represented by Greek writers as a cruel despot, the tyrant par excellence. Much of this tradition probably derives from the Corinthian nobility, with whom he appears to have dealt harshly. The firmness and activity of his government are beyond dispute. It is said that under him the commercial prosperity of Corinth was so great that he could rely for revenue on tolls on goods entering Corinthian ports. To promote and protect Corinthian trade he established colonies at Potidaea in Chalcidice and at Apollonia in Illyria; he is said to have built the carriageway (*dialkos*) across the Isthmus of Corinth and to have planned a canal through it. In Greece proper he conquered Epidaurus and annexed Corcyra. He cultivated friendly relations with Thrasybulus, tyrant of Miletus, and maintained a connection with the kings of Lydia and of Egypt; his nephew and successor, Psammetichus, was so called after the Egyptian pharaoh Psamtik. Periander arbitrated in the struggle in northwestern Asia Minor between Athens and Mytilene, and awarded Sigeum to Athens.

Periander was also a patron of literature, for it was by his invitation that the poet Arion came to Corinth from Lesbos. He was reckoned one of the Seven Wise Men of Greece and was the reputed author of a collection of maxims in 2,000 verses.

PERICARDIUM, DISEASES OF. The serous sac (pericardium) containing the heart may become the seat of inflammation (pericarditis) just as the cardiac valves and heart muscle may during the course of such acute diseases as rheumatic fever. (For anatomy, *see* COELOM AND SEROUS MEMBRANES.) The normal shiny appearance is lost; the membrane becomes congested; and inflammatory serum exudes into the cavity. In this stage the visceral and parietal layers grate upon one another with each heartbeat and give rise to a "friction rub" over the front of the chest which can be heard with the stethoscope and may be perceptible to the hand. As more inflammatory exudate collects, the surfaces are separated and friction disappears. Thereafter the course of the disease varies as the inflammation advances or recedes. The accumulation may become so extensive that it seriously impedes cardiac action; and if the pericarditis accompanies or follows pneumonia the fluid may become purulent. In either event exit must be given to the fluid surgically.

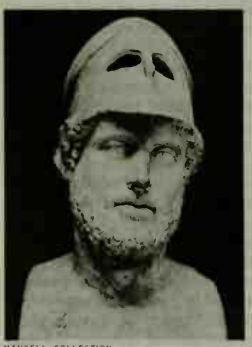
If the disease recedes the roughened pericardial surfaces again come into contact through absorption of the exuded fluid and friction reappears. Fibrous adhesions form between the pericardial layers over a greater or smaller area; sometimes they become universally adherent and the cavity is obliterated. Occasionally when the covering of the heart and the lining of its sac become firmly adherent one to another, the mechanical function of the heart is disturbed and congestive heart failure results. Calcium may be deposited in the pericardium, making the diagnosis much easier by its appearance in X-rays of the chest. For this condition there are highly successful surgical procedures.

Exudation of fluid into the pericardial cavity, apart from inflammation, occurs in certain diseases of the kidney; however, in these cases, which are often unaccompanied by symptoms, it is a serious omen. In rupture of the heart or in certain varieties of aneurysm the pericardial sac is suddenly filled with blood. Distress is extreme, and death from mechanical interference with the action of the heart occurs after a few seconds.

Another condition that occasionally results in accumulation of fluid in the pericardial sac is myxedema (hypothyroidism). This condition can be completely alleviated by the administration of thyroid extract. Tumours of the pericardium are very rare and are nearly always benign. They may cause mechanical difficulty in the heart's activity. *See* also HEART, DISEASES AND DEFECTS OF; HEART AND LUNG, SURGERY OF. (W. S. L.-B.; E. B. BY.)

PERICLES (*c.* 495–429 B.C.), Athenian statesman, largely responsible for the full development in the later 5th century of both the Athenian democracy and the Athenian Empire.

Background.—Pericles was the son of distinguished parents. His father, Xanthippus, a member of the leading house of a powerful Attic clan, probably the Buzygae, was an outstanding figure in the generation of the Greco-Persian Wars. His sympathies were then with the democratic group in the state, and he led the prosecution in the trial of Miltiades. In 485/484 he was ostracized by the people, who gave their favour to Themistocles, but he was recalled on the eve of the Persian invasion, commanded the Athenian squadron at Mycale, and conducted the siege of Sestos. Nevertheless he was rapidly displaced by Miltiades' son, Cimon (*q.v.*); for the conservative group, led by the Areopagus Council, became dominant in the state after 478. The mother of Pericles, Agariste, was a niece of Cleisthenes, leader of the very wealthy Alcmaeonid clan, who had reformed the constitution in the democratic interest in 508–507 and had shown an unrelenting hostility toward Sparta. Pericles thus had an immediate entry into the ranks of the aristocrats and of the democratic group, "the people's faction," as it was called, and to his inherited assets of wealth and reputation he added an obviously able mind, a convincing integrity of character, and fine powers of oratory. By 465 when he was 30 years old, he shared the leadership of the democratic group with an older statesman, Ephialtes.



MANSELL COLLECTION

BUST OF PERICLES, FOUND AT TIVOLI, A ROMAN COPY FROM A MID-5TH-CENTURY B.C. MARBLE HERM, IN THE BRITISH MUSEUM

Pericles grew up in a period of confidence. The Greek states had defeated the mighty power of Persia, and Athens had become the acknowledged leader of a great alliance. The older generation, whose views are represented at their finest by Aeschylus (d. 456), had a deep faith in the orthodox religion of the Greeks; but the younger generation contained men of adventurous mind who preferred a more intellectual philosophy. Pericles combined a serene confidence with an original mind. His friends included Anaxagoras of Clazomenae, a rationalist who attributed the movements of the universe to physical processes activated by "mind"; Zeno of Elea, whose speculations on time, space, and movement gave rise later to the atomic theory of Leucippus; Damon of Athens, musician and philosopher, who inspired some of the tenets of the democratic

group; and Phidias of Athens, who sculpted the finest statues of Zeus, the god of the Greeks, and of Athena, the patroness of Athens. Pericles was, like them, progressive in his attitude to philosophy, music, and art, and he was a political theorist as well as a practical politician.

The Development of Democracy.—In 465 Athens stood at a crossroads. The policy of the Areopagus Council—hostility to Persia, friendship with Sparta, and cooperation with the allies in the Delian League—had culminated in Cimon's decisive victory over Persia at the Eurymedon River, and it was possible for Athens to continue the same policy. An alternative line of reasoning was that the defeat of Persia made it no longer necessary to be friendly with Sparta and to cooperate with the allies; a more strictly Athenian policy might now be pursued, but not so long as the Areopagus Council and Cimon were at the helm of the state. In 465 Athens inclined toward the second policy in attacking one of the strongest allies, Thasos, which had justifiably refused to give Athens a share in its possessions. At this time Ephialtes and Pericles opened a series of prosecutions against leading members of the Areopagus Council, who were tried in the people's courts. Some of these were successful, but a charge of corruption, laid against Cimon by Pericles, failed, probably in summer 462. A trial of strength occurred when Sparta appealed for help against the Messenians and the Spartan serfs, the helots. Ephialtes, describing Sparta as Athens' rival in the struggle for power, advocated refusal, but Cimon recalled the days of Spartan and Athenian cooperation against Persia and persuaded the assembly to send help. The issue was decided at home when Cimon and the hoplites of the army were overseas on service. Then Ephialtes and Pericles obtained a majority in the assembly to rescind many powers hitherto held by the Areopagus Council and to transfer them to the democratic Council of Five Hundred (the boule; *q.v.*) and to the people's courts. When Cimon returned, the people confirmed their choice of the democratic leaders by ostracizing him in the spring of 461. A month or two later Ephialtes was assassinated, and Pericles found himself the surviving leader of the democratic group.

Pericles was a firm believer in the sovereignty of the people, which was directly expressed in the majority vote of the citizens in the assembly and of a section of them in the people's courts. On his proposal the assembly removed further powers from the Areopagus Council, and the people's will was now untrammeled except by the rules of procedure (which required, for example, a preliminary recommendation by the boule) and by respect for established law and precedent. During the next ten years most offices of state were made open to any citizen, whatever his financial position might be; state judges were instituted to supervise local courts and curtail local influence; and on Pericles' own proposal Athenian citizenship was granted only to men of Athenian parentage on both sides. Thus the privileged circle of citizenship was closed, and within it equality of political opportunity under the democracy was safeguarded. Thus in 462–454 the foundations of the Periclean type of democracy were firmly laid, and there is no doubt Pericles himself played the leading part in the development.

The Policy of Expansion.—In the field of foreign affairs Pericles had less experience in 461. As a general he was far surpassed first by Cimon and then by Tolmides, Myronides, and others, but as an orator in the assembly he was able to influence the foreign policy of the state. In the hour of Sparta's weakness the Athenians allied themselves with Sparta's enemies Argos and Thessaly, and then with Megara against Sparta's loyal ally Corinth; and they delivered a strong offensive against Epidaurus, Corinth, and Aegina in 458. Next year the Spartan army, weakened though it was, joined forces with the Boeotians and marched toward Attica. Pericles distinguished himself in the ensuing battle at Tanagra, the only occasion in his lifetime when the Athenian army faced a Spartan army in battle. The verdict was slightly in favour of Sparta; the Spartan army marched home through the territory of Megara, and the point was established that Athens had little or no hope of defeating Sparta on land. Boeotia, however, was exposed to attack by the Athenians, who overran the cities and set up a number of "democratic" governments. In the same year, 457, Pericles achieved his desire to conquer Aegina, "the eyesore of the Piraeus," as he called it, and he completed the task entrusted to him by the assembly, the building of the Long Walls from Athens to the Piraeus which made the city almost impregnable and ensured access to the sea. The Athenian navy raided the coasts of the Peloponnese, occupied Naupactus as a base in the Corinthian Gulf, and under Pericles' command in 455 won over most of Acarnania. The spectacular success of Athenian arms, except in the all-important trial of military strength with Sparta, seemed to justify the adventurous foreign policy of the democracy, even if it involved some rough handling of the allies in the Delian League. (*See* also DELIAN LEAGUE.)

Simultaneously, however, Athens engaged in a major war in Egypt against Persia. It is not known whether Pericles favoured this course, but he certainly learned from it to avoid a war on two fronts. At first all went well; an allied fleet, to which Athens contributed only a small squadron, won a victory on the Nile and the Egyptians expelled the Persians. But the Persians returned to the attack in strength and captured the entire expeditionary force in 454. This disaster shook Athens' position as a sea power and as leader of the allies in the Delian League. The people turned to Pericles in this crisis. He took command of the western fleet and brought it to the Piraeus; he was given charge of the "allied treasury," which the Athenians transferred from Delos, thus depriving the allies and making themselves masters of great financial reserves; he desisted from operations against the Peloponnese and then obtained a truce through the good offices of Cimon, who was recalled, on the proposal, probably, of Pericles. The truce lasted to 446. Meanwhile Pericles concentrated on recovering a number of allied states which had seceded from the Delian League and on preparing for an offensive against Persia; in 450 Cimon led a fleet of 200 ships to victory in Cyprus and died shortly afterward. Negotiations were opened with Persia, and peace was concluded in 449/448 with defined spheres of interest.

The Athenian Empire.—Although Pericles left negotiations with Sparta and war with Persia to Cimon, he outmaneuvered him at home and carried through two radical policies. He confirmed the people's loyalty to the democracy by enlarging the number and the powers of the people's courts and by introducing a system of state pay, which benefited the poorer citizens especially and enabled them to fulfil political and judicial functions. Second, he converted the Delian League from an alliance to an empire by reducing to dependent status those states which had revolted and by planting outposts of Athenian citizens, known as cleruchies, at strategic points on "allied" territory. His methods involved political, military, and judicial intervention, but he was probably correct in seeing that otherwise the Delian League would dissolve and leave Greece weaker in facing Persia. His main concern, as always, was the aggrandizement of Athens, and he tried to isolate Sparta by a diplomatic offensive, probably in 448. He invited all Greek states to attend a panhellenic conference at Athens, where it was planned to celebrate the end of the Greek war with Persia, terminate all internal wars in Greece, and proclaim the freedom of the seas for all Greek ships. But the members of the Spartan alliance refused the invitation, and no conference was held.

Even with Persia at peace and the empire under control, Pericles just saved Athens from disaster in 446–445. The oligarchs whom Athens had exiled from Boeotia, Locris, and Euboea combined to defeat an Athenian army and liberated the whole of Boeotia from Athens. Then Euboea revolted, and while Pericles led an army thither the Megarians rose and killed the Athenian garrison. Pericles hurried back to find a combined army of Peloponnesians, Megarians, and Boeotians invading Attica under the command of a Spartan king. The army suddenly withdrew. Pericles, it was believed, had bribed the Spartan king. Negotiations were opened for a settlement. During them Pericles reduced Euboea to obedience. In winter 446–445 the Thirty Years' Treaty was concluded: it was a pact of nonaggression between two blocs of power —Athens and its empire and Sparta and its allies—and any dispute was to be settled by arbitration. Of disputed territories the Athenians were allowed to keep Naupactus, Aegina, and Euboea. The extrication of Athens from its dilemma in 454, the formation of the Athenian empire, the strengthening of the democracy, and the

securing of peace with Persia and Sparta were primarily due to Pericles, who had shown the highest gifts of diplomacy, foresight, and forcefulness.

The "Periclean Age."—Respite from war enabled Pericles to picket the empire more securely. Cleruchies were planted at Histiaea and Chalcis in Euboea, at Brea on the Thracian coast, and in the Chersonese. Athens still demanded tribute. With it Pericles maintained a standing fleet of 60 triremes to police the seas and launched a great building program to which the Parthenon and the Propylaea on the acropolis, the temples of Athena and Hephaestus and Ares in the agora, and those of Poseidon at Sunium and Nemesis at Rhamnus still bear witness. The policy of exploiting the so-called allies was challenged by Thucydides, son of Melesias, a relative of Cimon, who claimed that the Athenians had no right to use the allies' money in decking Athens out "like a harlot with jewels and statues and temples." In 443 the people chose between imperialism and cooperation: Thucydides was ostracized. Opposition to Pericles was thereafter expressed not in the assembly but in pamphlets such as the *Constitution of Athens,* falsely attributed to Xenophon and often referred to as "The Old Oligarch," composed *c.* 431. Opposition in the empire came to a head in winter 441/440, when Samos, one of the few allies still possessing a fleet, refused to accept arbitration by Athens in a quarrel with Miletus.

Pericles attacked at once and successfully. He imposed a heavy fine on Samos, removed a hundred hostages, set up a "democratic" government, and left Athenian commissioners and a garrison to support it. But the Samians, in collusion with the nearest Persian satrap, rebelled once more, and Byzantium rose in sympathy. Pericles had to deploy 200 ships and conduct a siege for nine months before the Samians capitulated on condition that they lost their fleet and walls, paid the cost of the war, and gave hostages to Athens. An example had been made of the strongest surviving "ally," and the peace treaties with Sparta and Persia had held firm during this dangerous operation.

Pericles also enlarged the area of Athens' influence between 445 and 435. Good relations with Egypt brought Athens gifts of grain; alliances were renewed with Rhegium in Italy and Leontini in Sicily; Thurii was founded in south Italy as a colony under Athenian leadership for volunteers from any Greek state; operations in the Ambraciote Gulf brought an alliance with Acarnania; a colony for Athens and its allies was founded at Amphipolis on the Strymon River in Thrace; and a strong fleet, commanded by Pericles, toured the Black Sea, planted colonies, and brought new accessions to the empire.

The constant activity of Athens was viewed with alarm by Sparta and its allies. At first Pericles was careful to observe the principles of the balance of power under the Thirty Years' Treaty by leaving the western seas to Corinth and keeping the Aegean free to Greek traders. But in 435 a quarrel started between Corinth and Corcyra, which endangered Corinth's sea power in the west. In 433 both states sent embassies to Athens. Advocates of peace advised the Athenians to keep clear of the quarrel, but Pericles persuaded the assembly to make a defensive alliance with Corcyra, and Athenian ships fought against Corinthian ships that autumn. In 432 Pericles proposed and carried a decree excluding Megara from all Athenian ports; and a colony of Corinth in the Aegean, Potidaea, ordered to dismantle its defenses, refused, hoping for help from Corinth and Macedonia. The nature and timing of these actions show Pericles determined to apply severe pressure on Sparta's allies, even at the risk of a general war. In 432 the Spartans took up the challenge: "If Athens," they said, "would retract, then peace would continue"; the alternative was war. Pericles advised the people not to yield, and hostilities began in 431.

The zenith of Pericles' career was in 445–431, the so-called Periclean Age. The balance of power with Persia and Sparta which gave Athens an assured peace and a growing prosperity was primarily due to his intelligent statesmanship and lasted as long as he wished it to last. Some of the wealth which accrued to Athens was expended at his direction on the magnificent temples and festivals, the fortifications and the fleet, and the policing of the seas. The democracy was developed and led by him. The large and enlightened middle class provided unusual stability under a constitution which entrusted all powers of direct government to the people, and Pericles' ideal of a liberal democracy with no social or financial barriers (as expressed by Thucydides the historian) came as near to actuality as was possible in an exclusive citizen body resting on a basis of slavery. Pericles was the pivot on which the constitution turned. He was elected each year by the whole people as their chosen general for 14 years in succession. His integrity, ability, and experience enabled him to dominate the assembly and impose his will alike in domestic and foreign policy. He inspired the citizens with his unqualified loyalty to Athens and with his ambitions for its future.

Peloponnesian War and Death.—Pericles was confident of defeating Sparta (*see* PELOPONNESIAN WAR) by a strategy of defense by land and offense by sea, causing a war of attrition in which a naval offensive would impoverish Megara, Corinth, Sicyon, and others, split the Spartan alliance, and force Sparta to a humiliating peace, whereas Athens had capital reserves, unassailable sea power, and an empire for supplies. For two years his strategy succeeded. He was chosen in 430 to deliver the funeral speech for the dead of the first year of the war and to command a raiding force of 150 triremes. Then plague struck Athens. One-third of the best troops died, including two sons of Pericles. He was deposed and fined by the demoralized citizens. They elected him general again in 429, but he died before the end of the year. Whereas his successors failed, Thucydides the historian believed Pericles would have led Athens to victory with that certainty of judgment and power of command which he had always shown. Posterity has been more impressed by the advanced democracy and the intellectual culture which he had created.

Pericles had a high forehead (the Attic comedians called him "squill-headed") and a composed, dignified expression which can be seen in a copy of a bronze head by Cresilas at the British Museum (no. 549). In private life Pericles associated himself with the progressive intellectuals, both thinkers and artists, some of whom suffered in the people's courts. He was a close friend of Sophocles, whose plays had something of Pericles' own serenity, confidence, and refinement. He formed a lifelong attachment to a courtesan, Aspasia (*q.v.*), who rivaled him in intellectual and cultural interests. His son by her, also called Pericles, was one of the generals at the Battle of Arginusae who were condemned to death in a mass trial by the democracy in 406.

PERIDOTITE is a dark, heavy, igneous rock containing at least 10% olivine; other iron- and magnesia-rich minerals, generally pyroxenes; and not more than 10% feldspar. Most peridotites are coarse-grained and granitoid, although some are coarsely porphyritic. Peridotite occurs in four main geologic environments: (1) interlayered with iron-, lime-, and magnesia-rich rocks in the lower parts of tabular-layered igneous complexes or masses; (2) as irregular masses, rich in olivine $(Mg,Fe)_2SiO_4$, with or without related gabbro, in alpine-type mountain belts; (3) in volcanic pipes (the variety known as kimberlite); and (4) as dikes and irregular masses with rocks exceptionally rich in potash and soda. The layered complexes are believed to have been formed in place by selective crystallization and crystal settling from a previously intruded fluid or magma; the remaining types seem to have ranged from fluid magmas to semisolid crystal mushes at the time of emplacement. Nearly all peridotite is more or less altered to serpentine (*q.v.*) and cut by many irregular shear surfaces.

Peridotite is the ultimate source of all chromium ore and naturally occurring diamonds, and of nearly all chrysotile asbestos. It is one of the main host rocks of talc deposits and platinum

metals and formerly was a major source of magnesite. Some varieties of serpentine (verd antique) are used as building and ornamental stone, and fresh dunite (pure olivine rock) is used in parts of glass furnaces. In warm humid climates peridotite and serpentine have weathered to soils and related deposits (*see* LATERITE) which, though now worked on a relatively small scale, are enormous potential sources of iron, nickel, cobalt, and chromium. (T. P. T.)

PÉRIER, CASIMIR PIERRE (1777–1832), French banker and statesman who exercised a decisive influence on the political orientation of the July Monarchy, was born at Grenoble on Oct. 21, 1777. He was the son of the manufacturer and financier Claude Périer (1742–1801), who dealt in national property (real estate) and became one of the first directors of the Banque de France. After service with the staff of the French Army in Italy (1798–1801), Casimir Périer returned to France and, together with his brother Antoine Scipion, founded a new bank. By 1814 Périer was one of the most important bankers in Paris; and he then had some part in the financial negotiations between the fallen emperor Napoleon, the French provisional government, the victorious Allies, and the Bourbon dynasty. Under the Restoration, when the duc de Richelieu's government in 1817 relied chiefly on foreign banks, especially the Amsterdam House of Hope and the London House of Baring, for the floating of a loan, Périer proposed on the contrary that French banks should play the preponderant role in it. Elected to the Chamber of Deputies to represent first Paris (from 1817) and then Troyes (from 1827), he sat with the moderate opposition of the left.

On the revolution of July 1830, which made Louis Philippe king of the French, Périer was elected president of the Chamber. He promptly made himself the spokesman of the "party of resistance," that is, of the right, in opposition to his rival Jacques Laffitte (*q.v.*). On March 13, 1831, he succeeded Laffitte as president of the Council of Ministers (premier) and minister of the interior. He thereupon set himself to restore order: the National Guard was brought into action against the demonstrations of the opposition in Paris; and later the Army put down the silkworkers' insurrection in Lyons (November–December 1831).

Périer pursued his own line in foreign affairs. Determined to resist the spread of revolution, he declined to intervene on behalf of the Polish insurgents against Russia. But he dispatched a naval squadron to Lisbon to force the absolutist government of Dom Miguel to compensate French merchants for damage (July 1831); he sent an army to defend the new kingdom of the Belgians against the Dutch (August 1831); and he ordered the occupation of the Adriatic port of Ancona by a French brigade, so as to check Austrian predominance in the Papal States (February 1832). Despite this active policy, he had to face continual attacks from the left and from the Legitimists; and his authoritarian manner sometimes alienated Louis Philippe also. Périer died in Paris on May 16, 1832, during the cholera epidemic. (JE. V.)

PERIGEE, in astronomy, that point in the orbit of a satellite, natural or artificial, which is nearest to the earth (Gr. *peri,* "near," *ge,* "the earth"). The perigee of the sun's apparent orbit and the earth's perihelion (*q.v.*) are so related that they differ 180° in longitude, the first being on the line from the earth toward the sun, and the second from the sun toward the earth.

PÉRIGNON, DOMINIQUE CATHERINE, MARQUIS DE (1754–1818), French army officer who made his name during the French Revolutionary Wars and became one of Napoleon I's marshals, was born at Grenade, near Toulouse, on May 31, 1754, of a family of lawyers. Having retired from the royal army, he was elected to the Legislative Assembly in 1791 but soon resumed active service. In 1793, when the Spaniards invaded Roussillon, he did well in the confused fighting there; and in 1794 he led the centre of Gen. J. F. Dugommier's army of the Eastern Pyrenees, which expelled the invaders and advanced into Catalonia. When Dugommier was killed (Nov. 18), Pérignon assumed command and took Figueras ten days later and Rosas in Feb. 1795. Under the Peace of Basel (July 1795), he went as the French Republic's ambassador to Madrid (1796–98). In 1799 he commanded a wing in Italy and was wounded and taken prisoner by the Russians at Novi (Aug. 15). Released, he was made a senator of France in 1801.

Pérignon was well treated by Napoleon, who made him a marshal (1804), governor of Parma (1806), and comte (1808). From 1808 he served in Naples. Adhering to the Bourbons on Napoleon's downfall, he was named a peer of France (1814) and appointed commanding officer first at Toulouse (1815), then in Paris (1816). Created marquis in 1817, he died in Paris on Dec. 25, 1818.

PÉRIGORD, an ancient *pays* (district) of southern France, corresponding to the bulk of the modern *département* of Dordogne (*q.v.*), with part of Lot-et-Garonne. It was bounded north by Angoumois, northeast by Limousin, east by Quercy, south and southwest by Agenais, and west by Bazadais, Bordelais, and Saintonge. The name was derived from that of the Gallic tribe of the Petrocorii or Petragorici, whose capital became Périgueux (*q.v.*). Sarlat, Bergerac, and Nontron were also important places. Counts of Périgord are recorded early in the 6th century A.D. and in 778. After a period in which the countship was attached first to that of Angoulême (*c.* 866–*c.* 963), and then to that of La Marche, it became a separate entity again *c.* 1006. Apart from quarrels with the bishops of Périgueux, the counts played their part in the troubled affairs of Aquitaine; and with the formal reduction of Aquitaine to Guienne in 1259 Périgord became an area of disputed suzerainty between the French and the English crowns (*see* GUIENNE; HUNDRED YEARS' WAR). Confiscated from the feudal dynasty of counts (1399), Périgord was granted to Louis de France, duc d'Orléans, but Charles d'Orléans sold it to the House of Blois-Penthièvre in 1438. Transferred to the House of Albret by marriage (1470), it was subsequently inherited by the crown of Navarre, and so was finally united with the French crown by Henry IV (1589). Under the *ancien régime* it was included in the province of Guienne and the *intendance* or *généralité* of Bordeaux.

BIBLIOGRAPHY.—Société Historique et Archéologique du Périgord, *Bulletin* (1874–1947); J. L. Dessalles, *Histoire du Périgord,* 3 vol. (1886); A. Escande, *Histoire du Périgord,* 2 vol. (1934).

PÉRIGUEUX, a town of southwest-central France, *préfecture* of the *département* of Dordogne (former capital of the medieval province of Périgord Blanc), and an episcopal see, lies on the right bank of the Isle River, 120 km. (75 mi.) ENE of Bordeaux by road. Pop. (1962) 36,585.

Its two nuclei are the Cité and Puy-Saint-Front districts. The former occupies the site of the Roman town of Vesunna to the southwest; the latter, the medieval town to the east, surrounds the cathedral of Saint-Front. The modern town spreads to the west and northwest of Puy-Saint-Front. The cathedral of Saint-Front is a domed church of the Aquitanian school, built *c.* 1125–50. It has the shape of a Greek cross, with five lofty domes; and the in-

BY COURTESY OF THE FRENCH GOVERNMENT TOURIST OFFICE, CHICAGO

THE CATHEDRAL OF SAINT-FRONT IN PÉRIGUEUX, BUILT ABOUT 1125–50

terior is very bare. Its somewhat Byzantine appearance is due to wholesale restoration in the 19th century by Paul Abadie (the architect of Sacré Coeur in Paris). There is a Romanesque bell tower and 13th–14th-century cloisters are on the south side. At the northern edge of Puy-Saint-Front is the Musée du Périgord, with prehistoric and archaeological exhibitions as well as later secular and ecclesiastical art. In the Cité is the 12th-century church of Saint-Étienne, which was the cathedral until 1669 despite severe damage in 1577 during the Wars of Religion.

Northwest of this is a Roman arena of the 3rd century A.D.; and southwest stands the Château Barrière (12th–15th century) built on the boundary wall of the Roman *civitas*. Farther south, across the railway, is the so-called Tour de Vésone, believed to have been part of a Gallo-Roman temple to the goddess Vesunna.

Originally, Périgueux was the settlement of a Gaulish tribe, the Petrocorii, who called it Vesunna after a local spring which became their tutelary deity. When the barbarians came it shrank to a small encampment, the *civitas Petrocoriorum*—hence the modern forms, Cité (the part of the town where the *civitas* was situated) and Périgueux. A medieval town, Puy-Saint-Front (after St. Fronto or Frontonius, the apostle of Périgord in the 2nd century and Périgueux's first bishop) grew up between the 5th and 14th centuries around an abbey, burned down in 1120 and later replaced by the cathedral of Saint-Front. Périgueux struggled against the English throughout the Hundred Years' War, although they held it from 1361 to 1369. It suffered severely under Protestant occupation (1575–81) during the Wars of Religion. Amnestied by Louis XIV in 1654 for its part in the Fronde, it settled thereafter into an era of peace; but it had still to defend its privileges from the encroachment of centralized bureaucracy.

Under the Revolution, Périgueux continued as capital of a *département* covering exactly the same area as Périgord. From the July Monarchy (1830) onward many improvements were made and the town received new impetus under the Second Empire and the Third Republic. It is now one of the most attractive towns in southwestern France.

Périgueux is a road and rail junction, especially northeast for Limoges and southwest for Bordeaux. It is about 300 mi. (482 km.) from Paris by road and rail. There is an airport 5½ mi. (8.8 km.) E at Bassillac. Motor coach tours are organized for visitors wishing to see the surrounding countryside.

Internationally known for its pâté de foie gras, truffles, and wines, Périgueux is also an important hog market. Vegetable preserving is also carried on; and industries include the manufacture of hardware, cutlery, chemicals, textiles, and leather goods.

PERIM (Arabic MAYUN), an island and British possession in the Bab al Mandeb Strait about 100 mi. (160 km.) W of Aden. Pop. (1960 est.) 500. Area 5 sq.mi. (13 sq.km.). Perim is volcanic in origin, bare and strewn with boulders, and rather flat, with its highest point (214 ft. [65 m.]) in the south. It has a good small harbour on the southwest, with an entrance 860 yd. (786 m.) wide, and a small airfield. Perim, called Diodorus in the *Periplus*, was explored by Affonso de Albuquerque, who set up a cross there in 1513 and called it Vera Cruz. It was occupied by the French in 1738, and by the British in 1799. It was abandoned shortly after as waterless but reoccupied in 1857, just prior to the cutting of the Suez Canal, as a coaling and cable station. Both activities ceased in 1936. Included in Aden Colony in 1937, it was separated in 1963 by the Perim Order in Council. The High Commissioner of Aden is the legislative authority for Perim, while administration is in the hands of a commissioner for Kamaran and Perim. (W. H. Is.)

PERINTHUS: *see* HERACLEA.

PERIODICAL. This term, which was once applied to all publications appearing at regular intervals, is now used by librarians and others to designate all such serials except newspapers (*q.v.*).

Early Periodicals.—The forebears of the literary periodical in the 17th century were the book notices inserted by publishers in the early newsbooks. By 1646 such notices, accompanied by short critical comments, were appearing with some regularity; about 1650 they began to be grouped together and to form a regular feature of the newsbook or paper. Of far greater importance than the book notice was the digest or abstract journal, of which the pioneer was the *Journal des sçavans* (later *Journal des savants*), first issued in Paris on Jan. 5, 1665, by Denys de Sallo and continued in a series unbroken except for a short period of suppression from 1797 to 1816. Though original material began to appear in it after the issue of the first few numbers, its primary aim was to give summaries of all important books published in Europe, together with obituaries and bibliographies of prominent writers and reports on important philosophical, literary and scientific matters. The *Journal des sçavans* was closely followed by the *Philosophical Transactions (Acta philosophica)* of the Royal society of London (March 1665), the first abstract journal in English, designed to record "the present undertakings, studies and labours of the Ingenious in many considerable parts of the world." Italy followed with the short-lived *Giornale de' letterati* (Rome, 1668–81)—another journal with the same title was published at Parma from 1668 to 1690 (with a break between 1679 and 1686)—and the *Galleria di Minerva* (Venice, 1696–1717); in Germany the *Acta eruditorum*, published in Latin, appeared in Leipzig from 1682 to 1731. Christian Thomasius' *Monatsgespräche* (1688) was the first periodical in the German language.

Meanwhile the book advertisements in the newsbooks had developed into regular catalogues—of which the *Mercurius librarius* (1668–70) or *Term Catalogues* was the most noteworthy—though these were but "dry things, scarce able to raise in men that gust and appetite for learning" that the *Weekly Memorials for the Ingenious* (1681–83) hoped to foster by means of the critical notes that it attached to each title. This periodical was the precursor of the critical review; it was shortly followed by the *Universal historical bibliothèque* (1686) which announced its intention of printing reviews of important books, and for the first time invited contributions from scholarly critics.

In 1690, Samuel Wesley, father of John and Charles, joined John Dunton in launching the *Athenian Gazette* (later the *Athenian Mercury*, ended 1697), the forerunner of *Notes and Queries* and *Answers*, which attempted a kind of information service on all literary and scientific matters about which its readers might ask. Daniel Defoe was one of the contributors. In 1692 Dunton began to issue supplements dealing with natural history and natural phenomena. Dunton's later journal, *The Compleat Library* (1692–94), virtually the successor of the *Athenian Mercury*, was the first periodical of importance to allot, in the manner now customary in learned journals, definite proportions of its space to original contributions and to book reviews.

Side by side with these attempts to popularize learning were the periodicals of amusement, of which *Mercurius Jocosus* (1654) was one of the earliest, and Donneau de Vizé's *Mercure galant* (Paris, 1672–1820) the most successful. Modeled on the latter, but more serious in content, was P. A. Motteux's *Gentleman's Journal* (1692–94), which contained essays, verses, letters and stories. Edward Ward's *London Spy* (1698–1700), with lively sketches of London manners and customs, was one of a number of short-lived journals whose contents were mainly humourous, vulgar or obscene.

GREAT BRITAIN

If the 17th century saw the establishment of the abstract journal or digest, the learned journal, the critical review and the periodical of amusement, the 18th century produced in the essay periodical its own characteristic contribution to English journalism. This form, itself one of the most important manifestations of 18th-century English literature, constituted the first attempt to create an organized popular opinion in matters of literary taste and manners in general. Richard Steele issued the *Tatler* in 1709–10; and a dozen similar publications appeared in the same year, at least half of them imitating the title as well as the form. Joseph Addison contributed to the *Tatler* and, with Steele, ran its successor the *Spectator* (1711–14) and also the *Guardian* (1713). Swift and Bolingbroke wrote political articles for the *Examiner* (1710–14); the *Spectator* and the *Guardian* replied on behalf of the Whigs, the latter finding itself in no way cramped in this

respect by its early profession of freedom from political controversy.

The Stamp act of 1712 struck a hard blow at the essay periodicals—the *Spectator's* sales dropped from about 4,000 copies to 1,600—but the very severity of the act is striking evidence of their success in forming public opinion not only in the literary but also in the political sphere.

Meanwhile a series of literary reviews—the *History of the Works of the Learned* (1699–1712), the *Memoirs of Literature* (1710–17) and others—carried on the tradition of the *Weekly Memorials for the Ingenious* and the publications of John Dunton. The first Irish review, *A Literary Journal* (Dublin, 1744–46), falls within this period. Of importance was the *Monthly Review* (1749–1844). The first magazine or miscellany of modern type was Edward Cave's *Gentleman's Magazine* (1731–1907), modeled on Motteux's *Gentleman's Journal* of 1692; Samuel Johnson joined the staff in 1738. *The London Magazine or Gentleman's Monthly Intelligencer* (1732–85) was the most formidable of a large number of rivals to the *Gentleman's Magazine;* others were the *Scots Magazine* (1739–1826); the *North Briton,* edited by John Wilkes (1762–63); the *European Magazine and London Review* (1782–1826); and the *Monthly Magazine* (1796–1843). The most noteworthy development of the last few years of the century was the specialized periodical—*Archaeologia* (1770), *Curtis's Botanical Magazine* (1787), the *Philosophical Magazine* (1798) and the *Farmer's Magazine* (1800–25) being among the more important examples, and the first three the longest-lived.

The 19th Century.—To Edinburgh is due the first high-class critical journal, the *Edinburgh Review* (1802–1929), established by Sydney Smith, Henry Brougham and Francis Jeffrey and issued in the buff and blue colours of the Whig party that it supported. Among its more eminent contributors were Carlyle, William Hazlitt and Macaulay. Its brilliant Tory competitor, the *Quarterly Review* (1809), was begun by the London publisher John Murray at the instance of Sir Walter Scott, who, though at first contributing to the *Edinburgh,* soon found himself dissatisfied with it. George Canning, Robert Southey, Lord Salisbury and Gladstone were all contributors to the *Quarterly,* and Scott himself reviewed in it. The third of the famous 19th-century periodicals was *Blackwood's Magazine* (1817), with contributions from Scott, John Lockhart, John Galt and many others. The *Edinburgh* ceased publication with the end of its 250th volume; the *Quarterly* and *Blackwood's* were still current at mid-20th century.

Of other quarterlies may be noted the *Westminster Review* (1824–1914), *Mind* (1876) and a large number of denominational reviews. Among the monthlies and weeklies were the *Christian Observer* (1802–77), the *Monthly Repository* (1806–38), the *Athenaeum* (1828, later combined with *New Statesman and Nation*), the *Spectator* (1828), the *Fortnightly Review* (1865–1950, monthly from 1866), the *Contemporary Review* (1866) and the *Nineteenth Century* (1877, called *Twentieth Century* after 1950). W. T. Stead's *Review of Reviews* (1890–1936) introduced a new development in printing criticisms of work published in other reviews. The *Times* (London) began to issue its *Literary Supplement* in 1902.

The 19th century also produced a flood of popular magazines. John Limburd published the *Mirror* (1822–49) as a twopenny illustrated magazine. A decade later came *Chambers's Journal* (1832), long conducted by the John Chamberses, father and son; the *Penny Magazine* (1832–46), published by Charles Knight; and the *Saturday Magazine* (1832–44), issued by the Society for Promoting of Christian Knowledge. Charles Dickens' *Household Words* (1850–59) was followed by his *All the Year Round* (1859–95); the latter was continued by the novelist's son. Leading sixpenny monthlies were the *Cornhill Magazine* (1860–1939), initially edited by Thackeray and the first to publish serial fiction regularly; *Fraser's Magazine* (1830–82), which published much early Thackeray and some of the best of Thomas Carlyle; and *Temple Bar* (1860–1906), first edited by G. A. Sala. *Notes and Queries* (1849) has long interested the curious antiquary. Nor were the interests of women forgotten: the *Queen* (1861) and the *Lady* (1885) were destined for long lives.

The 20th Century.—The late 19th century saw the birth of the illustrated magazine proper, and the 20th saw its great development. Many magazines had already inserted full-page illustrations and woodcuts in the 1860s, but none of these approached what is now accepted as an illustrated magazine. The continually changing attitude of the public is clearly shown by Sala's statement in *Temple Bar* that, with due regard to the interests of his readers, he preferred to give them 16 extra pages of print rather than an illustration or two. The *English Illustrated Magazine* (1883–1913) may perhaps be considered the parent of illustrated monthlies.

Innumerable publishers forthwith adopted the view of Sir George Newnes that a magazine should give "wholesome and harmless entertainment to crowds of hard-working people craving for a little fun and amusement," by providing light literature and illustrations. The *Strand Magazine* (1891–1950) was designed to "contain stories and articles by the best British writers and special translations of the chief foreign authors." No limit was to be put to illustration. It was a bold move, and even the publishers felt that they were embarking "upon the wildest extravagance in furnishing no fewer than a hundred and ten illustrations in a single number." This was before the general adoption of process engraving, and woodcuts were still in use. The success which followed was phenomenal. In a different category must be placed the illustrated weeklies in which the illustrations counted for more than the letterpress; of these the *Illustrated London News* (1842) was the pioneer. The *Sphere* began in 1900, the *Tatler* in 1901; *Picture Post* (1938–57) was the most striking example at mid-20th century.

Besides illustrations, 20th-century magazines are notable for variety of specialization in the professions, industries, trades, religion, arts and letters, sports, etc. *Radio Times* (1923), which reached a spectacular 9,000,000 circulation by mid-century and continued to rise, was an outstanding example. There were many prosperous motion-picture periodicals, and many devoted to women's interests; the weekly *Woman* (1937) had over 3,000,000 circulation before the end of its second decade.

The outbreak of World War II wrote finis to the files of many periodicals; in 1939 death came to the literary *Criterion* (1922), Sir John Squire's *London Mercury* (1919), and the monthly *Windsor* (1895).

Shortage of paper supply continued to cripple magazine publication for some years after the end of the war.

Children's Magazines.—Another outstanding feature of the late 19th century was the development of literature for the young. Since the spread of education had inspired the production of encyclopaedias and dictionaries expressly intended for the comprehension of children, it is not surprising that periodicals for boys and girls should also have assumed an important role. The best magazines contained a mixture of fiction, science and practical suggestions to young people in a variety of crafts and hobbies. Most prominent of the 19th-century juveniles were *Chatterbox* (1866–1934), *Little Folks* (1871–81), the *Boy's Own Paper* (1879–1904) and the *Girl's Own Paper* (1880). *My Magazine* (1914–33) is a later example.

The so-called "comics" descended upon Britain in mid-20th century like the locusts upon Egypt of old.

Historical and Scientific Magazines.—Though specialized journals began to make their appearance in the late 18th century, it was not until the end of the 19th that any very great expansion of their numbers took place. Mention must be made, however, of a few outstanding earlier examples, such as the *Lancet* (medical; 1823); the *Provincial Medical and Surgical Journal* (1840–52), followed by *British Medical Journal* in 1857; the *Economist* (1843); and *Nature* (general science; 1869). After 1880 every science, art, profession and trade began to issue its own periodical or periodicals until no field of activity, however highly specialized, was unrepresented. It must be sufficient here to list only a few: the *Law Quarterly Review* (1885), the *English Historical Review* (1886), the *Library* (1889), the *Studio* (art; 1893), *Man* (anthropology; 1901), the *Hibbert Journal* (theology and philosophy; 1902).

FRANCE

The *Journal des sçavans*, the first number of which appeared on Jan. 5, 1665, is acknowledged to be the parent of modern periodical literature. About 1663, François Eudes de Mézeray obtained a privilege for a regular literary periodical, but the idea came to nothing; and the credit for having produced the first periodical must go to Denys de Sallo, who at the time was regarded as a genius and inventor for having framed the scheme. Its intention and scope is given in the *Encyclopédie méthodique:* "Il a été inventé pour le soulagement de ceux qui sont ou trop occupés ou trop paresseux pour lire les livres entiers" ("It has been invented for the relief of those who are either too busy or too lazy to read whole books").

The severe literary and political censorship enforced in France was directly responsible for the introduction of the literary periodical into the Netherlands, where no fewer than 31 first-rate journals were issued within the century 1680–1780 by French Protestant refugees.

In this manner appeared Pierre Bayle's *Nouvelles de la république des lettres* (1684–1718), one of the principal successors of the *Journal des sçavans;* and Jean Le Clerc's *Bibliothèque universelle et historique* (1686–93)—to mention only two. A few years later, the *Mémoires pour l'histoire des sciences et des beaux-arts*, commonly known by the name of *Journal de Trévoux* (1701–67), was brought out at Paris under the auspices of the Jesuits. Their primary object was to defend religion from attack, and it was probably for this reason that the journal incurred the displeasure of Voltaire. For 30 years the printers of the little town of Trévoux were kept busy, until it became more convenient to transfer the headquarters of the journal to Paris.

Meanwhile the *Spectator* and *Tatler* were appearing in England; but the French were cautious in adopting the essay periodical, though an incomplete translation of the *Spectator* appeared in Amsterdam in 1714. It was not until 1722 that Marivaux made his unsuccessful attempt to rival the Englishmen by issuing his *Spectateur français* (1722). The *Spectateur suisse* (1723), *Le nouveau Spectateur* (1758) and others came after but were of little value. *Le Pour et contre* (1733–40), edited by the Abbé Prévost and full of anecdote and miscellaneous information, was similar in form to the English reviews.

Another periodical of high rank of the 18th century was the *Journal encyclopédique* (1756–93), founded by Pierre Rousseau, who carried on his work for many years under the protection of the count of Horion, minister of the prince bishop of Liège. When the latter died, Rousseau was compelled to transfer the journal from Liège to Bouillon on account of the philosophical articles it contained, but permission was given him to establish his presses there. Voltaire, Diderot and others contributed to the Paris *Gazette littéraire* from 1764 to 1766. During the revolutionary period, and until the abolition of the censorship in 1828, most periodicals were suspended or suppressed.

Specialized journals began in the latter half of the 17th century and continued in quantity. *Revue des deux mondes* (1829–1944) reached its greatest importance as a fortnightly in mid-19th century, when leading literary figures were contributors. It was succeeded by *Revue: littérature, histoire, arts et sciences des deux mondes* (1948). Other 20th-century reviews are *Nouvelle revue* (1879), *Mercure de France* (1890), *Revue de Paris* (1894) and *Les Oeuvres libres* (1921). *L'Illustration* (1843–1944) was long a world-famous picture magazine. *Paris-match* (1949) quickly gained circulation leadership among French weeklies by brilliant illustration and timely, informative text. Periodicals devoted to women's interests and fashions have also been very successful, as the monthly *Marie-Claire* (1954). Children's periodicals have been popular, as *Le Magasin d'éducation et récréation* (1864–1905), which published Jules Verne and was illustrated by Gustave Doré and J. L. E. Meissonier. "Comics" grew in favour, reaching a distribution of over 20,000,000 monthly at mid-20th century.

GERMANY

The *Acta eruditorum* (Leipzig, 1682–1731), the earliest of German periodicals, was not only limited in its choice of subjects to mathematics, physics and botany, but was also handicapped by the use of the Latin language. Nevertheless, such German men of science as Leibniz and the botanist Michael Ettmüller, combined to make the *Acta* a central meeting ground where the results of their researches might be read. The *Acta* had many imitators. Soon after the English periodicals of Addison and Steele had reached Hamburg, the Germans taking these, especially the *Spectator* and the *Guardian*, as models, brought out *Der Vernünftler* (1713), *Die lustige Fama* (1718) and *Discoursen der Maler* (1721). J. C. Gottsched's *Die vernünftigen Tadlerinnen* (1725–26) was the first women's journal. In 1759 C. F. Nicolai introduced his *Briefe, die neueste Literatur betreffend* to the world, and enlisted as collaborators Lessing and Moses Mendelssohn; it lasted six years. The *Frankfurter gelehrte Anzeigen* (1772–90), a successor of the *Franckfurtische gelehrte Zeitungen* (1736–71), followed a few years later and is chiefly interesting because Goethe wrote for it as a young man; the *Jenaische allgemeine Litteratur-Zeitung*, of which Goethe may be said to have acted as editor in chief, was issued in 1804–41. C. M. Wieland's *Der Teutsche Merkur* (1773–89) stands out as a literary periodical of the first importance, as does also the *Allgemeine Literatur-Zeitung* (1785–1849).

The periodicals issued in the various German states during the next 60 years displayed an ever-increasing political consciousness, and some indeed, such as the *Hallische Jahrbücher* (1838–43), received government support. The *Jahrbücher für wissenschaftliche Kritik* (1827–46), first published by J. F. Cotta, was a noteworthy publication of this period. By the end of the period politics had almost ousted literature from German reviews.

The revolution of 1848 was disastrous to the periodical press, and very few journals survived it. Developments in the later part of the 19th century followed much the same course as in England. Among the best-known journals of this time are the *Deutsche Rundschau* (1874), *Historische Zeitschrift* (1859), *Neue Rundschau* (1889), *Die Literatur* (1898–1942), *Deutsche Vierteljahrsschrift* (1923), *Erkenntnis* (1930–39).

The National Socialist revolution produced a further wave of suppressions, and the division of Germany into zones of occupation in 1945 resulted in many changes and gradual resumption of publication. By the 1950s some 4,000 periodicals were in course of publication. Among reviews were *Deutschland Review* (1949, Hamburg), *Die Besinnung* (1946, Nürnberg) and *Revue* (1948, Munich). *Spiegel* (1947, Hamburg) was a popular weekly; and among picture magazines were *Heute* (1945–51, Munich) and *Zeit und Bild* (1947, Frankfurt).

OTHER COUNTRIES

Canada.—The first monthly in eastern Canada was the *Novia Scotia Magazine* (1789–92), and in Canada proper the *Canadian Magazine* (Montreal, 1823–25). In addition to these were the bilingual *Quebec Magazine* (1791–93), a quarterly; and several others entirely in French: *L'Abeille canadienne* (1818–19), *La Bibliothèque canadienne* (1825–30; continued as *L'Observateur* [1830–31]) and the *Magasin du Bas-Canada* (1832). The *Literary Garland* had a longer life (1838–51) than most of those that preceded it, and was for some time the only English magazine published in Canada. A series of interesting French-Canadian reviews followed; the foremost, *La Revue canadienne* (1864–1922), contained the best writings of contemporary French-Canadian men of letters.

Maclean's Magazine (1896) has long been the best known general magazine in Canada. It is published from Toronto, the country's magazine capital, whence are issued also the *Canadian Home Journal* (1904); and *Chatelaine* (1928), the leading Canadian women's journal. Some U.S. periodicals have large circulations in Canada.

Australia and New Zealand.—The *Australian Magazine* was published in Sydney in 1821–22, and was followed by the *South Asian Register* (1827), the *Australian Quarterly Journal* (1828) and a second *Australian Magazine* (1838). The *Sydney University Magazine* (1855 and 1878–79), continued as the *Sydney University Review*, was of some importance and of literary value. Australian

periodicals are strongest in the weekly field. Greatest of general popular weeklies is the *Bulletin* (1880), founded in Sydney by J. F. Archibald, which became important in the development of the country's literature and art. Largest circulation in the commonwealth was claimed in the late 1950s by the *Australian Women's Weekly* (1933), which had publication offices in all the leading cities and was said to enter one-third of Australian homes.

The Netherlands.—Apart from the journals of French origin already described, the earliest periodicals in the Netherlands were the *Examinator* (1719–20) and *Den Amsterdamschen Hermes* (1722–23). In 1837 *De Gids* was founded as the organ of liberalism and at the same time of a new movement in literature and it remained an important review. *Haagsch Maandblad* (1924) is a literary monthly, and *Erasmus* (1933) an important scientific journal. There are many technical and class periodicals. The official *Radiogids* has a wide circulation.

Italy.—Conditions in Italy were long unfavourable to the growth of periodicals. Politics was not a safe subject for free comment, and the church interfered much in matters of science and literature as well as religion. Nevertheless, the *Journal des sçavans* had its imitator in Rome when Cardinal Ricci began to print *Giornale de' letterati* (1668–81); and Venice, always in the forefront in literary activities, issued the *Galleria di Minerva* (1696–1717). The rivalry, however, of both the academies and the princes acted as a continual curb, and the outlook of editors and writers remained circumscribed for a long period. G. Baretti, in *La Frusta letteraria* (1763–65), so mercilessly attacked the writers of Italy and even the ruling princes that after two years of precarious existence the *Frusta* was suppressed. *Il Caffé* (1764–66) was much influenced by French ideas. Important modern reviews have been *Nuova Antologia* (1866), Benedetto Croce's *La Critica* (1903–44), *Scientia* (1907), *La Rassegna italiana* (1918), *Rinascita* (1944) and *Italia contemporanea* (1953). *Scena Illustrata* (1865) is one of the oldest of illustrated monthlies. *Epoca* (1944) is a popular illustrated weekly.

Portugal.—*Jornal Enciclopedico* (1779–92) and *Jornal de Coimbra* (1812–20) were the chief early Portuguese reviews. *Panorama* was largely historical and literary; Alexandre Herculano's historical tales were published in it. Most 19th-century journals were short-lived; but *Instituto* (1852) had a long life as a literary and scientific review, and *Naturalia* (1936) enjoyed wide acceptance.

U.S.S.R.—In Russia the Academy of Sciences led the way by the issue of *Yezhemyesyatchniya Sochineniya* ("Monthly Works") (1755–64); and four years later the first private undertaking, the *Trudolyubivaya Pchela* ("Industrious Bee") (1759) with critical essays and translations from the *Spectator*, appeared. Few periodicals appeared in Russia until the 19th century, when the most representative magazines were the *Vestnik Evropy* (1802–30), edited by the historian N. M. Karamzin; the *Biblioteka dlya Chteniya* (1834–65), the first to obtain any commercial success; the *Sovremennik* (1836–66), founded by Pushkin; the *Russky Vestnik* (1856–1906), edited by the well-known publicist M. N. Katkov; the *Vestnik Evropy* (1866–1919), a continuation of the earlier *Vestnik*, to which the novelist Turgenev contributed; *Russkaya Misl* (1880–1927); *Letopis* (1915–17), edited by Maksim Gorki. The Bolshevik revolution produced a great upheaval and was responsible for an enormous output of periodicals of all kinds, but without any real freedom of the press. *Novyi Mir* ("New World") (1925) was one of the more important reviews of the Soviet regime. The Soviet publication system calls for the production of a journal in every major field of industry, technology, art. *Literaturnaia Gazetta* (1929) was the leading literary journal. Two periodicals were published from Moscow in English, German and French as well as in Russian—*Soviet Literature* (1932) and *Soviet Woman* (1945).

Scandinavian Countries.—The northern countries of Europe —Sweden, Norway and Denmark—have never lagged behind in the production of literature. The earliest periodical in Sweden was *Swänska Argus* (1732–34), a journal similar to the *Spectator*. Of modern magazines the following are worth mentioning: *Ord och Bild* (1892); *Nordisk Tidskrift* (1878), which prints historical and philosophical articles; *Nya Sverige* (1907–28), a conservative review; and the weekly *Idun* (1888). The first Norwegian periodical was *Ugentlige Korte Afhandlinger* (1760). *Samtiden*, begun by Gerhard Gran in Bergen in 1890 and moved to Oslo a decade later, was long the leading Norwegian journal. *Nye Tidender om lærde Sager* (1720–1837) was the earliest critical journal in Denmark. Leading 20th-century monthlies were *Tilskueren* (1884–1939), *Gads Danske Magasin* (1906), *Danske Magasin* (1952).

Spain.—In Spain the periodical came much later than in France, and it was in the beginning dependent on its French prototype. Political and religious censorship was as severe as it was in Italy. The earliest periodicals date from the middle of the 18th century, the best known being *Efemérides barometricomedicas matritenses* (1743–47) edited by Fernández Navarrete; the *Diario de los literatos de España* (1737–38); and *Memorial literario* (1784–1808).

Three early 19th-century periodicals are worth noting—*Miscelánea de Comercio* (1819), *Artes y literatura* (1819–21) and *El Censor* (1820–22). The influence both of the censorship and of the foreign periodical declined greatly during the regency of Maria Cristina (1833–41). Of a large number of reviews which began in the mid-19th century, mention may be made of the *Revista Ibérica* (1861–63), the *Revista de Cataluña* (Barcelona, 1862–63) and the *Revista de España* (1868–95). *España moderna* (1889–1914), *La Lectura* (1901–20), *Revista de Occidente* (1923–36; first edited by Ortega y Gasset) and *Gaceta literaria* (1927–32) were among the more important periodicals of the first quarter of the 20th century. The outstanding weekly was *Blanco y negro* (1891–1936). The *Revista hispano-americana de ciencias, letras y artes* (1921–36) was one of the better-known reviews of Latin-American interest published in Spain. Many Spanish periodicals fell victims to the strict censorship imposed by the Franco regime. *Mundo Hispánico* (1948) was a later monthly.

Switzerland.—The *Nova litteraria helvetica* (1703–15) of Zürich is the earliest literary periodical which Switzerland can show; followed by the *Bibliothèque italique* (1728–34) and the *Bibliothèque britannique* (1796–1815), both published at Geneva. The *Bibliothèque universelle* (1816) and *Revue suisse* (1838) amalgamated in 1858 as the *Bibliothèque universelle et revue suisse*. Among later periodicals may be mentioned *Revue mensuelle* (1897–1926); *Zwingliana* (1897); *Archives de psychologie de suisse romande* (1901) edited by Flournoy and Claparède; *Untersuchungen zur neueren Sprach- und Literaturgeschichte* (1903–12); *Revue de Genève* (1920–24); and *Schweizerische Monatshefte* (1921). In the second half of the 20th century, leading monthlies were *Atlantis* (1929), *Schweitzer Journal* (1935) and *Gegenwart* (1939); and leading weeklies were *Schweitzer familien-Wochenblatt* (1881), *Patrie suisse* (1884), *Schweitzer illustrierte Zeitung* (1912) and *Weltwoche* (1933).

India.—The first Indian magazine was the *Oriental Magazine, or Calcutta Amusement* (1785–86). Several periodicals were conducted, usually for brief periods, by western missionaries. The *Hindustan Review* (1900, Patna) was founded and long edited by Sachschudananda Sinha, at Allahabad. The *Indian Review* (1900, Madras) was established by G. A. Natesan. In the course of India's economic development of the mid-20th century, a large number of professional, technical and industrial periodicals sprang up.

South Africa.—The *South African Journal* (1824, Cape Town) was the pioneer journal of this region. The periodicals of South Africa are chiefly centred in Cape Town and Johannesburg, and are largely trade and industrial journals of 20th-century growth.

Japan.—The Meiji restoration of 1868 brought a renaissance of culture and popular education in Japan and marked the beginning of magazines as distinct from newspapers. In the early 20th century the leading figure in the publication of Japanese magazines was Noma Seiji, whose nine periodicals nearly all had reached circulation in six figures. Many of the country's leading magazines survived World War II; and by the end of the occupation in 1952 there were more than 2,000 periodicals in course of publication, including popular miscellanies, women's journals, an interesting class of light literary reviews, magazines for youth and periodicals devoted to the stage, screen, radio, television and sports.

There was a large group of small magazines devoted to verse. Weekly news magazines issued by leading newspapers had large circulations. Outstanding class periodicals were *Shufu No Tomo* ("Woman's Friend," 1917), *Yoiko No Tomo* ("Child's Friend," 1924) and *Shin Eiga* ("New Movies," 1938).

China.—The Christian missionaries William Milne, Robert Morrison and Liang A-fa established the first successful Chinese general magazine, under the title *Tsachihshu Maiyueh Tungchichuan* ("Chinese Monthly Magazine"). Printed in Malacca, it was circulated in Chinese territory (1815–22). The first to be published in China itself came from Canton in 1833, was moved to Singapore four years later and published there for a decade; it was called *Tunghsiyankao Maiyueh Tungchichuan* ("Eastern-Western Monthly Magazine") and was founded by Charles Gutlaff, a missionary, but in 1837 it was taken over by the Society for the Diffusion of Useful Knowledge, a British institution. Various and numerous periodicals offering religious, philosophical, literary and scientific matter were published in the chief Chinese cities in the 19th century; but it was not until the period of Liang Ch'i-ch'ao and his fellow reformers and publicists, beginning in the second decade of the 20th century, that modern periodicals came into wide circulation. Liang himself was editor, usually for brief periods, of eight different periodicals. Among long-lived magazines were *Tung-fang Tsa-chih* ("Eastern Miscellany," 1904) and *Chiao-yü Tsa-chih* ("Educational Miscellany," 1908). The Communist revolution of 1949 resulted, after a few years, in wider distribution of periodicals than formerly; but these were controlled by the government and highly propagandist.

Central and South America.—Early gazettes and journals in Central and South American countries often partook of the nature of magazines, being miscellaneous in character; but not until the 20th century did periodicals as such flourish. By that time colour printing had been well developed, and illustrated weeklies and monthlies were widely popular. The largest Cuban magazine was the attractively illustrated *Bohemia* (1911), a weekly. In Mexico the leader was *La Familia* (1931), a fortnightly. In Brazil were two outstanding magazines in the Portuguese language—*Eu Sei Tudo* (1920), a general monthly; and *Vida Domestica* (1920), a women's journal. Argentina had many more magazines than any other South American country, as well as wider readership. *Maribel* (1932), rotogravure weekly miscellany, boasted at mid-20th century a larger circulation than any other South American magazine, though *Para Ti* (1922), also of Buenos Aires, a women's weekly, was a close second. (C. T. H. W.; F. L. K.; F. L. Mt.).

UNITED STATES

The first American magazines were two Philadelphia, Pa., publications that dated their first numbers Jan. 1741. Actually first to appear was Andrew Bradford's *American Magazine*, followed in three days by Benjamin Franklin's *General Magazine*. The former lasted three months and the latter six. About 100 magazines were founded in the Colonies, most of them very short-lived. Outstanding were three Philadelphia periodicals—the *Pennsylvania Magazine* (1775–1776), edited by Thomas Paine; the *Columbian Magazine* (1786–92), called the *Universal Asylum* in its last two or three years; and Mathew Carey's *American Museum* (1787–92). Also important were Isaiah Thomas' *Royal American Magazine* (1774–75) and *Massachusetts Magazine* (1789–96); and Thomas and James Swords' *New-York Magazine* (1790–97).

More than 500 periodicals were published for shorter or longer periods in the first quarter of the 19th century; nearly 100 were being issued in 1825. There was marked development in weekly miscellanies supported by literary coteries in many cities and towns; in periodicals for women and children; in religious journals and those devoted to such reforms as antislavery and temperance; in medical, legal and agricultural journals; and in theatrical and comic papers. This class journalism increased rapidly and by mid-19th century there were about 600 periodicals.

Outstanding monthlies were *Godey's Lady's Book* (1830–98, Philadelphia), famous for its stenciled coloured fashion plates; *Graham's Magazine* (1826–58, Philadelphia), which began as the *Casket;* the *Southern Literary Messenger* (1834–64, Richmond, Va.); and the *Knickerbocker Magazine* (1833–65, New York city). Chief quarterlies were the *North American Review* (1815–1940), which developed from the *Monthly Anthology* (1803–11, Boston, Mass.) and had a famous line of editors, including Jared Sparks, Edward Everett, James Russell Lowell, Henry Adams, and George B. M. Harvey; *The Dial* (1840–44), famous transcendental magazine edited by Margaret Fuller, Thoreau and Emerson; and *De Bow's Review* (1846–80, New Orleans, La.). Notable weeklies were the *Youth's Companion* (1827–1929), a family periodical with a long line of famous contributors; and the *Saturday Evening Post,* founded in 1821, but brought to its later preeminence as a popular weekly after its purchase by Cyrus H. K. Curtis in 1897.

A New Era, 1850.—A new era began with the founding of *Harper's New Monthly Magazine* in New York city in 1850, with copious woodcut illustration, 144 pages and English fiction serials. A worthy competitor came in 1870, *Scribner's Monthly*, later the *Century* (1881–1930). *Scribner's Magazine* (1887–1939) was another quality illustrated monthly. By 1890 these richly illustrated general magazines surpassed anything of the kind ever before known in any country. The *Atlantic Monthly*, Boston, without illustrations, began its distinguished literary career in 1857, under Lowell's editorship. William Dean Howells, Thomas Bailey Aldrich, Walter Hines Page and Ellery Sedgwick were among its editors. Other famous monthlies of the latter 19th century were the *Galaxy* (1866–78), New York; *Overland Monthly* (1868–1935), San Francisco, whose first editor was Bret Harte; *Forum* (1886–1940), New York; *Lippincott's Magazine* (1868–1916), Philadelphia; and *Frank Leslie's Popular Monthly*, New York, which began in 1876 and from 1906 to 1956 was published as the *American Magazine*. Three prominent New York weeklies were *Harper's Weekly* (1857–1916); *The Nation*, founded by Edwin Lawrence Godkin in 1865; and *Outlook* (1870–1935), which began as *Christian Union* under Henry Ward Beecher's editorship. By 1870 there were about 1,200 periodicals in the United States, close to 2,400 in 1880, and nearly 3,000 by 1890.

In the 1890s came the high-class illustrated monthlies selling for 10 or 15 cents in place of the 35 cents asked by the "quality" magazines. The only one of this spectacular group to survive was the *Cosmopolitan,* founded in 1886 by John Brisben Walker; others were *McClure's Magazine* (1893–1933), *Munsey's Magazine* (1889–1929) and *Everybody's Magazine* (1899–1929). These, with the *Arena* (1889–1909), of Boston, and the weekly *Collier's* (1888–1957), were leaders in the muckraking which exposed corruption in municipal government, finance, etc., throughout the decade 1902–12. Leading muckrakers for *McClure's* were Lincoln Steffens, Ida M. Tarbell and Ray Stannard Baker, who later took over the ailing *Frank Leslie's Popular Monthly* and renamed it the *American Magazine*.

Later Magazines.—The *Reader's Digest,* a pocket-size magazine containing condensations of articles from other periodicals, was founded in 1922 and by mid-century had attained the largest circulation of any serial publication ever known, said to be about 21,000,000 monthly, including editions distributed in most foreign countries and printed in several foreign languages. *Time*, a weekly news magazine founded in 1923 by Briton Hadden and Henry R. Luce, met with much success and had a considerable effect on the art of reporting. *Newsweek* (founded 1933) was the most successful of its followers. In 1936 Time, Inc., launched a weekly picture magazine whose title, *Life*, was purchased from the satirical weekly (founded 1883) which had just suspended publication. Another picture magazine, the fortnightly *Look*, was founded in 1937. In the 1960s both had circulations of about 7,000,000. (*See* also PHOTOJOURNALISM.) *The New Yorker,* founded in 1925 by Harold Ross, though smaller in circulation (about 440,000 in the 1960s), had great influence on fiction writing, reporting, and cartooning. Prominent among U.S. periodicals in the 20th century were illustrated magazines for women, such as *Ladies' Home Journal* (founded 1883), *Harper's Bazaar* (founded 1867), *Woman's Home Companion* (1873–1957), *Good Housekeeping* (founded 1885), *Vogue* (founded 1892) and *Better Homes and Gardens* (founded 1922).

Most U.S. general periodicals are circulated largely by subscription, the price usually being lower than the cost of publication; such magazines therefore depend for their financing upon advertising revenue. (An exception was the *Reader's Digest*, which until 1955 did not accept any advertising.) With the advent of other advertising media, particularly television, the proportion of advertising budgets spent for printed media tended to decline. This loss of revenue, combined with changes in reading habits, increasing production expenses, and increases in postage rates, created serious problems for many large-circulation general magazines. *See* also LITTLE MAGAZINE and references under "Periodical" in the Index.

PERIODIC LAW. Dmitri I. Mendeléyev discovered in the mid-19th century that the chemical elements show a periodic recurrence of properties when they are arranged in a certain order, which is approximately the order of increasing atomic weight. The statement of this fact, which has been of inestimable value in the development of the science of chemistry, is called the periodic law; and a tabular arrangement of the elements which brings those with similar properties into juxtaposition is called the periodic table or periodic system of the elements.

It was recognized during the second decade of the 20th century that the order of elements in the periodic system is that of their atomic numbers, the integers which are equal to the positive electrical charges of the atomic nuclei expressed in electronic units; and in recent years great progress has been made in explaining the periodic law in terms of the electronic structure of atoms and molecules. This clarification has increased the value of the law, which is used as much today as it was at the beginning of the 20th century, when it expressed the only known relationship among the elements.

History of the Periodic Law.—The classification of the chemical elements is a comparatively recent problem, for it was not until about the beginning of the 19th century that the two kinds of chemical substances, elements and compounds, were clearly differentiated. The early years of the century witnessed a rapid development in analytical chemistry—the art of distinguishing different chemical substances—and the consequent building up of a vast body of knowledge of the chemical and physical properties of both elements and compounds. This rapid expansion of chemical knowledge soon necessitated classification, for on the classification of chemical knowledge are based not only the systematized literature of chemistry but also the laboratory arts by which chemistry is passed on as a living science from one generation of chemists to another. The elementary substances are few in number, about 100, with distinctive properties, whereas compound substances are extremely numerous, with properties correspondingly diversified and often overlapping. It thus occurred that the classification of elements lagged many years behind that of compounds, and, in fact, no general agreement had been reached among chemists as to the classification of elements for nearly half a century after the systems of classification of compounds had become established in general use.

J. W. Döbereiner in 1817 showed that the combining weight of strontium lies midway between those of calcium and barium, and some years later he showed that other such "triads" exist (chlorine, bromine and iodine; and lithium, sodium and potassium). J. B. A. Dumas, L. Gmelin, E. Lenssen, Max von Pettenkofer and J. P. Cooke expanded Döbereiner's suggestions between 1828 and 1854 by showing that similar relationships extended further than the triads of elements, fluorine being added to the halogens, and magnesium to the alkaline-earth metals, while oxygen, sulfur, selenium and tellurium were classed as one family and nitrogen, phosphorus, arsenic, antimony and bismuth as another family of elements.

Attempts were subsequently made to show that the atomic weights of the elements could be expressed by an arithmetical function, and in 1862 A. E. B. de Chancourtois proposed a classification of the elements based on the new values of atomic weights given by Stanislao Cannizzaro's system of 1858. De Chancourtois plotted the atomic weights on a helical curve such that corresponding points differed by 16, the approximate atomic weight of oxygen. This curve brought closely related elements onto corresponding points, and he suggested in consequence that "the properties of the elements are the properties of numbers," a remarkable prediction in the light of modern knowledge.

In the following year, 1863, J. A. R. Newlands proposed a system of classification of the elements in the order of atomic weights, the elements being assigned ordinal numbers from unity upward and divided into seven groups having properties closely related to the first seven of the elements then known: hydrogen, lithium, beryllium, boron, carbon, nitrogen and oxygen. This relationship was termed the law of octaves, by analogy with the seven intervals of the musical scale.

TABLE I.—*The Short-Period Form of the Periodic System of the Elements*

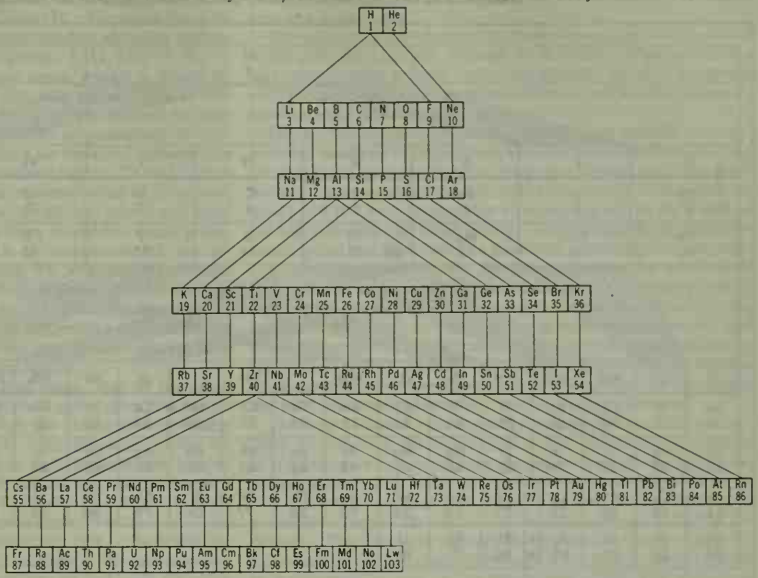
*Lantbanum and the lanthanons.

Then in 1869 Mendeléyev, as a result of an extensive correlation of the properties and the atomic weights of the elements, with special attention to valency, proposed the periodic law, by which "the elements arranged according to the magnitude of atomic weights show a periodic change of properties." Lothar Meyer had independently reached a similar conclusion, published after the appearance of Mendeléyev's Russian paper and of an account of it in German.

Mendeléyev's periodic table of 1869 contained 17 columns, with two nearly complete periods (sequences) of elements, from potassium to bromine and rubidium to iodine (*see* Table III), preceded by two partial periods of seven elements each (lithium to fluorine and sodium to chlorine), and followed by three incomplete periods. In his 1871 paper Mendeléyev presented a revision of the 17-group table, the principal improvement being the correct repositioning of 17 elements. He, as well as Lothar Meyer, also proposed a table with eight columns, obtained by splitting each of the long periods into a period of seven, an eighth group containing the three central elements (such as iron, cobalt, nickel; Mendeléyev also included copper, instead of placing it in group I), and a second period of seven. The first and second periods of seven were later distinguished by use of the letters "a" and "b" attached to the group symbols, which were the Roman numerals.

TABLE II.—*The Periodic System of the Elements With Periods Demarcated by the Noble Gases*



With the discovery of the noble gases helium, neon, argon, etc., by Lord Rayleigh and Sir William Ramsay in 1894 and the following years, Mendeléyev and others proposed that a new "zero" group to accommodate them be added to the periodic table. The "short-period" form of the periodic law, with groups 0, I, II, . . . VIII, became popular, and remained in general use until recent years.

A new table, devised in 1895 by J. Thomsen, was interpreted in terms of the electronic structure of atoms by Niels Bohr in 1922. In this table, Table II, there are periods of increasing length, each extending from one noble gas to the next noble gas; the table thus contains a period of 2 elements, two periods of 8 elements, two periods of 18 elements, a period of 32 elements and an incomplete period. The elements in each period are connected by tie-lines with corresponding elements in the following period. The principal disadvantage of this periodic table is the large space required by the period of 32 elements and the difficulty of tracing a sequence of closely similar elements along the slanting tie-lines. A very satisfactory compromise, shown in Table III, is to compress the period of 32 elements into 18 spaces by omitting the 14 rare earths, or lanthanons, which are indicated below. This form of the periodic table is the work of T. Bayley (1882).

The great value of the periodic law was made evident by Mendeléyev's success in 1871 in finding that the properties of 17 elements could be correlated with those of other elements by moving the 17 to new positions from those indicated by their atomic weights. This change indicated that there were small errors in the previously accepted atomic weights of several of the elements, and large errors for several others, for which wrong multiples of the combining weights had been used as atomic weights. Mendeléyev was also able to predict the existence and many of the properties of the undiscovered elements eka-boron, eka-aluminum, eka-silicon, now identified with the elements scandium, gallium, germanium, respectively. Similarly, after the discovery of helium and argon, the periodic law permitted the prediction of the existence of neon, krypton, xenon and radon. Moreover, Bohr pointed out that element 72 would be expected, from its position in the periodic system, to be similar to zirconium in its properties rather than to the rare earths; this observation led G. de Hevesy and D. Coster in 1922 to examine zirconium ores and to discover the missing element, which they named hafnium.

Many of the elements in the Mendeléyev and Lothar Meyer periodic tables of 1871 were required by their properties to be put in positions somewhat out of the order of atomic weights. Most of these displacements have been rectified by redeterminations of the atomic weights; three, however, remain, and are real. In the three pairs of elements argon and potassium, cobalt and nickel, and tellurium and iodine, the first element of each pair has the greater atomic weight, but the earlier position in the periodic system. The solution of this difficulty had been indicated by Newlands, who had assigned the successive ordinal numbers to the elements arranged approximately according to atomic weight.

Ernest Rutherford's experiments on the scattering of alpha particles by the nuclei of heavy atoms led to the determination of the nuclear electrical charge. The ratio of the nuclear charge to that of the electron was noted to be roughly one-half the atomic weight. In 1911 A. van den Broek suggested that this quantity, the atomic number, might be identified with the ordinal number of the element in the periodic system. This suggestion was brilliantly confirmed in 1913 by H. G.-J. Moseley's measurements of the wave lengths of the characteristic X-ray spectral lines of many elements. There is no longer any uncertainty about the position of any element in the ordered series of the periodic system. All of the elements from 1 to 103 are now known, and it is to be expected that new elements beyond 103 will be made by nuclear reactions.

The small significance of the exact atomic weight of an element to its position in the periodic system is shown by the existence of isotopes of every element, atoms which have the same atomic number but different atomic weights. The chemical properties of the different isotopes of an element are essentially the same, and all of the isotopes of an element occupy the same place in the periodic system.

The detailed understanding of the periodic system has developed along with the quantum theory of spectra and the electronic struc-

ture of atoms, beginning with the work of Bohr in 1913. Important forward steps were the formulation of the general rules of the old quantum theory by W. Wilson and A. Sommerfeld in 1917, the discovery of the exclusion principle by W. Pauli, Jr., in 1925, the discovery of the spin of the electron by G. E. Uhlenbeck and S. Goudsmit in 1925, and the development of quantum mechanics by W. Heisenberg and E. Schrödinger during the same year. The development of the electronic theory of valence and molecular structure, beginning with the postulate of the shared electron pair by G. N. Lewis in 1916, also played a very important part in explaining the periodic law.

Mendeléyev stated that a natural law acquires scientific importance only when it yields practical results in elucidating unexplained phenomena, in disclosing unrecognized occurrences and in evoking verifiable predictions. The periodic law has been found to be very useful indeed in the simplification of the science of chemistry through the classification of the elements; in the determination of the correct multiples of equivalent weights to be taken as the atomic weights of elements; in indicating errors in atomic weights; in the prediction of the existence and properties of new elements; and especially as a basis for chemical reasoning and prediction in the planning of experimental work. Its value has increased with increasing understanding of the law and its basis in the electronic structure of atoms.

Survey of the Elements in Relation to the Periodic System.—The long-period form of the periodic system, Table III, is used as the basis of the discussion that follows. This table has the great advantage over the short-period form, Table I, in that it does not confuse the user by placing in the same group such dissimilar elements as the halogens and manganese and its congeners. It is also more useful and in some respects more satisfactory than Table II, the periodic system with groups demarcated by the noble gases. In particular, the condensation of the very long period, cesium, 55, to radon, 86, by the omission of the rare-earth metals permits the closely related elements such as copper, silver and gold to be placed close together in a compact column.

The long-period form of the periodic system of the elements, Table III, contains all the chemical elements that have been discovered or made; they are arranged, in the order of their atomic numbers, in seven horizontal periods, with the rare-earth metals (cerium, 58, to lutecium, 71) and the actinons (thorium, 90, to lawrencium, 103) indicated separately below. The periods are of varying lengths. First, there is the hydrogen period, consisting of the two elements hydrogen, 1, and helium, 2. Then there are two periods of eight elements each: the first short period, from lithium, 3, to neon, 10; and the second short period, from sodium, 11, to argon, 18. There follow two periods of 18 elements each: the first long period, from potassium, 19, to krypton, 36; and the second long period, from rubidium, 37, to xenon, 54. The very long period of 32 elements, from cesium, 55, to radon, 86, is condensed into 18 columns by the omission of the 14 lanthanons (which are indicated separately below), permitting the remaining 18 elements, which are closely similar in their properties to corresponding elements of the first and second long periods, to be placed directly below these elements. The last period, extending from francium, 87, to lawrencium, 103, is incomplete. The properties of these elements indicate that this period is a second very long period of 32 elements. The elements from thorium to uranium are indicated in the table in two places: first, below the elements hafnium to tungsten respectively, to which they show considerable similarity in properties; and second, below the corresponding lanthanons.

The six noble gases, helium, neon, argon, krypton, xenon and radon, occur at the ends of the six completed periods and consti-

tute the 0 group of the periodic system. For convenience, this group is repeated at the left side of Table III. The seven elements lithium to fluorine and the seven corresponding elements sodium to chlorine are placed in the seven groups, I, II, III, IV, V, VI and VII, respectively. Each of these seven groups is joined by tie-lines with two elements of the first long series. The 17 elements from potassium, 19, to bromine, 35, are distinct in their properties, and might well be considered to constitute 17 subgroups of the periodic system. Largely for historical reasons (the use of the short-period form of the periodic system, Table I), however, it is customary to describe them as constituting 15 subgroups, the three consecutive elements iron, cobalt and nickel and their congeners in the succeeding periods being placed in a single group, VIII. The elements potassium, 19, to manganese, 25, are assigned to subgroups Ia, IIa, IIIa, IVa, Va, VIa and VIIa respectively; and the elements copper, 29, to bromine, 35, are assigned to subgroups Ib to VIIb, respectively. (In some modern versions of the periodic system, the members of subgroups a and b in groups III and above are the reverse of the arrangement shown here. There is no one standard form of the system.)

It is customary to consider the first group, that of the alkali metals, as including, in addition to lithium and sodium, the metals of subgroup Ia (potassium, etc.), but not the much less similar metals of subgroup Ib (copper, etc.). Also the second group, the alkaline-earth metals, is considered to include beryllium, magnesium, calcium, strontium, barium and radium, but not the elements of subgroup IIb. The properties of the elements do not indicate unambiguously whether the boron group might be better considered to include the subgroup IIIa or the subgroup IIIb. The other four groups include the corresponding "b" subgroups: the carbon group, IV, consists of carbon, silicon, germanium, tin and lead; the nitrogen group, V, includes nitrogen, phosphorus, arsenic, antimony and bismuth; the oxygen group, VI, includes oxygen, sulfur, selenium, tellurium and polonium; and the halogen group, VII, includes fluorine, chlorine, bromine, iodine and astatine. The proposed inclusion of potassium and its congeners with lithium and sodium as group I is indicated in the table by representing the subgroup by the symbol I(a), and similarly for II(a), IV(b), V(b), VI(b) and VII(b). The ambiguity for group III, which is considered by about equal numbers of authorities to include scandium and its congeners, on the one hand, and gallium and its congeners, on the other, is not resolved in this table.

Hydrogen is indicated by tie-lines to be related to both the alkali-metal group and the halogen group. In its chemical properties it is not closely similar to either the alkali metals or the halogens. However, it is assigned the oxidation number $+1$ in its compounds such as HF, and -1 in its compounds such as LiH; and it may hence be considered as being similar to a group I element and to a group VII element, respectively, in compounds of these two types, taking the place first of Li and then of F in LiF. Hydrogen is, in fact, the most individualistic of the elements: no other element resembles it in the way that sodium resembles lithium, chlorine resembles fluorine, and neon resembles helium. It is a unique element, the only element that cannot conveniently be considered a member of a group.

Ten of the elements of each long period are called the transition metals. There are usually taken to be scandium, 21, to zinc, 30 (the iron-group transition metals); yttrium, 39, to cadmium, 48 (the palladium-group transition metals); and hafnium, 72, to thallium, 81 (the platinum-group transition metals).

The periodicity in properties of the elements arranged in order of atomic number is strikingly shown by the consideration of the physical state of the elementary substances and such related properties as the melting point, density and hardness. The elements of group 0 are gases that are difficult to condense. The alkali metals, in group I, are soft, metallic solids with low melting points. The alkaline-earth metals, in group II, are harder and have higher melting points than the adjacent alkali metals. The hardness and melting point continue to increase through groups III and IV, and then decrease through groups V, VI and VII. The elements of the long periods show a gradual increase in hardness and melting point from the beginning alkali metals to the centre of the period (cobalt, rhodium, iridium), and then a fairly regular decrease to the halogens and noble gases.

The valence of the elements is closely correlated with position in the periodic table, the elements in the principal groups having maximum positive valence (oxidation number) equal to the group number; and maximum negative valence equal to the difference between eight and the group number.

The general chemical properties described as metallic or base-forming, metalloid or amphoteric, and nonmetallic or acid-forming are correlated with the periodic table in a simple way: the most metallic elements are to the left and to the bottom of the periodic table; and the most nonmetallic elements are to the right and to the top (ignoring the noble gases). The metalloids are adjacent to a diagonal line from boron to polonium. A closely related property is electronegativity, the tendency of atoms to retain their electrons and to attract additional electrons, as shown by ionization potential, electron affinity, oxidation-reduction potential, the energy of formation of chemical bonds with other elements and other properties. The electronegativity depends upon position in the periodic table in the same way as nonmetallic character, fluorine being the most electronegative element and cesium (or francium) the least electronegative (most electropositive) element.

The sizes of atoms vary regularly through the periodic system. Thus the effective bonding radius in the elementary substances in crystalline or molecular form decreases through the first short period from 1.52 Å (angstrom unit $= 10^{-8}$ cm.) for lithium to 0.73 Å for fluorine, then rises abruptly to 1.86 Å for sodium, and gradually decreases through the second short period to 0.99 Å for chlorine. The behaviour through the long periods is more complex: the bonding radius decreases gradually from 2.31 Å for potassium to a minimum of 1.25 Å for cobalt and nickel, and then rises slightly, and falls to 1.14 Å for bromine. The sizes of atoms are of importance in the determination of co-ordination number, and hence of the composition of compounds. The increase in atomic size from the upper right corner of the periodic table to the lower left corner is reflected in the formulas of the oxygen acids of the elements in their highest states of oxidation, as shown in Table IV.

TABLE IV.—*Formulas of Oxygen Acids of Elements in Their Highest Oxidation State*

$H_2Be(OH)_4$	H_3BO_3 $HAl(OH)_4$	H_2CO_3 H_4SiO_4 H_2GeO_4 $H_2Sn(OH)_6$	HNO_3 H_3PO_4 H_3AsO_4 $HSb(OH)_6$	H_2SO_4 H_2SeO_4 H_6TeO_6 and H_2TeO_4	$HClO_4$ HIO_4 and H_5IO_6

The smallest atoms group only three oxygen atoms about themselves; the next larger atoms, which co-ordinate a tetrahedron of four oxygen atoms, are in a diagonal belt; and the still larger atoms, which form octahedral oxygen complexes (stannic acid, antimonic acid, telluric acid, paraperiodic acid), lie below and to the left of this belt. It is only the chemical and physical properties of the elements that are determined by the extranuclear electronic structure; these properties show the periodicity described in the periodic law. The properties of the atomic nuclei themselves, such as the magnitude of the packing fraction and the power of entering into nuclear reactions, are, although dependent upon the atomic number, not dependent in the same periodic way.

The Electronic Structure of Atoms as the Basis of the Periodic System.—The noble gases, helium, neon, argon, krypton, xenon and radon, have a striking chemical property—that of forming few chemical compounds. It would be surmised that this property depends upon their possession of especially stable electronic structures. During the development of modern atomic physics and the theory of quantum mechanics, a precise and detailed understanding has been obtained of the electronic structure of the noble gases and other atoms that explains the periodic law in a thoroughly satisfactory manner.

The Pauli exclusion principle states that no more than two electrons can occupy the same orbit (or, in wave-mechanical language, orbital) in an atom, and that these two electrons in the same orbital must be paired; that is, must have their spins opposed. The orbitals in an atom may be described by a total quantum number,

n, which may assume the values 1, 2, 3, . . . ; and an azimuthal quantum number, l, which may assume the values 0, 1, 2, . . . , $n - 1$. There are $2l + 1$ distinct orbitals for each set of values of n and l. The most stable orbitals, which bring the electron closest to the nucleus, are those with the smallest values of n and l. The electrons that occupy the orbital with $n = 1$ (and $l = 0$) are said to be in the K shell of electrons; the L, M, N, . . . shells correspond respectively to $n = 2, 3, 4, \ldots$. Each shell except the K shell is divided into subshells corresponding to the values 0, 1, 2, 3, . . . of the azimuthal quantum number l; these subshells are called the s, p, d, f, . . . subshells, and they can accommodate a maximum of 2, 6, 10, 14, . . . electrons.

The approximate order of stability of the successive subshells in an atom is indicated in Table V. The most stable shell, the K shell, is completed at helium, with two electrons. The L shell is then completely filled at neon, with atomic number 10. The atoms of the heavier noble gases do not, however, have a completed outer shell, but instead have completed s and p subshells; *i.e.*, an outer shell of eight electrons, called an octet of electrons. The d subshells and f subshells are also filled with electrons after the less stable orbitals are occupied.

The electron occupancy of the shells in the noble gas atoms is:

Electrons in		K	L	M	N	O	P	Q	shell
He	2:	2							
Ne	10:	2	8						
Ar	18:	2	8	8					
Kr	36:	2	8	18	8				
Xe	54:	2	8	18	18	8			
Rn	86:	2	8	18	32	18	8		
	118:	2	8	18	32	32	18	8	

The numbers 2, 8, 18 and 32 correspond to filling the s; s and p; s, p and d; and s, p, d and f subshells, respectively.

The first period of the periodic table is complete at helium, when the K shell is filled with two electrons. The first and second short periods represent the filling of the 2s and 2p subshells (completing the L shell at neon), and the 3s and 3p subshells (at argon), leaving the M shell incomplete. The first long period begins by the introduction of electrons in the 4s orbital. Then at scandium the five 3d orbitals of the inner M shell begin to be occupied. It is the successive occupancy of these five 3d orbitals by their complement of ten electrons that characterizes the ten elements of the iron-group transition series. At krypton the M shell is complete and there is an octet in the N shell. The second long period, of 18 elements, similarly represents the completion of an outer octet and the next inner subshell of 10d electrons.

The very long period of 32 elements results from the completion of the 4f subshell of 14 electrons, the 5d subshell of 10 electrons, and the 6s, 6p octet. The filling of the 4f orbitals corresponds to the sequence of 14 lanthanons, and that of the 5d orbitals to the 10 platinum-group transition metals.

The next period, which is incomplete, involves the 5f subshell of 14 electrons, the 6d subshell of 10 electrons, and the 7s, 7p octet. The filling of the 5f orbitals corresponds to the actinons, the elements beginning with thorium, 90.

The successive periods of the system hence correspond to the introduction of electrons into the following orbitals:

The very short period, H, He.	2 elements. 1s.
The first short period, Li to Ne.	8 elements. 2s, 2p.
The second short period, Na to Ar.	8 elements. 3s, 3p.
The first long period, K to Kr.	18 elements. 3d, 4s, 4p.
The second long period, Rb to Xe.	18 elements. 4d, 5s, 5p.
The very long period, Cs to Rn.	32 elements. 4f, 5d, 6s, 6p.
The incomplete period, Fr to 118.	32 elements. 5f, 6d, 7s, 7p.

There are advantages to replacing the K, L, M, . . . shells by a different grouping of the subshells, in which those with nearly the same energy are grouped together, in close correlation with the periodic system. The new set of shells is the following:

The helium shell.	2 electrons. 1s.
The neon shell.	8 electrons. 2s, 2p.
The argon shell.	8 electrons. 3s, 3p.
The krypton shell.	18 electrons. 4s, 4p, 3d.
The xenon shell.	18 electrons. 5s, 5p, 4d.
The radon shell.	32 electrons. 6s, 6p, 5d, 4f.
The eka-radon shell.	32 electrons. 7s, 7p, 6d, 5f.

(*See* CHEMISTRY: *Inorganic Chemistry: Group VIII, the Rare Gases.*)

The Properties of the Elements of the Main Groups.—The periodicity of properties of the elements is caused by the periodicity in electronic structure. The noble gases are chemically unreactive or nearly so because their electronic structures are stable—their atoms hold their quota of electrons strongly, have no affinity for more electrons, and have little tendency to share electrons with other atoms. An element close to a noble gas in the periodic system, on the other hand, is reactive chemically because of the possibility of assuming the stable electronic configuration of the noble gas, by losing one or more electrons to another atom, by gaining one or more electrons from another atom, or by sharing electrons. (*See* VALENCE.) The alkali metals, in group I, can assume the noble-gas configurations by losing one electron, which is loosely held in the outermost (valence) shell, to another element with greater electron affinity, thus producing the stable singly charged positive ions. Similarly the alkaline-earth metals can form doubly charged positive ions with the noble-gas electronic configurations by losing the two loosely held electrons of the valence shell; the positive ionic valences of the elements of the first groups are hence equal to the group numbers. The elements just preceding the noble gases can form negative ions with the noble gas configurations by gaining electrons; the negative ionic valences of these elements are equal to the difference between eight and their group numbers. The covalence of an atom is also determined by its electron number and the stable orbitals available to it. An atom, such as fluorine, with seven electrons in its outer shell can combine with a similar atom by sharing a pair of electrons with it, thus achieving the noble-gas configuration, with three unshared pairs and one shared electron pair in the valence shell.

The properties of elements in the same group of the periodic system are, although similar, not identical. The trend in properties from the lighter to the heavier elements may be attributed to changes in the strength of binding of the outer electrons and especially to the increasing size of the atoms.

The Transition Elements.—The nature of the three transition groups can be discussed by taking the iron group as an example, since the other two groups are similar.

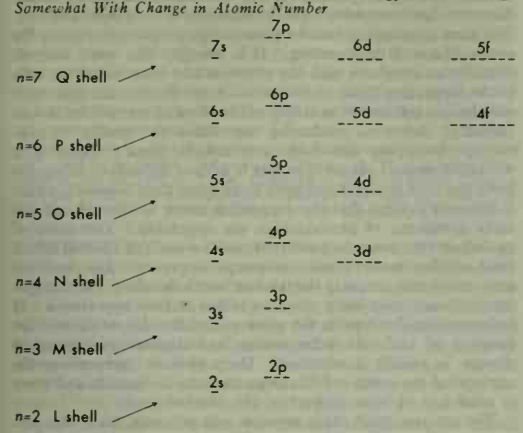
In potassium and calcium the valence electrons, outside of the argon shell, occupy the 4s orbital. Additional valence electrons, in scandium, titanium, etc., enter not the 4s subshell but the 3d subshell, which is then completely filled, along with 4s, in zinc. The elements potassium, calcium, scandium, titanium, vanadium, chromium and manganese have maximum oxidation numbers that range from one to seven, in that order, corresponding to their successive positions following argon. The atoms titanium to manganese are, however, not similar to the corresponding atoms carbon to fluorine or silicon to chlorine in the short periods because they are not directly followed by a noble gas, whose stable structure they might achieve by gaining or sharing electrons. Instead, these atoms have a strong tendency to form bipositive or terpositive ions by losing two or three electrons, the remaining valence electrons occupying the 3d orbitals, which for these positive ions are more stable than the 4s orbital.

The elements copper, by losing one electron, and zinc, by losing two, can form the ions Cu^+ and Zn^{2+} with a completed M shell of electrons. If the 4s and 4p orbitals were much less stable than the 3d orbitals, instead of about equally stable, this electronic configuration would be similar to the neon configuration; and nickel would be a noble gas, copper an alkali metal and zinc an alkaline-earth metal. The actual, different properties of nickel, copper and zinc result from their power of using the 4s and 4p orbitals in forming chemical bonds. Nevertheless, the effect of the 18-shell configurations (of Cu^+, Ag^+, Au^+) is evident in the normal valences of the elements of subgroups Ib, IIb, IIIb, IVb, which are equal to the group numbers.

These elements may also assume other valences, one or two greater (by losing additional electrons, leaving the 3d subshell incomplete) or two less (by having the 4s orbital occupied by an unshared electron pair).

It is convenient to consider ten of the elements in each long

TABLE V.—*Representing Qualitatively the Relative Stability of Successive Electron Orbitals in Atoms; the Relative Energy Values Change Somewhat With Change in Atomic Number*



period or very long period to be transition elements, corresponding to the introduction of ten electrons in a d subshell. There is some arbitrariness in the selection of these elements, because the sharp differentiation of s, p and d subshells for the outer electrons of an atom in a molecule or crystal is not possible; these subshells are precisely defined only for a system with spherical symmetry; *i.e.*, for a system containing only one nucleus.

Although the selection is arbitrary, it is convenient to consider the elements titanium to gallium inclusive as the first transition elements; zirconium to indium as the second; and hafnium to thallium as the third.

The Lanthanons.—The existence of a long series of very closely related elements, the lanthanons or rare-earth elements, has been clarified by the development of the understanding of the electronic structure of atoms. With increase in the atomic number of the elements the seven 4f orbitals become increasingly stable, until, at lanthanum, 57, or cerium, 58, these orbitals begin to be occupied. In the terpositive gadolinium ion, 64, the 4f subshell is half-filled, with one electron in each of the seven orbitals; and in the lutecium ion, 71, it is completely filled with its complement of 14 electrons.

The lanthanons thus comprise the 14 metals from cerium to lutecium, with the same electronic structure except for the variation from 1 to 14 in the number of 4f electrons. Often lanthanum, with the same electronic structure but with no 4f electrons in the terpositive ion, is also included among the lanthanons, increasing their number to 15.

The 4f orbitals are deep within the atoms—there is a stable noble-gas shell of eight 5s and 5p electrons outside, as well as, in the neutral atoms, two valence electrons in the 6s orbital and perhaps one in a 5d orbital. Because the 4f orbitals are in an inner shell, the properties of the atom or ion are changed only slightly by changes in the number of electrons that occupy them; hence the lanthanons are closely similar to one another in physical and chemical behaviour. This similarity was made strikingly evident by the great difficulty of separating them from the complex mineral mixtures in which they occur in nature, which caused their discovery to be spread over a period of more than a century.

The lanthanons all have +3 as their principal oxidation state, corresponding to the loss of the three valence electrons to more electronegative atoms. Cerium, praseodymium and terbium also occur in oxidation state +4, and samarium, europium and ytterbium in oxidation state +2.

The Actinons.—The only important general question about the periodic system to which the answer remains doubtful concerns the nature of the last period. Because thorium is more closely similar to hafnium than to cerium in many of its properties, and uranium is more closely similar to tungsten than to neodymium, it has been thought that the uranium elements constitute the beginning of a transition period similar to the two long periods, and involving the occupancy of the 6d subshell. However, G. T. Seaborg has pointed out that the properties of the transuranium elements suggest that these elements are members of a second series of the lanthanon type, with occupancy of the 5f orbitals beginning at thorium. It is true that uranium is unlike the lanthanons in that the +6 oxidation state is the most stable of its oxidation states (+6, +5, +4, +3); but neptunium, instead of being similar to rhenium, is reported not to have a stable +7 state; instead, neptunium and plutonium are said to have the same oxidation states as uranium, but with a general shift in stability toward the lower oxidation states.

An answer to this question can be given by the consideration of the stability and nature of the electronic orbitals involved. Although d orbitals contribute to the formation of strong covalent bonds, inner f orbitals are not useful in this way, as is shown by the small tendency of the lanthanons to form covalent compounds. The fact that uranium does form covalent compounds shows that the 6d orbitals are stable enough to be used for this purpose; and the stability of the +6 oxidation state shows that the 5f orbitals of uranium are not sufficiently stable to attract any of the six valence electrons very strongly. Hence the uranium period differs from the immediately preceding period in that the 5f orbitals are less stable relative to the 6d orbitals than are the 4f relative to the 5d orbitals. However, with increase in atomic number the 5f orbitals will increase in stability more rapidly than the 6d orbitals, and ultimately the 5f orbitals will be filled. It is likely that this process has begun at neptunium; and presumably it is completed at element 103, which is similar to lutecium in structure and properties, with probably a greater tendency to the formation of covalent compounds.

The 6d, 7s and 7p subshells are thus successively occupied, with element 118, eka-radon, as the next noble gas, though probably able to form some chemical compounds. The 14 elements from thorium to lawrencium are called the actinons.

Thus this great generalization, the periodic law, which first showed its value through Mendeléyev's prediction of the existence and properties of undiscovered elements, is again being put to the same use, the undiscovered elements of present interest being those that have greater atomic number than the known elements. The undiscovered elements will be sought not in nature's minerals, but in preparations made by man.

PERIODONTAL DISEASES are diseases of the soft tissues around the teeth. Periodontal tissue includes both the (1) gingiva, or gum, the tissue that surrounds the neck of a tooth; and (2) the dental ligament, or attachment membrane, the soft tissue that surrounds the root of a tooth.

The free edge of the gingiva surrounds the neck of a tooth like a collar and slopes away on the outside to become continuous with the oral tissue covering the bony process of the jaw. This outer surface of the gingiva is firm, pink, and slightly stippled (rough). As the healthy gingiva completely surrounds the neck of a tooth, a shallow sulcus, or crevice, lies between the border of the gingiva and the line of attachment to the tooth surface. The remaining inner surface of the gingiva is normally attached to the roots of the teeth and is continuous with the deeper periodontal tissue. (*See* also TEETH: *Human Dental Anatomy*.)

The health of the gingiva is largely dependent upon the practice of regular daily hygienic care by proper tooth brushing and the use of dentifrices and mouth rinses. A surface covering of epithelium protects the soft tissue from injury and infection. Beneath the epithelium is another tissue, the connective tissue,

which is well supplied with blood vessels. Protective blood cells gather rapidly in the event of injury or infection to heal the soft tissue and resist the infecting agent, but when there is continuous irritation in the gingiva, inflammation results. This brings about the beginning of gingivitis, the simplest and commonest periodontal disease.

Gingivitis.—Gingivitis begins as a mild inflammation that causes bleeding gums. It is seldom painful and therefore frequently overlooked or neglected. It is usually a chronic condition brought about by a low-grade infection in the gums associated with constant mechanical irritation or irritation by dental calculus, food packing between two adjacent teeth, the retention of food, and soft deposits around the gum line. The commonest cause of all is the lack of brushing of the teeth. Inflammation in the gingiva gradually extends into the deeper periodontal tissues, loosening them from their normal attachment to the roots of the teeth. This eventually causes a pocket to form along the root surface beneath the collar of gum tissue, producing the beginning of a periodontal pus pocket, once called a pyorrhea pocket. Vincent's infection, a gingivitis commonly called "trench mouth," is an acute and painful form of gingivitis caused by specific microorganisms. It may be contagious, at least during the most active period of infection.

Hyperplastic gingivitis, or inflammatory enlargement of the gingival tissue, often is associated with certain systemic disturbances, such as diabetes, blood diseases, metal poisoning, and nutritional deficiencies. A more fibrous type of gingival enlargement, known as fibrous gingival hyperplasia, is frequently associated with hormone disturbance during adolescence or pregnancy. Another form of hyperplasia appears as a side effect in the use of diphenylhydantoin sodium in the treatment of epilepsy; this is a very firm, painless, but disfiguring type of fibrous hyperplasia.

All these types of gingivitis are amenable to treatment and can be cured by the removal or correction of the cause. This includes thorough removal of calculus deposits, correction of mechanical irritation, control of infection, and practice of daily home care.

Periodontitis.—Periodontitis, like gingivitis, is a progressive inflammation. It involves the deeper tissues surrounding and attached to the roots of the teeth. As the pocket deepens, the support of the tooth is weakened by loss of surrounding bone. Food residue and bacteria accumulate and stagnate in the pocket. Pus is formed and discharged from the pocket opening into the mouth. Eventually the tooth loosens because of the loss of its bony support. Sometimes an acute infection occurs in a deep periodontal pocket, causing much pain followed by swelling of the surrounding tissue. This is a periodontal abscess. It is not associated with the commoner abscesses that are found at the root tip when there is infection in the root canal.

Periodontitis is curable if treated early. The pockets should be curetted and irrigated, and the roots made smooth. Very often the overlying unattached soft tissue wall of the pocket must be removed surgically to eliminate the pocket. Personal dental hygiene on the part of the patient also is important. (*See* also ORAL SURGERY.)

Gingivosis and Periodontosis.—These degenerative diseases are difficult to explain and to control.

Gingivosis is a rather uncommon and painful condition sometimes found on the labial surface of the gingiva. The surface of the epithelium seems to peel or slough away because of degeneration of the underlying connective tissue, leaving a raw surface. The cause is unknown.

The cause of periodontosis, affecting the deeper periodontal tissues, also is not entirely clear. It seems to have several causes, probably being associated with some systemic disturbance that interferes with nutrition in this local tissue, causing it to break down. Periodontosis is characterized by drifting or separating teeth and by the sudden formation of pockets of considerable depth. There are seldom any calculus deposits on the affected teeth or any bleeding until a late stage of development. Injury from the occluding forces as the teeth are brought together results in destruction of the supporting bone and loosening of the teeth.

Tissues that are continuously subjected to severe stress may be affected by certain systemic factors that reduce the ability of the tissues to function and to repair the damage of daily wear and tear. The gums may appear healthy even though deeper tissue along the root surfaces is degenerating. It is thought that some internal disturbance interferes with the nutrition and function of the cells in the supporting tissue of the teeth. Some diseases interfere with metabolism and lower the ability of the blood to nourish the tissues properly. Inherited tendencies may affect the quality of constantly developing new bone and muscle tissue. Teeth with weakened support cannot take part in normal occlusion. When the teeth begin to separate and drift away from their normal position it becomes evident that the supporting tissue is affected and the early symptoms of periodontosis are appearing. The onset of periodontosis cannot be predicted, and no one can foretell which teeth will become involved in a susceptible person. The condition most commonly occurs in the third or fourth decade of life, but systemic diseases may bring about an earlier or later appearance. If inflammation develops in the gingivae and the deeper tissues, the progress of both the inflammatory and degenerative forms of disease is greatly accelerated. Deep pockets form along the surfaces of the roots and discharge pus into the mouth, and there is great loss of bony support of the affected teeth.

The anterior teeth often separate and protrude, while the posterior teeth move from their normal positions and are brought into abnormal relation with posterior teeth of the opposing jaw. This often subjects those teeth to abnormal biting stress and hastens their loss because of injury to the surrounding periodontal tissues. In the later stages of periodontosis, both the degenerative and the inflammatory symptoms become combined in a condition known as periodontitis complex.

In its early stages periodontosis can be alleviated and often cured by correcting an unbalanced diet and instituting very thorough home care of the teeth and gums. When the teeth begin to drift, retaining appliances are installed. Surgical removal of pockets is essential to remove diseased tissue and restore healthy underlying bone upon which new soft tissue can grow.

Traumatism.—The teeth normally are held firmly within a bony socket surrounded by very dense and strong tissue fibres of the periodontal attachment, or ligament. Although the teeth may seem immovable, there is a slight movement when pressure is applied horizontally. Normal periodontal attachment tissue varies in thickness from 0.1 to 0.3 mm.; if the root of a tooth moves more than half that distance under pressure, the periodontal tissue will be crushed against the bony socket.

When the teeth are brought into occlusion the cusps of the teeth of one jaw should fit into the grooves of the teeth in the opposing jaw in cusp-to-groove contact. Many factors interfere with this ideal arrangement, causing malocclusion, which results in abnormal horizontal stress upon some tooth or teeth. Constant horizontal stress may force a tooth to move and eventually loosen it in its socket. The effect of this causes traumatic injury in the supporting tissue. This has been known as traumatic occlusion but is more correctly called traumatism.

Periodontal Atrophy.—Atrophy is a wasting away or shrinking of tissue. Periodontal atrophy is classed as a degenerative condition, although it is not classed as a disease. Receding gums with a healthy colour and a normal attachment to the crown or root of a tooth are evidence of shrinkage and not of disease. When teeth have no occluding contact or function, the attachment tissue on the root surface undergoes a degenerative change, just as does almost any other unused muscle or organ. This is called disuse atrophy. Another form of atrophy, occurring late in life, is called senile atrophy. Atrophic changes in the gingival tissue may occur at any time after middle life. Brushing the teeth crosswise may cause toothbrush trauma to the gingiva and early recession of the gingival border of the gums, although it does not result in periodontal disease. (ER. D. C.)

Bruxism.—Bruxism is a voluntary or involuntary nonfunctional movement of the lower jaw. It is expressed as either occasional or habitual grinding, clenching, or clicking of the teeth at any time of day or night. Many individuals who have this habit

are unaware of it. Although the major cause of bruxism is psychological, there may be local, systemic, and occupational factors. In children, the cause may be of a developmental nature. Acts of bruxism vary in type, frequency, duration, intensity, and direction of force. Though not always destructive, the major effects are primarily wear of the teeth and loss of the bone structure that supports the teeth. Traumatism and disturbances in the joints of the jaw may develop. Bruxism should be suspected in all cases of periodontal disease. (S. C. Na.)

PERIOECI (Greek Perioikoi, "dwellers around") had a specialized meaning in several ancient states, notably in Laconia, where it designated the free but voteless inhabitants ruled over by the Spartan aristocracy. Their origin is disputed, some ancient writers maintaining that they were the older Achaean inhabitants conquered by the invading Spartans, others that, like the Spartans themselves, they were Dorians. They lived in numerous cities of varying size, with a large measure of local independence but excluded from Spartan citizenship and subject to the supervision of the ephors and probably also of governors called harmosts. Sparta depended heavily on their military service: at Plataea in 479 B.C. an equal number of Spartans and *perioeci* fought in separate units; by the Peloponnesian War they fought together, and at Leuctra in 371 the army consisted mainly of *perioeci* with a Spartan cadre. Trade and industry, forbidden to Spartan citizens, were open to them. They were generally content with their status, and after 370 only the northern frontier areas, Arcadian by race, fell away from Sparta. In the Roman period the *perioeci* mostly formed separate states.

In Crete, on the other hand, this name was used for the serfs who tilled the land round each separate city. Elsewhere the political meaning, if any, depends on the circumstances, but the literal geographical sense is always important. (A. As.)

PERIPATETICS, the name given in antiquity to members of the school of Aristotle and their successors. The name was derived from the Peripatos, a covered walk in the Lyceum in Athens, where Aristotle began to teach in the year 335 B.C., on his return from Macedonia. Previously, he had attended the school of Plato in the Academy (up to Plato's death in 348–347 B.C.); it was in the Peripatos that he completed his transformation of the Platonic teaching, abandoning the doctrine of transcendent ideas and adopting in its place an empirical attitude to reality as manifested in nature and in history. This led to the most comprehensive encyclopaedic system of thought that was ever known in antiquity. (*See* Aristotle.)

Aristotle's immediate successor as leader of the school was Theophrastus (*q.v.*). Neither he nor Eudemos of Rhodes (*q.v.*) made any radical change in the teaching; they concentrated rather on the development of individual aspects. Theophrastus, however, tried to strengthen the systematic unity of the whole, giving further development to nearly every part of Aristotle's doctrines. But the increasing decline of the metaphysical elements, together with the expansion of empirical methods, was preparing the way for the coming independence of the specialized subjects. Soon the Peripatos could hardly any longer be called a school of philosophy, since it had lost even its unity of ethical teaching and was disintegrating into a number of separate disciplines. Dicaearchus and Aristoxenus (*qq.v.*), abandoning the cardinal principle of Aristotelian metaphysics, renounced belief in the immortality of the soul. Furthermore, Dicaearghus ceased to subscribe to the contemplative ideal of life preached by Theophrastus; and Aristoxenus confronted the ethics of Plato and Aristotle with a so-called Pythagorean theory reconstructed from traditional sources.

Further proof of how soon the school lost its philosophical unity is supplied by Clearchus of Soli who, like Aristoxenus and Dicaearchus, may still have been a personal disciple of Aristotle. In opposition to the other two, he clung to the idea of the soul's immortality. However, he attempted to prove this not through the dialectic methods of Plato and Aristotle but by means of popular tales about states of ecstasy, which he tried to link to primitive shamanistic traditions. In his treatment of ethical questions Clearchus seems to adhere to a general ideal of "moderation" which was not bound to any particular philosophical premisses. Thus in his treatise *Peri Bion*, in which he explains his attitude toward hedonism, the Aristotelian idea of the coexistence of several equally justified ways of life seems to have been forgotten.

A characteristic of this disintegration is the increasing number of specialized treatises on the natural sciences. Some such treatises written by Theophrastus are extant, and we know at least the titles of certain monographs on zoology, on physiology and on medicine by Strato of Lampsacus and by Clearchus. Strato moreover, in his physics, separated himself entirely from the teleological principles of Aristotle, approaching more nearly to the atomic theories of Democritus. According to the scientific qualifications of each investigator, this specialization in the sciences proved to be sometimes an advantage and sometimes a drawback: thus some Peripatetics contributed to the development of empirical disciplines of considerable stature, while others produced a number of works on the miraculous intended only for entertainment.

The achievements of the Peripatos are equally uneven in the field of the humanities. The foundation had been laid by Aristotle, who gathered material for his teaching on statecraft from political history, studied the philosophy of his predecessors as a basis for his own theories and discovered in ancient poetry important and vital examples for his own ethics. Here again the various branches became increasingly independent as time went on. Thus Demetrius Phalereus, who ruled as Macedonian governor in Athens from 317 to 307 B.C., wrote on Athenian constitutional history as well as on his own political activities. In their commentaries on the poets, the Peripatetics were able to refer back to old traditions that had begun with the explanations of Homer by the Rhapsodists; and their biographies of the poets were based on popular books on the life of Homer or Hesiod, from which they often borrowed the fictional embellishments. Aristotle, Dicaearchus, Demetrius Phalereus and Chamaeleon (a representative of the first generation of disciples) are all attested to have written works on Homer; and lyric and dramatic authors were equally favourite subjects for dissertations. The Peripatos notably stimulated the Alexandrian grammarians from Zenodotus to Aristarchus, whose editions and interpretations of the classical texts preserved that literature for posterity.

A new period in the history of the Peripatetics began in the 1st century B.C., when Andronicus of Rhodes (*q.v.*) published the long-neglected works of Aristotle and thus aroused interest in the philosophical tradition proper to the school. With Andronicus there came into being a way of interpreting the main writings of Aristotle which was to last as long as the Roman empire, reaching its climax with Alexander of Aphrodisias (*q.v.*). Admittedly Alexander interpreted Aristotle in a nominalist sense, maintaining that the universal was a mere abstraction from the particular (whereas Aristotle had in fact given it ontological priority, though conceding that our knowledge may spring from the particular). Alexander's interpretation, as Strato's long before him, involved opposition to Platonism at a time when other exponents were attempting on the contrary to smooth out as far as possible the differences between the teachings of Plato and the teachings of Aristotle.

As a synthesis of the two philosophies was actually brought about soon after Alexander's time by Plotinus, Aristotelian thought came to exert an influence in Neoplatonism (*q.v.*). This survived long after the school of the Peripatetics had perished. (F. Wi.)

PERIPATUS, a genus of remarkable wormlike Arthropoda (*q.v.*) belonging to the class Onychophora. The name is often loosely applied to all members of this class, which at one time were believed to be intermediate between Annelida (segmented worms) and Arthropoda (insects, spiders, crabs).

See Onychophora.

PERISCOPE, an optical instrument used in land and sea warfare and submarine navigation to enable an observer to see his surroundings while remaining under cover, behind armour or submerged. Technicians engaged in nuclear research employ extremely long periscopes to observe the functioning of nuclear reactors from a safe distance.

A periscope always includes, among its optical elements, two mirrors or reflecting prisms to change the direction of the light coming from the scene being observed: the first reflects it down through a vertical tube and the second diverts it horizontally so that it can be viewed conveniently. There is usually a telescopic optical system, which may be very complex, which gives magnification, provides as wide an arc of vision as possible and includes a crossline or a reticle pattern which establishes the line of sight to the target. There may also be devices or accessories for estimating the range and course of the target, and for photographing through the periscope.

The simplest type of periscope consists of a tube at whose ends are two mirrors which are parallel to each other but at 45° to the axis of the tube. This device produces no magnification and does not give a crossline image for gun-sighting use. The arc of vision is limited by the simple geometry of the tube—the longer or narrower the tube, the smaller the field of view. Periscopes of this type found very wide use in World War II in tanks and other armoured vehicles, as observation devices for the driver, gunner and commander. When fitted with a small auxiliary gunsight telescope at the side of the tube, the tank periscope can also be used in pointing and firing the guns. By employing tubes of rectangular cross section, approximately 7 in. by 2 in., wide horizontal fields of view can be obtained—large vertical fields are not necessary in surface combat. The vertical displacement of the line of sight is of the order of one foot. Sometimes solid prisms of glass or plastic are used in place of the end assemblies consisting of a mirror and two sealing windows. The periscopes and their swivel mounts are designed and constructed so as to be as water- and dust-tight as possible. The top mirror assembly or prism may be detachable, and readily replaceable with a spare unit in case it is shattered by enemy gunfire or is otherwise damaged.

Turret Periscopes.—Periscopes are installed in the gun turrets and armoured conning towers of battleships and cruisers in order that the gunnery officer can sight on the target and, if desired, can bring the guns to bear on it, when the turret is in "local control." The shape and construction of the turret may necessitate a periscope length of as much as 10 ft., for unobstructed vision. A simple instrument of the two-mirror type would have much too narrow an angular field of view; so a telescopic optical system is always employed. This may be thought of as having the effect of placing the observer's eye much closer to the top end of the periscope, thereby greatly increasing his arc of vision. It also makes possible magnification, which is necessary because the guns fire at long ranges. A crossline reticle can easily be included for gun-sighting use.

A typical optical system for such a periscope is shown schematically in fig. 1, in which the outline of the instrument is indicated also, for reference. The function of each optical part, described in order, is as follows: the upper sealing window *A*, through which light enters from the target scene; the head mirror or prism *B*, which reflects the incoming light down the periscope tube; the objective lens *C*, a cemented achromatic doublet lens which brings the light to a focus; a plano-convex collective lens *D*, located at this focus, and upon which the crossline or other reticle pattern may be etched; a pair of similar achromatic doublet lenses *E* and *F* which erect the image; the lower deflecting prism *G*, which turns the light into a horizontal path; the sealing plate *H*, at the lower end of the main periscope tube; one or more colour filters *I*, for haze and glare reduction, usually interchangeable red, yellow, polarizing and clear plates; the eyepiece, which consists of two doublet lenses, a so-called field lens *K* and an eye lens *L*. If it is desired to be able to illuminate the reticle for night use, the crossline may be etched on the lower sealing plate *H* rather than on the collective lens *D*. The sealing plate must then be located at the second focal point, *J*. The reticle markings may include several short vertical lines equally spaced on each side of the vertical crossline; these are used in estimating the deflection error of the projectiles. Moving parts outside the sealed main portion of the periscope are the interchangeable colour filters and the eyepiece which can be adjusted in focus to suit the individual observer.

This optical system can be thought of as consisting of two astronomical telescopes. The upper one is made up of lenses *C*, *D* and *E*. It provides little magnification but transfers the target image and field of view down the periscope tube to lens *F*, which is the objective lens of the second telescope; *K* and *L* constitute its eyepiece. This second astronomical telescope magnifies the image in the ratio of the focal lengths of the objective and eyepiece. It also erects the image, which has been inverted in both the up-and-down and left-to-right senses by the first telescope.

The mirror or reflecting prism at the upper end of the periscope tube is so arranged that it can be tilted by means of a mechanism that is actuated by a handwheel located near the eyepiece; the line of sight may thus be carried through as much as 30° above and below the horizontal. The entire periscope can be rotated in its mount about its vertical axis through 360°, so as to scan the horizon. In order to prevent fogging of optical surfaces and the consequent loss of vision, the interior of the periscope must be thoroughly dried, filled with dry air or nitrogen and sealed tightly against the atmosphere. Gas inlet and outlet valves are ordinarily provided for this purpose.

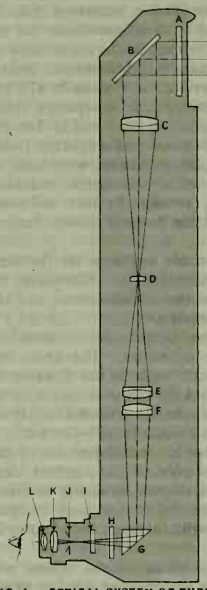

FIG. 1.—OPTICAL SYSTEM OF TURRET PERISCOPE USED IN WARSHIPS (*see* TEXT)

A typical turret periscope will have an optical magnification of approximately 10 and an angular field of view of 4° to 6°. The brilliance of the image seen by the observer depends on the over-all light transmission of the instrument and on the size of the exit pupil; *i.e.*, the beam of light that emerges from the eye lens. Conditions imposed on the optical design usually permit a fairly large exit pupil, say 5 mm. in diameter, which is sufficient for day use. For night use, however, the emergent beam of light should entirely fill the pupil of the observer's eye for maximum brightness of image. This necessitates an exit pupil of 7- to 8-mm. diameter, which usually entails larger diameter optical elements throughout, with a concomitant increase in over-all size, weight and cost of the instrument. The percentage of light transmitted by an optical instrument can be greatly increased by coating all air-to-glass surfaces of the various lenses and prisms with so-called reflection-reducing films. The use of such films in the optical system of fig. 1 will increase its light transmission from around 30% to more than 50%, a gain of almost 100%. Also, the image rendition is improved in that crisper, clearer images are obtained and ghost images and flare spots are eliminated. This technique of coating optical surfaces came into wide use in military optical instruments during World War II.

Submarine Periscopes.—Periscopes used in submarines are similar in principle to the turret periscopes of warships but differ from them in certain important respects because of the following special conditions which are imposed: the submarine periscope must be much longer, and the top few feet of its length must be greatly reduced in diameter. The periscope must be capable of being raised and lowered into the hull of the submarine; it should

have available both low and high optical magnifications.

The over-all length of a periscope may exceed 40 ft., and a large fraction of this length will be exposed, outside the hull of the submarine, at maximum extension of the periscope. Great forces are exerted on the tube in dragging it through the water when the submarine is underway submerged. Thus, the tube must be large enough to give sufficient rigidity without offering too much resistance to motion through the water; a diameter of from 6 to 8 in. is usually selected, depending on the length. This tube must be made of a corrosion-resistant material and must be very carefully machined for perfect roundness, straightness and uniformity in diameter, since it must permit both rotation about its vertical axis and raising and lowering of the periscope in the long watertight gland through which it enters the hull of the submarine. Near the upper end of the periscope tube is a tapered portion above which is a narrow tube 2 or 3 ft. in length, surmounted by a slightly larger head which contains the entrance window and the elevating prism.

The diameter of this tube is made as small as possible, often less than 2 in., to reduce the probability of its detection by enemy observation and to cut down the size of the wake or "feather" caused when the submerged submarine is in motion with its periscope elevated into observing position.

All of the joints in the periscope tube, the sealing of the upper window and the packing of the stuffing box at the hull line must be made tight enough to withstand the considerable hydrostatic pressures encountered when the submarine submerges. Rotation of the periscope is usually accomplished by the observer, who grasps two folding handles at the lower end; proper adjustment of the stuffing box permits this rotation without allowing sea water to leak into the submarine.

The periscope is raised, or is lowered into a well extending into the hull of the boat, by push-button-actuated electrical hoisting equipment controlled by the observer.

Two magnifications are usually provided, 1½ and 6. The first gives the observer the impression of normal viewing, the extra power over unity being necessary to overcome the psychological effect of "tunnel vision." The field of view associated with the 1½ power is in the range 32°–40°, depending on other design considerations. Use of the higher power enables the observer to see greater target detail, but restricts the field of view to 8°–10°, one-fourth of the low-power values of angular field, but one-sixteenth the areas.

The magnification change is effected by rotating one of the folding handles at the lower end of the periscope. Rotation of the other handle moves the line of sight through angles between 10° depression below horizontal and 45° elevation, by tilting the head prism. The wide use in World War II of aircraft to hunt down enemy submarines, however, made it necessary to provide "high-angle" or sky-searching periscopes capable of viewing at such elevations as to be able to scan the entire sky, from horizon to zenith.

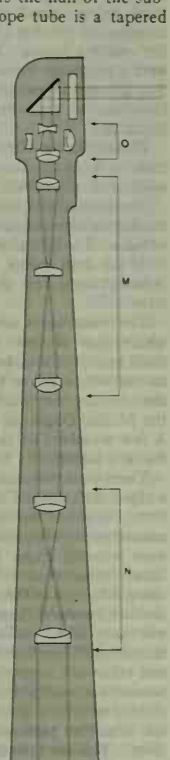

FIG. 2.—UPPER PORTION OF LONG, NARROW-TUBE SUBMARINE PERISCOPE (NOT TO SCALE)

The exit pupil diameter of standard submarine periscopes is 4–5 mm. This is sufficient for day use, but not for the best performance at night, when a value of 7 mm. is needed. In order to obtain this larger light-gathering power, the size of the lenses near the head prism must be increased. Therefore, it is impossible to retain the very small diameter of the upper portion of the periscope tube.

Certain schools of thought maintain, however, that too much emphasis has been placed on, and too high a price paid for, keeping this dimension so small. The light transmission of the most complicated periscopes may be around 15%, which is undesirably low. Treatment of the air-to-glass surfaces of all the lenses and prisms with reflection-reducing films raises the transmission by as much as 200%, according to the number of surfaces involved. The resulting gain in image brightness is very noticeable and is particularly valuable during nighttime, dawn and dusk, the most favourable periods for submarine torpedo attacks.

The reticle lens has engraved upon it special telemeter scales which make possible a rough calculation of the distance of a target vessel, based on an estimate of its length or height. More accurate ranges can be determined by the special stadimeters usually built into or attached to submarine periscopes.

The optical system of a submarine periscope may be essentially that of fig. 1, except that the focal lengths and spacing of the lenses are adjusted to give a magnification of 6. However, for very long periscopes in which the narrowest possible top portion is desired, which severely restricts the diameter of the upper lenses, this optical system will not provide the observer with sufficient field of view. A solution to these difficulties is illustrated in fig. 2. In a location corresponding to above lens *C* of fig. 1 there are added two complete astronomical telescopes, *M* and *N*, each consisting of two or three lenses. The telemeter scales are then engraved on a plano-convex lens in the uppermost astronomical telescope, rather than on lens *D* of fig. 1.

In order to provide the lower magnification of 1½ and still retain a wide field of view and sizable exit pupil, additional lenses must be added at the top end of the complete telescopic system. This is usually done as illustrated in fig. 2, by bringing into the line of sight a small four-power reversed Galilean telescope *O* which consists of two achromatic lenses, the upper of which is diverging and the lower converging. The higher magnification of 6 is obtained when these lenses are swung to the side. The provision of movable lenses and the necessary controls in this already crowded portion of the tube calls for very careful mechanical design. The periscope just described employs the most complicated optical system used in any common military instrument.

PERISSODACTYL, any of the hoofed mammals of the order Perissodactyla, which includes horses, tapirs, rhinoceroses, and their extinct relatives.

GENERAL FEATURES

Structure.—The most characteristic feature of these animals is the structure of the feet. In perissodactyls the axis of the foot passes through the middle toe, whereas in artiodactyls, the other large group of hoofed animals, the axis passes between the third and fourth toes. The outer toes tended to disappear during the evolution of hoofed animals, leaving perissodactyls with an odd number of functional toes (hence the common term odd-toed ungulates) and artiodactyls with an even number (even-toed ungulates). Other features more or less characteristic of perissodactyls are the general tendency for the premolar teeth to resemble molars ("molarization" of the premolars), the presence of a full set of incisor teeth (absent in the upper jaw of most artiodactyls) and the presence of a third trochanter on the femur. The stomach is simple, and there is a large caecum at the juncture of the large and small intestines. All living perissodactyls lack a gall bladder. (*See* ARTIODACTYL.)

Origin and Evolution.—The living perissodactyls are only a remnant of a once-flourishing group that reached the peak of its evolutionary history in Middle Tertiary times, about 30,000,000

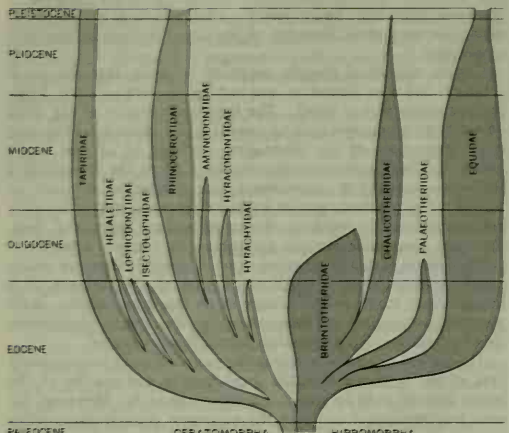

FIG. 1.—EVOLUTION OF THE PERISSODACTYLS. WIDTH OF BAND INDICATES RELATIVE ABUNDANCE OF SPECIES IN EACH BRANCH

years ago, when its members were the dominant hoofed animals in most of the world, occupying about the same position among the animals of that era that deer, antelope, and oxen do today. After the Middle Tertiary they declined rapidly. Most of the families died out completely, and there can be little doubt that the whole order is on the verge of extinction today. The reasons for the decline of the perissodactyls and the rise of the artiodactyls are unknown. At the peak of their development the perissodactyls seem to have been highly evolved and intelligent animals.

The ultimate ancestors of the perissodactyls undoubtedly were among the Condylarthra, a primitive stock of Paleocene mammals that gave rise to most of the later hoofed mammals. The direct ancestors of the perissodactyl stock must have resembled *Hyracotherium*, the ancestral four-toed horse, which lived in the Early Eocene, about 50,000,000 years ago. *Hyracotherium* was primitive in most respects, but its legs were slender and adapted for running. Almost at its beginning the perissodactyl stock divided into two major lines, the Hippomorpha, or horselike perissodactyls, and the Ceratomorpha, or rhinoceroslike perissodactyls. Both lines evolved rapidly, and before the end of the Eocene the perissodactyls had reached the peak of their radiation, with no fewer than 12 families represented. By the end of the Eocene, about 35,000,000 years ago, they had already passed their peak. Only nine families survived into the next epoch, the Oligocene, and four of these died out before the end of the epoch. Only three families are extant today.

SURVEY OF THE ORDER

Hippomorpha

The suborder Hippomorpha is divided into four families: Palaeotheriidae, Equidae, Brontotheriidae, and Chalicotheriidae.

Paleotheres (Palaeotheriidae).—These were the closest relatives of the true horses, and their remains are known only from Europe and Asia. For a time the evolution of the paleotheres in Europe paralleled the evolution of the true horses in North America. Unlike the horse line, the paleothere line was relatively short lived; the last paleotheres died in the Early Oligocene, more than 30,000,000 years ago.

The paleotheres were rather tapirlike browsing animals with low-crowned cheek teeth and short stout legs ending in three toes. The earliest species were small, but some of the later species were as large as rhinoceroses. The best-known genus is *Palaeotherium* (meaning "ancient beast"), which occurs in abundance in gypsum deposits within the city of Paris. These Parisian fossils were studied in detail by the great French anatomist Cuvier in the early 19th century, giving *Palaeotherium* the distinction of being one of the first fossil mammals so studied.

Horses (Equidae).—The fossil record of the horses is the best known of all mammals. It begins in the Early Eocene, about 50,000,000 years ago, with *Hyracotherium*, the eohippus (*q.v.*) or dawn horse. *Hyracotherium*, known from North America and Europe, was very close to the ancestral type of the perissodactyl stock, being a small mammal with a primitive skull, the primitive mammalian number of 44 teeth, and the cheek teeth low crowned for crushing leaves. From this beginning the horse stock underwent a progressive evolution accompanied by a great deal of splitting up into numerous branches, especially during the Miocene. Only one of these branches leads to the modern horses. (*See* EQUIDAE.)

Titanotheres (Brontotheriidae).—The titanotheres or brontotheres left a fossil record nearly as complete as that of the horses, making this one of the best-known groups of fossil mammals.

The titanothere family is remarkable for its short life and for the degree of evolution that took place in this relatively brief period of time. The first titanotheres appeared in the Early Eocene along with the first horses, and the family was completely extinct in North America by the Early Oligocene, about 55,000,000 years later.

The titanotheres were essentially a North American group. The whole span of their history is represented in North American fossil beds; the huge bones of these beasts are particularly abundant in the White River Oligocene beds of South Dakota. Late in their history they pushed into Asia, where the group survived into the Middle Oligocene after all American forms had disappeared. A few members of the titanothere family ranged as far west as Eastern Europe.

There were two main trends in the evolution of the titanotheres: a rapid drift toward large size and a tendency to develop bizarre bony knobs on the nose. In other respects the titanotheres remained relatively primitive throughout their history. The earliest were scarcely larger than a dog, and lightly built, whereas the latest forms were as large as elephants. *Brontotherium* stood about 8 ft. high at the shoulders. The cheek teeth remained square and low crowned throughout all the history of the family. There was only slight molarization of the premolars, suggesting that throughout their history the titanotheres were browsers on leaves and other soft vegetation. In the latest giant species the molars became extremely large, contrasting with the premolars, which remained relatively small. In the first titanotheres the forefeet had the primitive perissodactyl number of four toes, the hind feet three. This toe formula was retained in all the later forms. In the larger and heavier species the skeleton was adapted to supporting great weight: the pelvis flared out; the legs were columnar; and the feet were broad and short. The thoracic vertebrae were char-

acterized by long spines for supporting the weight of the heavy head.

The titanotheres diverged into several lines in the course of their evolution. One line, represented by *Manteoceras*, led to the giant-horned titanotheres. In another line, the dolichorhines (long-headed titanotheres), the skull became very long and horns were never developed. In still another branch, the telmatheres, there were no horns, but the canine teeth became large and tusk-like.

FIG. 3.—LIVING PERISSODACTYLS: (LEFT) HORSE (EQUUS CABALLUS); (CENTRE) SOUTH AMERICAN TAPIRS (TAPIRUS TERRESTRIS); (RIGHT) AFRICAN BLACK RHINOCEROS (DICEROS BICORNIS)

Chalicotheres (Chalicotheriidae).—Compared with the titanotheres, the chalicotheres were a long-lived group; the last chalicothere died in the Pleistocene, only a few thousand years ago. At no time during their long history were they very numerous; they never underwent the spectacular evolution that characterized the titanotheres.

The first chalicotheres were small creatures similar to the other primitive perissodactyls of Eocene times. During the Oligocene and Early Miocene these developed into bizarre animals that have no counterpart among living mammals. The hooves of the earliest chalicotheres evolved into huge claws on both front and hind feet; the body was short; and the front legs were longer than the hind legs so that the animal sloped from front to rear like a giraffe. They were most ungainly looking animals, and it is difficult to imagine what their habits were. The teeth, like those of the titanotheres, were low crowned and square, adapted to crushing soft food. From North America the chalicotheres spread into Eurasia. The best-known chalicothere is the North American *Moropus*, which was the size of a large horse.

Ceratomorpha

The suborder Ceratomorpha is typified by the modern tapirs and rhinoceroses. The group is divided into eight families: the Isectolophidae, Helaletidae, Lophiodontidae, Tapiridae, Hyrachyidae, Hyracodontidae, Amynodontidae, and Rhinocerotidae. Only two of these, the Tapiridae and Rhinocerotidae, have living representatives.

The isectolophids, helaletids, and lophiodonts were early and not very successful side branches of the tapir stock. Nearly all died out before the end of the Eocene. They were mostly small slender creatures, generally similar to the other primitive perissodactyls, although *Lophiodon* of the Late Eocene of Europe was as large and heavy as a rhinoceros.

Tapirs (Tapiridae).—In many ways the living tapirs are primitive perissodactyls, very similar to the common ancestors of all perissodactyls. This is in part because they have retained the habits of the early perissodactyls: they live in forests and still browse on leaves and soft vegetation instead of grazing on harsh grasses. The back is curved instead of being straight as in fast-running perissodactyls. The cheek teeth are low crowned, have a simple pattern, and lack a cement covering. The last three premolars are strongly molarized, as in the horses. The only striking specialization of the tapirs is the development of a short flexible proboscis. (*See* also TAPIR.)

True tapirs first appeared in the Oligocene, probably as descendants of one of the more primitive Eocene groups; some students think they may have descended from the helaletid *Heptodon*. The earliest known true tapir is *Protapirus*, found in North America and Europe. *Protapirus* was similar to modern tapirs, even having a tapirlike proboscis, and the further evolution of the group involved mostly an increase in size. Fossil tapirs are relatively rare, as is true of all forest-dwelling animals.

Rhinoceroses (Rhinocerotidae).—The rhinoceroses and their relatives (hyrachyids, hyracodonts, and amynodonts) have the most complicated history of any group of the perissodactyls. The living rhinoceroses are the only survivors of this large assemblage, and several species of these are on the verge of extinction. There can be no doubt that this group of perissodactyls, once numerous and successful, is about to disappear forever. (*See* also RHINOCEROS.)

The earliest known rhinocerotoid is *Hyrachyus*, a small slender creature the size of a large dog, rather similar to the earliest horses in appearance. *Hyrachyus* lived in North America in Eocene times. In the Late Eocene the hyrachyid stock gave rise to two lines that continued the further evolution of the rhinocerotoids. One of these lines was the hyracodonts or "running rhinoceroses," typified by *Hyracodon* of the North American Oligocene. These were long-necked, slender-legged animals, with three toes in front and three behind. None of them had horns. They probably paralleled the early horses in their habits, and may in fact have competed with them. The running-rhinoceros line died out at the end of the Oligocene. A second branch of the hyrachyid stock was the amynodonts, represented by *Amynodon* and *Metamynodon*. The amynodonts were heavy-bodied, short-legged animals about the size and build of a hippopotamus. They had no horns, but the canine teeth were large and daggerlike. The premolar teeth never became molariform. Their bones are usually found in river-channel deposits, and it is likely that their habits were similar to those of the river-loving modern hippopotamus.

The known history of the true rhinoceroses begins in the Oligocene, but these earliest-known forms were probably derived from the running-rhinoceros stock at some time during the Eocene. The rhinoceroses, in contrast to the running rhinoceroses, tended toward large size very early in their history. The premolar teeth rapidly became molarized, as in the horses, but the incisors formed a special chisellike cropping tool. Some, but not all, of the later species developed horns on the nose; these are not true horns, however, being composed entirely of matted hairs. Although the true rhinoceroses seem to have originated in North America, most of their evolution took place in the Old World.

One of the early true rhinoceroses was *Caenopus* from the Oligocene of North America, a heavy-bodied hornless creature standing about 5 ft. high at the shoulders. From this and other early species the rhinoceroses radiated into several phyletic lines during the Oligocene and Miocene. Thus *Teleoceras* and its relatives were remarkably short-legged animals, apparently with amphibious habits similar to those of the modern hippopotamus. The elasmotheres were giant rhinoceroses, with a large horn on the forehead instead of on the nose, that lived in Eurasia in the Pleistocene. The Asiatic baluchitheres were the largest of the rhinoceroses, and *Baluchitherium* itself was the largest land mammal that ever lived. It stood about 18 ft. high at the shoulders, had a head about 4 ft. long, and was hornless.

The direct ancestors of the modern rhinoceroses appeared in the Late Miocene. The modern species belong to several different groups with slightly different ancestries. The one-horned Indian rhinoceros (*Rhinoceros*) most closely resembles the ancestral form. The two-horned Sumatran rhinoceros (*Ceratorhinus*) is apparently related to the woolly rhinoceros depicted in the cave paintings of Stone Age man. The two-horned rhinoceroses of Africa, the black (*Diceros*) and white (*Ceratotherium*), represent a separate branch.

CLASSIFICATION AND DISTRIBUTION

The following classification is one of several taxonomic outlines. An asterisk (*) indicates an extinct group.

Suborder Hippomorpha
- Superfamily Equoidea
  - Family Palaeotheriidae* (Eocene: Asia; Eocene-Oligocene: Europe).
  - Family Equidae—horses (Eocene-Pleistocene: North America; Eocene-Recent: Europe; Miocene-Recent: Asia; Pliocene-Recent: Africa; Pleistocene: South America; worldwide in domestication).
- Superfamily Brontotherioidea*
  - Family Brontotheriidae* (Eocene-Oligocene: North America, Asia, Europe).
- Superfamily Chalicotherioidea*
  - Family Chalicotheriidae* (Eocene-Miocene: North America; Eocene-Pliocene: Europe; Eocene-Pleistocene: Asia).

Suborder Ceratomorpha
- Superfamily Tapiroidea
  - Family Isectolophidae* (Eocene: North America, Asia).
  - Family Helaletidae* (Eocene-Oligocene: North America, Asia).
  - Family Lophiodontidae* (Eocene: Europe, Asia).
  - Family Tapiridae—tapirs (Eocene-Pleistocene: North America; Oligocene-Pleistocene: Europe; Miocene-Recent: Asia; Pleistocene-Recent: South America).
- Superfamily Rhinocerotoidea
  - Family Hyrachyidae* (Eocene: North America, Asia).
  - Family Hyracodontidae* (Eocene: Asia; Eocene-Oligocene: North America).
  - Family Amynodontidae* (Eocene-Oligocene: North America; Eocene-Miocene: Asia; Oligocene: Europe).
  - Family Rhinocerotidae—rhinoceroses (Eocene-Pliocene: North America; Eocene-Pleistocene: Europe; Eocene-Recent: Asia; Miocene-Recent: Africa).

(D. D. D.)

PERITONITIS, is an acute or chronic, localized or generalized inflammation of the peritoneum. Before the development of aseptic surgery in the latter half of the 19th century, almost all patients who underwent abdominal surgery developed peritonitis and died; consequently, such surgery was seldom attempted. Even with the improvements brought about by aseptic surgery, about 33% of all peritonitis cases terminated in death, although a much greater amount of abdominal surgery was attempted. With the advent of sulfonamides, antibiotics, and improved surgical and therapeutic techniques in the 1940s, the peritonitis mortality rate dropped to between 5% and 10%, and early in the second half of the 20th century, the incidence of peritonitis in abdominal surgery was only about 2%. Infection following surgery was, however, no longer the main cause of peritonitis.

Acute peritonitis commonly arises as a result of extension of infection from an appendix that has been permitted to become gangrenous in appendicitis and to perforate, discharging infected fecal material into the abdominal cavity. It may also follow the perforation of a gastric or duodenal ulcer; the bursting of abscesses or cysts into the abdominal cavity; or the extension of gonorrheal infection of the uterus in the female. It may arise as a complication of abdominal surgery, usually when a leak develops after the intestines are sutured together following the removal of a segment for cancer or some other disease. The escape of bile from the gallbladder or a bile duct into the peritoneal cavity may produce a rapidly fatal acute peritonitis.

At onset of the inflammation, the peritoneum loses its shiny appearance, becoming rough, granular, and markedly congested. An exudate begins to flow into the peritoneal cavity; it is at first thin and turbid, later becoming thick and purulent with increasing amounts of fibrin. The intestines become glued together and adherent to the omentum, abdominal wall, and other abdominal organs. The inflammation of the peritoneum is usually due to the aerobic and anaerobic bacteria commonly present in the intestinal tract, which overcome the resistance of the peritoneum when constantly replenished, as from a leak in the bowel, or from infected foreign material such as food or a bit of necrotic appendix.

Acute peritonitis usually begins with a chill, vomiting, and pain in the abdomen with extreme tenderness so that pressure, even of the bedclothes, cannot be borne. The patient lies on his back with the knees drawn up to relax the abdominal muscles; the breathing becomes rapid and shallow and is performed by movements of the chest only, the abdominal muscles remaining quiescent, which is not the case in healthy respiration. The abdomen becomes swollen as a result of gaseous distention of the intestines, and there is usually constipation. The pulse is rapid and feeble, and the temperature rises to 104° or 105° F (40° or 40.56° C). There is a complete absence of intestinal peristalsis. A cold, clammy sweat appears on the forehead, and the eyes are withdrawn into the orbits. The expression is one of great anxiety, but the mind remains clear even when death approaches.

Death results from the cessation of movements in the intestinal tract so that gastric and duodenal secretions accumulate in the stomach and are lost to the body as a result of vomiting. The continued escape of the digestive secretions produces a progressive demineralization, dehydration, and alteration in the chemical composition of the blood. The secretion of urine decreases and finally stops. When these disadvantageous factors are combated by decompression of the stomach and intestines by suction tubes and intravenous administration of salt solution, many patients make a remarkable recovery. It is probable that paralysis of the intestines, secondary to the infection of the peritoneal cavity, is more important as the cause of death in generalized peritonitis than is invasion of the bloodstream by bacteria or the absorption of poisonous materials from the peritoneal cavity.

The treatment of generalized peritonitis consists in the administration, systemically, of drugs such as penicillin, streptomycin, chlortetracycline (Aureomycin), or sulfadiazine; and a surgical operation designed (1) to remove from the peritoneal cavity foreign material that serves as a nidus, or focus of infection, (2) to close perforations of the intestinal tract, and (3) to provide drainage. Decompression of the intestinal tract by tubes introduced through the nose into the stomach, with constant suction, is of great value. Blood transfusions and intravenous administration of physiological solutions of sodium chloride and other salts are very helpful.

(L. R. Dt.)

PERIWINKLE, in zoology, any small marine snail belonging to the family Littorinidae. They are widely distributed shore (littoral) snails, chiefly herbivorous, usually found on rocks, stones or pilings between high and low tide marks; a few are found on mud flats and some tropical forms are found on the prop roots of mangrove trees. Of the approximately 80 species in the world, ten are known from the western Atlantic. The common periwinkle, *Littorina littorea*, may be found in great abundance on the rocky shores of northern Europe and northeastern North America. It is the largest, most common and widespread of the northern species. It may reach a length of 1½ in., is usually dark gray and has a solid spiral (turbinate) shell that readily withstands the buffeting of waves.

Formerly, periwinkles were an important source of food, particularly for the poorer classes in the British Isles, France and the Netherlands. In 1858 the London market consumed 76,000 bu. Since that time periwinkles have been considered a delicacy by many people and are still consumed in large quantities. In Europe they are frequently sold by street vendors, particularly in seaside towns. In France, where they are known as *vignot* or *vignette*, the snails are usually boiled in a small amount of heavily salted water (the salt tends to loosen the animal from the shell). The meat is then either made into periwinkle soup or served with butter or a variety of sauces.

The breeding habits of periwinkles are quite variable. *Littorina saxatilis*, which lives high up on rocks and is often out of water for long periods of time, holds its eggs in a brood sac until the young are fully developed, at which time they emerge as tiny crawling replicas of the adult.

The common periwinkle was introduced into North America at Halifax, Nova Scotia about 1857 and has spread as far south as New Jersey. It is very common on the rocky shores of New England, and also occurs on shallow muddy bottoms, along the banks of tidal estuaries and among the roots and blades of marsh grass

where the water is only moderately salty.

All species in the Littorinidae are important as a favourite food of many shore birds, particularly ducks.

In many sections of the southern United States the term periwinkle or penny-winkle is applied to any small fresh-water snail.

See also MOLLUSK; SNAIL; SHELLS AND SHELL COLLECTING.

See J. C. Bequaert, "The Genus *Littorina* in the Western Atlantic," *Johnsonia* 1, no. 7, pp. 1–27, pl. 1–7 (1943); C. M. Yonge, *The Sea Shore* (1949). (R. D. T.)

PERIWINKLE, in botany, the name given to various plants of the genus *Vinca*, of the dogbane family (Apocynaceae). The name periwinkle is possibly taken from *pervinka*, the Russian name of the flower, which in turn is derived from *pervi*, "first," as it is one of the first flowers of spring. The lesser periwinkle (*V. minor*), with lilac-blue flowers, ¾ in. across, an evergreen, trailing perennial, has run wild throughout eastern North America. It is native to Europe and is found in the British Isles. The similar greater periwinkle (*V. major*), with purplish-blue flowers, 1 to 2 in. across, native to continental Europe, has become naturalized in England. The Madagascar periwinkle (*V. rosea*) is of world-wide distribution in the tropics.

PERIYAR, a river and lake of southern India. The river rises in the Cardamom Hills and flows westward for about 140 mi. through the state of Kerala into the Arabian Sea. Its source is in a wet part of the country with a long rainy season, and it flows across well-watered terrain where no irrigation is required. The upper valley was accordingly dammed, and from the large irregular-shaped Periyar Lake thus formed the water was taken by a tunnel for more than one mile through the mountains to the dry eastern side in the state of Madras. There the water from the lake irrigates a large area in the vicinity of Madurai. This has been a successful operation since 1895, and one of the later projects of independent India was the development of hydroelectric power from the lake. The Periyar hydroelectric scheme, with a planned output of 105,000 kw., was commissioned in 1958. (L. D. S.)

PERJURY, in a general sense and by etymologic origin, means lying under oath. The common definition of perjury as a criminal offense is an intentional misstatement of material fact made under oath or affirmation in a legal proceeding before a tribunal authorized to conduct the proceeding. Related offenses under modern penal codes deal with "false swearing" under other circumstances, and with non-sworn falsification in official matters.

As a transgression of spiritual significance, it was formerly in England subject only to religious sanctions administered by ecclesiastical authorities. In the 17th century in England the Court of Star Chamber began to punish the giving of false sworn testimony as a secular offense akin to obstruction of justice. Anglo-American legislation thereafter defined and expanded the offense of falsification in official matters. It was broadened to include false sworn testimony not only before judges but also in legislative and adminlstrative hearings. Either by further enlargement of perjury, or by special enactments on "false swearing," falsification of affidavits was made punishable. Penal sanctions were extended to falsification on "affirmation" as well as oath, so that the statutes would apply to those unwilling to be sworn. In the 20th century, criminal law in this area, departing entirely from the oath concept, expanded in a variety of statutes penalizing any written or even oral, misrepresentation in official inquiries or proceedings.

A classic requirement of the law of perjury is that the falsification be "material." With few exceptions, the legislatures and the courts have refused to treat trivial or irrelevant lies as felonies. Usually it is said that anything "capable of influencing the tribunal on the issue before it" is material. But the scope of perjury has sometimes been restricted by stringent and arbitrary interpretations. Thus a New York case held that it was not perjury falsely to testify in a divorce suit that the husband had committed adultery with X on one occasion, when the divorce complaint charged only the commission of an adulterous act with X on another occasion, since only the latter was material in the suit (*People* v. *Teal*, 196 N.Y. 372, 89 N.E. 1086 [1909]). In reaction against such decisions, some codes have eliminated materiality as an element of the offense. Examples of this approach are seen in the *Indian Penal Code*, par. 193; *Canadian Criminal Code*, par. 99(a) and 112; and the *Model Perjury Act* recommended by the commissioners on uniform state laws in 1952. More commonly, the materiality requirement has been retained for felonious perjury but eliminated for "false swearing," a statutory misdemeanour. The American Law Institute approved this solution in 1957.

To establish perjury the prosecution must prove that the statement was false and known to be so. Furthermore, it is commonly provided that the testimony of a single uncorroborated witness shall not suffice to prove falsity. On the other hand, it has been held that a person may be convicted of perjury regardless of the objective truth of the statement made, if, true or false, he did not believe it. In such case, it is said, he falsely represented his own belief.

A special problem of some importance in the law of perjury is whether a person commits the offense by lying under oath in a criminal or other proceeding directed against him. Under some legal systems, of or derived from continental Europe, defendants and other litigants are not sworn or the perjury statute has a restricted application to them. It is thought to be unfair or unrealistic to impose penal sanctions on a witness who is so obviously under pressure to give an account favourable to himself. On the same principle, in a minority of English-speaking jurisdictions, including England and the state of Georgia, the defendant in a criminal case may make an unsworn statement. Generally, however, U.S. law makes no such distinctions in favour of defendants, who, if they choose to testify, may be prosecuted for perjury. In consequence, there have been cases where a person has been tried for crime, acquitted and subsequently convicted of perjury based upon his sworn denials of guilt in the earlier trial; an example is *State* v. *Leonard*, 236 N.C. 126, 72 S.E. 2d 1 (1952). In a contrasting case, *United States* v. *Williams*, 341 U.S. 58 (1951), the defendant was convicted of perjury for false self-exculpating testimony in a prior trial in which, nonetheless, he was convicted of the crime charged.

The opportunity to question a supposed culprit under oath as to alleged misconduct in the remote past has also been used to secure from him sworn denials which can then be prosecuted as perjury, notwithstanding that prosecution for the original offense would be barred by the statute of limitations. It has been argued that this violates the spirit of limitations provisions, which are intended to prevent prosecution where lapse of time, death of witnesses and dimming of recollection make it difficult to determine the truth. (*See* comment on the prosecution of Alger Hiss, 40 *J. Crim. Law* 344 [1949]; Note, 102 *U. Pa. Law Rev.* 630, 649 [1954]).

The outer limits of the area in which the criminal law may be usefully or safely employed to repress lying are reached when legislatures undertake to penalize unsworn oral misrepresentation to any sort of official; *e.g.*, a policeman or an individual legislator making informal inquiries. In *King* v. *Manley* (1933), 1 K.B. 529, the English court of criminal appeal affirmed conviction of a woman who falsely reported that she had been robbed, thus effecting a "public mischief" by wasting police time and public money in investigating false leads. A few statutes go so far as to punish any false statement relating to an alleged offense. The American Law Institute in 1957 tentatively approved provisions on this subject in its *Model Penal Code* which would cover the offense of Manley, but would reach other oral misrepresentation to law enforcement officials only if it falsely implicates another person in crime. The danger sought to be avoided is that people might be subjected to criminal prosecution for denying their

own guilt; *e.g.*, when stopped by a policeman for a traffic offense or for denying knowledge of a crime under investigation, out of fear, friendship or mere reluctance to become involved.

PERKIN, SIR WILLIAM HENRY (1838–1907), English chemist, the discoverer of aniline dyes (*i.e.*, synthetic dyes prepared from coal tar), was born in London on March 12, 1838. He attended the City of London School and in 1853 entered the Royal College of Chemistry and studied under August W. von Hofmann, to whom he later became an assistant. He devoted his evenings and vacations to private investigations in a rough home laboratory, and was inspired by one of Hofmann's papers to undertake the synthesis of quinine. In the course of his experiments in 1856 he oxidized impure aniline with potassium dichromate and obtained a black product from which he was able to extract a bluish substance with excellent dyeing properties. This was the first aniline dye to be prepared, and it subsequently became known as aniline purple, tyrian purple, or mauve. A patent for the process of manufacturing the dye was taken out in 1856, and in 1857, with the aid of his father and an older brother, Thomas, Perkin set up works at Greenford Green, near Harrow, for the commercial production of mauve.

In 1858 he and B. F. Duppa synthesized glycine, the first amino acid to be prepared artificially, and in 1861 they synthesized tartaric acid. Perkin also had an important share in the development of artificial alizarin, which entirely replaced the red dye of the madder root. C. Graebe and C. T. Liebermann in 1868 prepared the substance synthetically from anthracene, but their process was not practicable on a large scale. In 1869 Perkin patented a commercially feasible process that secured for his Greenford Green works a monopoly of alizarin manufacture for several years. He also carried out investigations on other dyes and on flavouring materials, in the course of which in 1868 he synthesized the first artificial perfume, coumarin (*q.v.*), the odoriferous principle of woodruff and the tonka bean. He also investigated the constitution of salicyl alcohol, or saligenin.

About 1874 Perkin abandoned manufacture and devoted himself exclusively to research. In 1878 he discovered the Perkin reaction for the preparation of unsaturated acids (*e.g.*, cinnamic acid), which depends on the condensation of aromatic aldehydes with the salt of a fatty acid. Later he made a comprehensive study of the relation between chemical constitution and the rotation of the plane of polarization of light in a magnetic field and calculated the magnetic rotatory power of various elements and radicals.

Perkin was elected a fellow of the Royal Society in 1866 and was awarded the Royal Medal of the society in 1879 and the Davy Medal in 1889. He was knighted in 1906, on the 50th anniversary of his discovery of mauve.

He died at Sudbury near Harrow on July 14, 1907.

See also R. Meldola, *Jour. Chem. Soc.*, p. 2214 (1908); R. Meldola, A. G. Green, and J. C. Cain, *Jubilee of the Discovery of Mauve and of the Foundation of the Coal-Tar Colour Industry by Sir W. H. Perkin*, Perkin Memorial Committee (1906).

PERKINS, WILLIAM (1558–1602), one of the most noted English Puritan theologians and preachers, whose "sermons were not so plain but that the piously learned did admire them, nor so learned but that the plain did understand them," was born at Marston Jabbett, in Warwickshire. As many another Puritan divine, he was a graduate and a fellow (1584) of Christ's College, Cambridge. He was appointed lecturer in the Church of Greater St. Andrews, and it was there that he became famous for his powerful, learned and persuasive sermons.

Perkins was one of the few Puritan divines who attempted to write a systematic theology, and his was the most successful. He was widely quoted not only by Puritans but by non-Puritan Anglicans as well. Theologically, his *Golden Chain* represents a point of view very similar to that of John Calvin, but it was not simply an English version of Calvin's *Institutes*. Perkins prepared a catechism, wrote a powerful treatise defending the Church of England against Roman Catholicism (*The Reformed Catholike*, 1597), and produced numerous other writings.

Many of the key Puritan leaders such as William Ames and John Robinson were his students. In the 17th century, Perkins' theology probably was more widely read than that of any other Puritan. He died in 1602 and was interred in St. Andrew's church.

(JE. C. B.)

PERLIS, a state of the federation of Malaysia (*q.v.*), is the smallest and most northerly of the Malayan states with a seaboard on the Andaman sea. It is a constitutional sultanate. Until 1909 the state was a dependency of Thailand and then became one of the unfederated Malay states and a British protectorate; it was temporarily annexed by Thailand in 1942, but became a British protectorate again in 1945 until Malaya's independence in 1957. Area 310 sq.mi. Pop. (1961 est.) 101,357.

A large part of Perlis is a closely cultivated and densely settled plain formed by short erratic streams from the steep range in the northeast which combine into the Sungei Perlis river. To its north is the Nakawn (Sithammarat) range of cave-ridden limestones forming the boundary with Thailand. The eastern boundary is among similar mountains and barely 18 mi. from the sea, Malaya there being at its narrowest. The Perlis plain merges into freshwater swamp southward where it borders Kedah state.

Perlis has 49,000 ac. under paddy, the growing of which is the main occupation, the rice yield being the highest among the federation states. The coarse alluvium and erratic streams present frequent problems of water shortage for wet farming, so that regular crops of dry paddy are sown.

Malays form 78% of the total population and about 2,000 Chinese live in two or three mining villages outside the caves in the northern limestone range, within which irregular but rich pockets of alluvial tin have collected, the annual output being only about 220 tons.

Kangar is the state capital (pop. [1957] 6,064) and the sultan's residence is at Arau nearby. Kangar is a dispersed, open settlement, rather a village than a town. Kuala Perlis is an open settlement of fishermen who live in stilted houses built over the river mouth. It is inaccessible except by water. Inland and well away from the coastal swamps runs the Malayan railway, the single track of which crosses into Thailand at Padang Besar, the Malayan customs station, but the traffic has little economic significance for Perlis which has negligible exports. (E. H. G. D.)

PERLITE (PEARLSTONE), a natural glass generally of composition equivalent to granite with concentric cracks, such that the rock breaks into small pearllike bodies or "pebbles," and formed by rapid cooling of viscous lava or magma. A rhyolite (*q.v.*), it is commonly gray or greenish but is known to occur in shades of brown, blue and red. The lustre is pearly to waxy. Prior to about 1950 perlite was virtually unknown in commerce; but in the second half of the 20th century great deposits were worked in New Mexico, Nevada, California and other western states. Production outside the United States increased very slowly. When crushed perlite is rapidly heated to its softening temperature (*c.* 1,500°–2,000° F.), the contained water is converted to steam to form multitudes of tiny bubbles within the softened particles. The perlite is thus "popped" or suddenly expanded up to 20 times its original volume. This frothy glass may be considered an artificial pumice. Because of its very low density, heat-treated perlite is a substitute for sand in lightweight wall plaster and concrete aggregate. Due to its porous nature the material is ideal for heat and sound insulation and the manufacture of insulating wallboard and acoustic plaster. Other uses include lightweight ceramic products, filters and fillers.

The spherical or perlitic cracks which characterize this rock are generally considered to be due to contraction of the cooling glass. Some studies indicate the cracks form in response to hydration. The concentric arrangement of cracks causes small pellets of glass to separate from the rest of the rock. These "pebbles" may range up to an inch across but are usually the size of lead shot. They may appear as spherules widely distributed through

a sort of matrix, or they may be so closely packed as to mutually interfere and form polygon-shaped pellets somewhat resembling dried peas. The pearly lustre is attributed to reflections from the thin air films formed along the concentric fractures.

Some perlites are of intrusive origin (dikes), but others constitute major portions of lava flows. These glassy rocks may grade into nearly completely crystalline volcanic types. Like obsidian (*q.v.*) they may carry large crystals (phenocrysts) of quartz, alkali feldspar, and plagioclase and in some cases biotite or hornblende. Where phenocrysts are abundant the rock passes into vitrophyre. Crystalline bodies (*see* SPHERULITE; CRYSTALLITE) may also abound, and curved or wavy trains of these are common evidence of flowage of the viscous molten material.

Microscopically some of the small glass pellets show slight double refraction indicating a strained condition in the material, and doubly refracting glass at the contact with phenocrysts suggests strain due to differential contraction.

The chemical composition, index of refraction, and specific gravity of perlite are similar to those of obsidian. The water content, however, is considerably higher (generally 3%–4%), much having been added subsequent to consolidation. (*See* PITCHSTONE.)

Devitrification or conversion of the glass to a microscopically fine crystalline aggregate is usually initiated spontaneously along cracks or at the surfaces of phenocrysts and spherulites. Some minutely crystalline rocks show well-developed perlitic structure and undoubtedly represent completely devitrified perlite. The localization of spherulites along curved and concentric bands in certain glass-free rocks suggests a devitrified perlite with spherulitic growth along the perlitic cracks.

For chemical analyses of perlite and related glassy rocks, *see* PITCHSTONE. (C. A. CH.)

PERM, an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., formed in 1938, covers an area of 62,780 sq.mi. (162,600 sq.km.) and had a population (1959) of 2,992,876. The *oblast* lies on the western flank of the central Urals, extending from the crestline in the east, across the broad basin of the middle Kama to the Upper Kama uplands in the west. The northwest corner is occupied by the Komi-Permyak National Okrug (*q.v.*). The climate is continental, with a January average temperature of −17° C. (1° F.) and a July average of 17° C. (62° F.). Rainfall is from 20–22 in. a year in the west to 24–25 in. on the Urals. Almost the whole *oblast* is thickly forested with taiga of spruce, fir, pine and birch. Along the rivers are extensive flood plain meadows.

In 1959 a high proportion (59%) of the population were urban dwellers. There are 22 towns and 47 urban districts, the largest being Perm (629,118), the administrative centre, Berezniki (106,119), Solikamsk (82,874), Lysva (72,989), Kungur (64,796), Chusovoi (60,658), Kizel (60,687) and Krasnokamsk (54,715). This large urban population reflects the *oblast's* position as part of the Urals industrial area. Like the remainder of the Urals it is exceptionally rich in minerals. Most important are the huge deposits along the Kama of salt and potassium (among the largest in the world), which are the basis of the chemical industry of Berezniki, Solikamsk and Perm. Iron ore, copper and chromite supply the metallurgical and engineering industries found in most of the larger towns, especially Chusovoi and Lysva. Perm *oblast* is the northern end of the Second Baku oil field, drilled chiefly in the Chusovaya valley. Coal, fire clays and glass sands are also exploited. The forests supply paper, pulp and other timber-working industries. The northerly latitude and poor podsol soils give agriculture a minor role, except for intensive market gardening round the towns. Rye, potatoes and wheat are the main crops. There are several large power stations, notably the Kama hydroelectric plant, north of Perm city. (R. A. F.)

PERM (known as MOLOTOV from 1940 to 1957), a town and the administration centre of Perm *oblast* in the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on both banks of the Kama, 12 mi. below the Chusovaya confluence and about 700 mi. E.N.E. of Moscow. Pop. (1959) 629,118, making it the 17th town of the U.S.S.R.

In 1723 V. N. Tatishchev founded a copper-smelting works where the little stream Yegoshikhi joined the Kama at a small village, Bryukhanovo, founded in 1568. In 1781 the settlement of Yegoshikha became the town of Perm, although another town, Perm the Great (Perm Velikaya, now Cherdyn), had existed 150 mi. upstream since the 14th century.

Perm's position on the navigable Kama, leading to the Volga, and on the great Siberian highway (established in 1783) across the Ural mountains led to its development as an important trade and manufacturing centre. As industrialization proceeded in the Urals, especially after the Revolution, Perm grew considerably. Railways now focus on it from Solikamsk and the Kama chemicals region, from the Tura valley and Sverdlovsk in the Urals mining and metallurgical regions, and from Kirov in the west. Considerable transshipment takes place at Perm's busy river port. The town extends for 25 mi. along the high river banks. Its wide range of metallurgical and engineering industries produce equipment and machine tools for the petroleum and coal industries, agricultural machinery and telephones. There are large shipyards and an aircraft factory. A big refinery depends on petroleum from the immediate neighbourhood and oil is also piped from Almetyevsk. The chemical industry makes fertilizers, and timber working and flour milling are also carried on. Power is supplied by the 500,000-kw. hydroelectric plant just above the town.

Perm has the A. M. Gorky State university (founded 1916) and also has mining, pedogogical, pharmacological and medical institutes. Among its cultural institutions are opera and drama theatres and an art gallery with a noted collection of wood carvings. The town gives its name to the Permian geological series, first identified in this locality. (R. A. F.)

PERMAFROST, any part of the earth's mantle, including bedrock and all types of surficial materials, at any depth, maintaining a temperature of 0° C. or lower continuously for two or more years. Unfrozen ground is included as well as that commonly referred to as permanently frozen or, more correctly, perennially frozen ground.

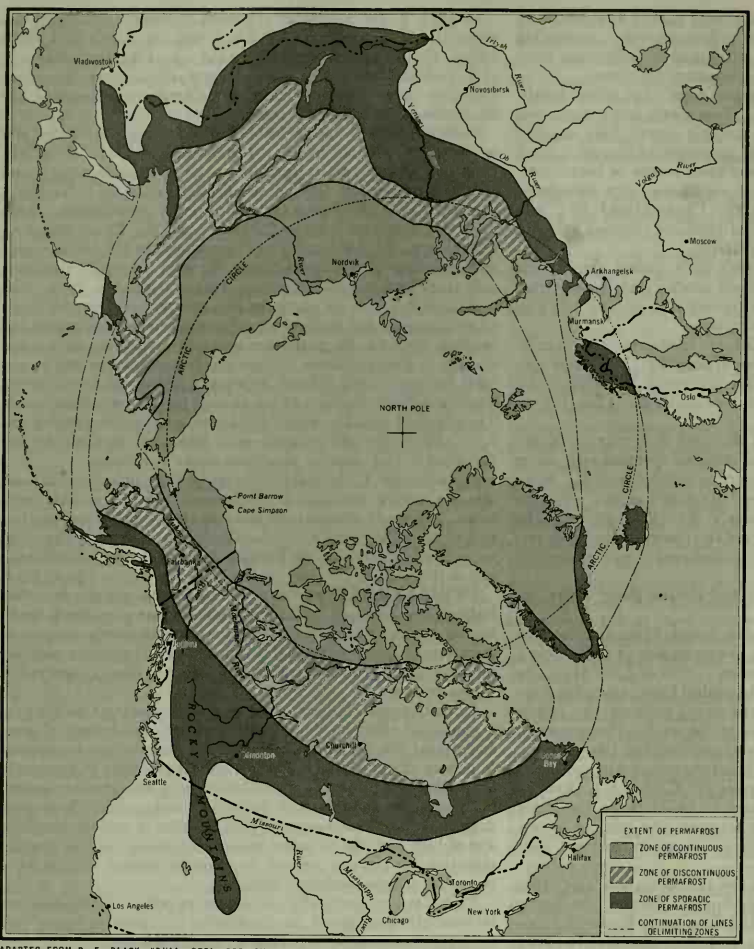
Permafrost and the geomorphic processes associated with it have a significant effect on the development and distribution of plant and animal life in areas where it occurs; its practical importance to human affairs is that it presents special problems in essentially all engineering projects. Its distribution is not precisely known but more than one-fourth of the earth's surface bears it in some degree. It is a phenomenon of high latitudes in both hemispheres and of high altitudes of major mountain systems, this relationship reflecting the primary control by climatic regimes typified by a perennial, negative radiation balance.

Permafrost is essentially continuous in polar regions, becomes increasingly interrupted in distribution at lower latitudes and occurs only sporadically toward its geographic limits. The continuous zone occupies an area of about 2,950,000 sq.mi. in the northern hemisphere and the entire 6,000,000 sq.mi. of Antarctica in the southern hemisphere. The discontinuous zone and sporadic zone include about 2,860,000 and 2,820,000 sq.mi., respectively, exclusive of alpine areas which may total 1,000,000 sq.mi.

Permafrost is thickest in the ice caps of Antarctica and Greenland where depths of several thousand feet are attained. Ground permafrost in the continuous zone generally ranges from 800–1,200 ft. in northern Alaska and 1,000–1,500 ft. in Siberia. Depths of about 2,000 ft. and 1,050 ft., respectively, have been measured at Nordvik, Sib., and Cape Simpson, Alaska. Estimates based on extrapolation of temperature profiles near Point Barrow, Alaska, indicate thickness of 670 ft. near the ocean shore and 1,330 ft. eight miles inland. In the discontinuous zone thickness is generally between 200–400 ft. and in the sporadic zone usually less than 100 ft.

Composition may be organic or inorganic; water, usually in the form of ice, furnishes the cementing medium of all otherwise unconsolidated materials. Well-drained deposits of gravels devoid of ice are termed dry permafrost. Within frozen ground brines with salt concentration several times greater than sea water qualify as permafrost but are unfrozen.

Ice occurs in many forms and variable amounts in ground



ADAPTED FROM R. F. BLACK, "BULL. GEOL. SOC. AMER.," VOL. 65, 1954

EXTENT OF THE ZONES OF PERMAFROST

permafrost and often exceeds all other materials in quantity. It is present as crystals of diverse size and shape, as grains, films, veins and lenses, and as large masses either horizontally or irregularly disposed or as vertically oriented, downward tapering wedges.

The origin of permafrost probably dates from the Pleistocene Epoch, although that of the continuous zone is in equilibrium with present climates and all materials added to the surface become part of the permafrost body. In the sporadic zone isolated bodies of permafrost are in large part relicts of historical climates. Such fossil permafrost, often deeply buried beneath surficial deposits, is long-enduring but is gradually reduced under conditions resulting in annual net transfer of heat to depth.

The production, preservation or dissipation of permafrost depends upon a complex of climatic factors (solar radiation, sky radiation, back radiation, winds, vapour pressure, precipitation, cloudiness), properties of surface (vegetation, albedo, snow, standing water), and physical properties of substrate components (organic and inorganic types, texture, structure, density, specific heat, thermal conductivity and diffusivity, thermal gradients). Both formation and preservation are enhanced by long, cold winters with low snowfall and clear skies and summers that are short, dry, cloudy and cool.

Overlying all frozen permafrost is a layer of variable thickness subject to thaw in warm seasons. This layer, called the active layer, may penetrate only the surface mat of vegetation or may extend to depths of a few inches to several feet. In continuous permafrost, thaw averages only one to two feet over large areas. The upper limit of frozen ground beneath the active layer, the permafrost table, is deepest on well-drained gravels lacking vegetation cover and topographically exposed to maximum insolation. Minimum thaw occurs in peats and fine-textured inorganic materials of low, poorly drained sites protected from the sun by topography, vegetation or snow cover. Sporadic bodies of permafrost are often buried by perennially thawed ground overlain by the seasonally frozen active layer. Such unfrozen layers, as well as islands of thawed ground surrounded by permafrost, are called (Russian) *talik*.

Aggradation and degradation of frozen ground produce characteristic landscape features and influence the course and techniques of man's activities. Extreme stresses and pressures induce heaving, thrusting, splitting, cracking, stirring and slumping of substrate materials. Stress is often relieved by polygonal arrays of vertical contraction cracks which become filled with ice. Repeated cracking and ice growth lead, in time, to development of ice-wedges several feet wide and many feet deep. Sand-wedges are formed similarly in conditions of great aridity.

Pressures deform sediments, inject fluid muds into voids and raise fine materials vertically to the ground surface or force them into the active layer. Forces of complex nature produce such surface features as mud spots or silt boils, frost blisters, ice mounds, and pingos. Pingos, hills composed largely of ice, originate in swampy lowlands and attain heights exceeding 200 ft. and diameters of several hundred feet. Noteworthy examples occur on the Mackenzie River delta, Can.

Thaw and gravity movements (creep, flow, solifluction, mass caving and slumping) of saturated materials across the water-lubricated permafrost table of all slopes are important geomorphic processes shaping arctic landscapes. Thaw and subsidence produce thaw lakes, cave-in lakes, thermokarst topography, beaded streams and surface expression of ice-wedge polygons.

This instability of surfaces is destructive to vegetation and interferes with orderly processes of soil formation. Low mounds, ridges and other relief structures differentiate biological assemblages largely by improving drainage and related environmental conditions. Plant remains contribute large annual increments of organic material to permafrost which constitutes a long-term cold-storage repository of both plant and animal fossils. This natural

refrigeration is employed for food preservation by man by the simple expedient of excavating cellars in the frozen ground.

Where permafrost occurs, procurement of potable water supplies, disposal of waste, mining, well drilling, and road, airstrip and building construction pose critical engineering problems. Avoidance of sites most subject to frost action and preservation of frozen ground by maintaining natural insulation and protection against transfer of heat from structures to the ground prevent costly damages or total loss of structures.

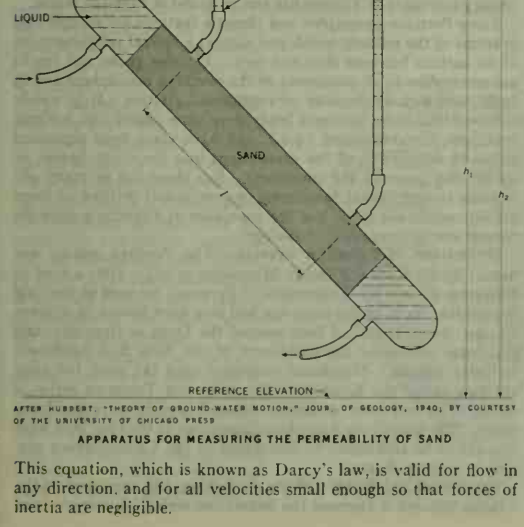
PERMANENT COURT OF INTERNATIONAL JUSTICE: *see* INTERNATIONAL COURT OF JUSTICE.

PERMEABILITY (FLUID). The permeability of a solid with respect to fluids is a measure of the facility with which fluids can penetrate or flow through the solid. Thus, of two solids, that one is the more permeable through which, under identical conditions, the greater quantity of a given fluid will pass in a fixed time. Solids owe their permeability to the existence of an internal porosity comprising a three-dimensional network of intricately branching and interconnecting channels. (*See* also GROUND WATER; HYDROLOGY.)

Darcy's Law.—The fluid permeability of a solid is defined and measured in terms of a flow experiment analogous to that illustrated in the accompanying figure. Here a liquid is made to flow through a porous solid into which two manometers along the same flowline have been tapped. It is found experimentally (and can also be deduced theoretically) that the volume of liquid, q, crossing the unit gross area normal to the flowlines in unit time is given by

$$q = (Nd^2)(\rho/\mu)(-g\partial h/\partial l)$$

in which N is a dimensionless shape factor and d a length parameter characterizing the geometry of the solid, ρ and μ are the density and viscosity of the fluid, g the acceleration of gravity, and $\partial h/\partial l$ the rate of increase with distance in the flow direction of the manometer height h with respect to a reference elevation.



AFTER HUBBERT, "THEORY OF GROUND WATER MOTION," JOUR. OF GEOLOGY, 1940; BY COURTESY OF THE UNIVERSITY OF CHICAGO PRESS

APPARATUS FOR MEASURING THE PERMEABILITY OF SAND

This equation, which is known as Darcy's law, is valid for flow in any direction, and for all velocities small enough so that forces of inertia are negligible.

Of the three groups of factors on the right-hand side of the above equation, the first, Nd^2, depends only on the pore geometry of the solid; the second, ρ/μ, is a property of the liquid; and the third, $-g(\partial h/\partial l)$, is the impelling force acting upon each unit of mass of the liquid. In the past, various combinations of these factors have been taken as a measure of permeability, but opinion and usage have gradually converged toward agreement that the term "permeability" shall pertain to a property of the solid only.

Of these factors, only the first, Nd^2 (often expressed by the symbol k), satisfies this condition, and it is accordingly taken as a proper measure of the permeability of the solid. Transposing the equation, the permeability of the solid is given by

$$k = Nd^2 = -\frac{q\mu}{\rho g(\partial h/\partial l)}$$

and its dimensions are $[L^2]$ (length)^2.

Units of Permeability.—Hence, in any consistent system of measurement in which one of the fundamental units is that of length, the unit of permeability is the square of the unit of length—for example, the square centimeter or the square foot.

For granular solids, if the mean grain diameter is taken as the characteristic length d, the factor N has an order of magnitude of 10^{-4}. Hence the permeabilities of clastic sediments, ranging from fine silts, with mean grain diameters of 10^{-4} cm., to coarse sands, with mean grain diameters of 10^{-1} cm., vary from about 10^{-12} to 10^{-6} sq.cm. Since the useful range of permeabilities of most sedimentary rocks is from about 10^{-12} to 10^{-8} sq.cm., there would be some advantage in having a practical unit defined by 1 practical unit $= 10^{-12}$ sq.cm.

Inconsistent units in wide current use are the Meinzer unit (5.42×10^{-10} sq.cm.) and the darcy (0.987×10^{-8} sq.cm.).

PERMEABILITY, MAGNETIC. The force between two magnetic poles varies as the product of the strengths of the poles, and inversely as the square of the distance between them. It depends also on the nature of the intervening medium. In the (centimetre-gram-second) electromagnetic system of units, unit pole is defined as one which repels an equal pole at a distance of one centimetre in empty space with a force of one dyne. Let F be the force between two poles of strengths m_1, m_2 at a distance r apart. Then, in a vacuum, $F = \frac{m_1 m_2}{r^2}$. More generally, $F = \frac{m_1 m_2}{\mu r^2}$. The constant μ depends on the medium, and is known as the permeability. The permeability may also be defined as the ratio of the magnetic induction B to the magnetizing force H; the induction being a measure of the magnetic force which would be exerted on unit pole placed in a narrow crevice in the medium, perpendicular to the direction of the magnetic force.

Thus $\mu = B/H$. The conception of permeability is due to Michael Faraday, who spoke of it as "conducting power for magnetism," and the term was introduced by William Thomson (later Lord Kelvin) in 1872.

Substances are divided into two main magnetic classes: diamagnetics, with the permeability μ less than 1; and paramagnetics with μ greater than 1. In diamagnetics the directions of the magnetization and the magnetizing force are opposite, in paramagnetics the same. For most substances the permeability differs very little from 1, and does not vary with the magnetizing field. A few paramagnetic substances, below certain critical temperatures, are ferromagnetic, having magnetic properties resembling those of iron. The permeability of ferromagnetics (which include iron, nickel and cobalt and some of their alloys) is a

function of the magnetic force, and generally depends on the previous history of the specimen. The permeability may be very large; the maximum for some generator steels and for iron-nickel alloys being greater than 100,000. A knowledge of the permeability characteristics of iron and iron alloys, in particular, is of great technological importance. Material having a high permeability for definite ranges of magnetic force is generally required in the construction of electrical machinery.

See MAGNETISM: *General Description of Magnetism; Magnetization and Permeability Curves.*

PERMEAMETER, an instrument for measuring magnetic permeability and other magnetic characteristics of substances. *See* MAGNETISM: *Measurement of Magnetic Quantities: Common Methods: Yokes and Permeameters;* PERMEABILITY, MAGNETIC.

PERMIAN PEOPLES, used by ethnologists and linguists outside of the Soviet Union to designate collectively two groups who speak closely related languages belonging to the Finno-Ugric family: Udmurt or Votyak and Komi or Zirian (Ziryen; *see* SYRVENIANS). Some Soviet scholars also distinguish a third Permian branch, the Komi-Permyak, who constituted (1960s) 70% of the 200,000 inhabitants of the Komi-Permyak national *okrug* (*q.v.*); but this tripartite division seems based on political considerations alone, for Permyak is simply the southernmost dialect of Komi (*see* FINNO-UGRIC LANGUAGES).

The common ancestors of the Udmurt and Komi separated from the westbound Volga-Finns (Cheremis and Mordvin; *qq.v.*) during the 1st millennium B.C., and continued as a uniform speech community for about 1,500 years thereafter. This period is known to specialists as the Permian (it has no connection, of course, with the geological period of the same name). The Permian community split into two branches during the 9th century A.D.

Udmurt Peoples.—Udmurt was spoken in the 1960s by more than 600,000 persons in the Udmurt Autonomous Soviet Socialist Republic (*q.v.;* capital, Izhevsk, an industrial centre), in the area between the Vyatka and Kama rivers. The Udmurt, organized in strong clan relations, are almost entirely peasants; each village was governed by a council of clan elders (*ken'esh*), which even farm collectivization did not succeed in wiping out. The Udmurt came under Russian administration in 1587, and were slowly converted to Christianity after 1740 under the influence of Archbishop Veniamin, who set up a church near the old Udmurt capital, Glazov.

Komi Peoples.—Komi was spoken by about 400,000 people in the 1960s, in an immense area, from the neighbourhood of the Udmurt northward almost to the Arctic Sea, and on the Kola Peninsula. The Komi Autonomous Soviet Socialist Republic (*q.v.;* capital, Syktyvkar) is the largest of all such republics in European U.S.S.R. Komi society has been shaped to a great extent by geographic location and climatic conditions, by the type of economy suitable for the area, and by Russian influence in cultural and political life. The location is responsible for the people's isolation and tardy progress; the uninviting climate protected them from extensive colonization until after World War II. The agricultural form of economy that prevailed for centuries remained dominant, though by no means uniform. After 1932 the Ukhta-Pechora region was gradually transformed into a mining and industrial area, and into a fuel producer for Leningrad industries; the modern development of the area is synonymous with that of three big undertakings: the oil trust, the coal trust, and the Northern Pechora Railway. The principal focus of the new Arctic mining activities is Vorkuta. In its vicinity the Komi changed after World War II from owners of large reindeer farms into workers on state farms, along with many Russian settlers. *See* also PERM.

PERMIAN SYSTEM, a geological term designating the uppermost system of rocks and the final period of the Paleozoic era (the era of ancient life)—a time believed to have begun about 235,000,000 years ago, and lasting about 25,000,000 to 35,000,000 years, as indicated in the accompanying geologic time chart.

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	1,000 Years
CENOZOIC ERA			
Quaternary	Recent	Modern man	11
	Pleistocene	Early man	1,000
Tertiary	Pliocene	Large carnivores	
	Miocene	Whales, apes, grazing forms	
	Oligocene	Large browsing mammals	
	Eocene	Rise of flowering plants	
	Paleocene	First placental mammals	70,000
MESOZOIC ERA			
Cretaceous		Extinction of dinosaurs	130,000
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals	160,000
Triassic		Appearance of dinosaurs	200,000
PALEOZOIC ERA			
Permian		Reptiles developed, conifers abundant	235,000
Carboniferous	Upper (Pennsylvanian)	First reptiles, coal forests	260,000
	Lower (Mississippian)	Sharks abundant	285,000
Devonian		Amphibians appeared, fishes abundant	320,000
Silurian		Earliest land plants and animals	350,000
Ordovician		First primitive fishes	400,000
Cambrian		Marine invertebrates	500,000
PRECAMBRIAN TIME			
		Few fossils	3,500,000–4,000,000

General Conditions of Permian Time.—The Permian was a time of crisis in world history. During much of preceding and succeeding Paleozoic and Mesozoic time, the continental areas were low and widely flooded by shallow seas, and the climate was equable over much of the earth. During the Permian, wide areas of the continents were emergent, there were extensive mountain chains and harsh climatic contrasts, with widespread deserts and continental glaciers; conditions were thus not unlike those of our modern era. Plant and animal life underwent many changes toward the end of Permian time, all species and many genera disappearing, some families and orders declining, others increasing in prominence, bringing about a change from the characteristic Paleozoic life to the characteristic Mesozoic life. (*See* also PALEOBOTANY; PALEONTOLOGY.)

Nevertheless, one should not think of these critical times as a cataclysm; their distinctive features began and ended gradually. Many of the mountain chains, such as the Appalachians of North America, had been growing since middle Paleozoic time. Permian marine invertebrates were not impoverished by the harsher conditions, but exceeded in variety and number those of some earlier periods. Many genera persisted into the Triassic, and the evolutionary forebears of Triassic life can be found in Permian strata.

Some Permian geographic and climatic features are inexplicable in terms of the modern world, and suggest a radical rearrangement of its surface between then and now. Permian rocks and fossils are much alike in all continents of the southern hemisphere and in India, and include deposits of continental glaciers. It is widely believed that these southern lands were once joined into a single continent, Gondwanaland (*q.v.*), and have since been separated either by foundering of the connections into the ocean basins, or by drifting apart of the continents. But there are as many objections to continental foundering or continental drifting as there are arguments for them, and the anomalies of Permian geography remain one of the riddles of geology.

Definition of Permian System.—The Permian system was named by Sir Roderick Impey Murchison in 1841, after a visit to European Russia, for the province of Perm not far west of the Ural mountains; rocks of the same age had long been known in western Europe, where they had been termed the Dyas in Germany, and had been considered the basal part of the New Red Sandstone in Great Britain. Murchison originally used the term for what are now called the Kungurian, Kazanian and Tartarian series, a sequence of red beds, evaporite deposits and fossiliferous limestone. The underlying Artinskian limestones of the type area were thought to be equivalent to limestones of the Carboniferous system in western Europe.

Later work has shown that the Artinskian, and even part of the Uralian beneath it (termed the Sakmarian series) is younger than

the typical Carboniferous farther west. Beds between typical Permian and Carboniferous were, for a time, designated as "Permo-Carboniferous," but this usage has passed out of favour, and general practice now is to extend the base of the Permian considerably below the base originally designated.

North American stratigraphers usually put the base of the Permian at the bottom of the Wolfcamp series and the zone bearing fossils of *Pseudoschwagerina*, a genus of the fusulinid family of Foraminifera (*q.v.*), which is about equivalent to the bottom of the Sakmarian in the U.S.S.R. It is thought that a boundary so placed can be recognized more readily than one at a higher level, and that it marks a significant stage in invertebrate evolution. European stratigraphers differ as to the classification of the Sakmarian, but some place it in the Carboniferous. On the other hand, the lower part of the German Dyas seems to be a continental equivalent of the Sakmarian and Wolfcamp.

The boundary of the Permian with the overlying Triassic can be drawn successfully in most marine sequences on the basis of characteristic invertebrate fossils, but its position is uncertain where the beds near the boundary are nonmarine and poorly fossiliferous—as they are in many places. In some areas the classification, as between Permian and Triassic, of formations and whole series has been much debated.

The classification of rocks in geologic systems is dealt with in GEOLOGY: *Historical Geology*. Additional information on the use of fossils in classifying and correlating deposits will be found in FOSSIL. *See* also SEDIMENTARY ROCKS; STRATIFICATION.

PERMIAN DEPOSITS

Deposits of Permian time are characterized by several distinctive assemblages, which reappear from one continent to another around the world. These types include:

(1) Red beds and other clastic rocks composed of fragments of pre-existing rocks, evaporites (gypsum, anhydrite, rock salt, potash minerals), dolomites and limestones. Red beds contain vertebrates (amphibians and reptiles) and plants, the limestones and dolomites an invertebrate fauna, mainly brachiopods, pelecypods and gastropods, relatively impoverished and without great diversity of genera and species. They were formed on extensive, flat, continental areas, partly on the surface of the land, partly in dessication basins, partly in shallow ephemeral seas, probably in a dry climate. Deposits of this type occur widely in the northern hemisphere, as in the U.S.S.R., Germany, Great Britain and the mid-continent region of North America.

(2) Marine deposits, in some areas of considerable thickness—shales, sandstones, and limestones, in places with thick reefs formed by lime-secreting organisms. Rocks of this type contain a large and diversified suite of marine invertebrates—fusulinids, bryozoans, brachiopods, pelecypods, gastropods, ammonoids, and the last of the trilobites. Such deposits are extensive in the southern part of the northern hemisphere and into the tropics—in Eurasia from the Mediterranean eastward to Indonesia in the ancient seaway called Tethys; in North America in western Texas, and Mexico.

(3) Volcanic rocks, mainly marine—lavas, pyroclastics and tuffs, with some nonvolcanic shales and limestones. Some beds contain marine invertebrates, such as fusulinids and brachiopods, and at some localities the fish *Helicoprion*. These deposits are characteristic of the most mobile parts of the geosyncline sur-

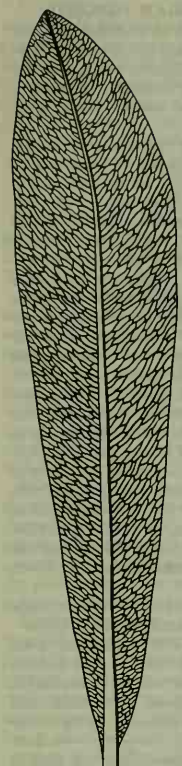

FIG. 3.—LEAF OF THE PERMIAN "TONGUE FERN" (GLOSSOPTERIS INDICA) THAT LIVED UNDER GLACIAL CONDITIONS

rounding the Pacific ocean, from California through British Columbia into Alaska, in Japan and New Zealand. An outlying volcanic sequence occurs at Las Delicias, Coahuila, Mex.

(4) Glacial and continental beds, generally with tillites near the base and a thick sequence of shales and sandstones above, with beds of coal. These deposits contain the distinctive seed fern, *Glossopteris*, and some reptiles. They are characteristic of wide areas in the continents of the southern hemisphere—southern Africa, eastern South America, Australia, Antarctica and peninsular India. Continental beds interfinger marginally in places with cold-water marine deposits containing the pelecypod *Eurydesma* and a few other invertebrates.

Permian of Europe.—Below are described some of the principal sequences of Permian rocks in the various continents, belonging to one type or another of the assemblages just listed.

The type Permian, in European Russia, lies in a broad basin that extends westward from the Ural mountains to Moscow. Thickness and nature of the rocks vary greatly across the basin, from thick clastic deposits on the east to thinner limestones on the west, but the general assemblage is of type 1, above. The following succession occurs (descending order):

EUROPEAN RUSSIA

Tartarian series.—Continental red beds, about 500 ft. thick, with many vertebrate fossils; upper part is Triassic.

Kazanian series.—In the west, marine limestone with invertebrate fossils, about 500 ft. thick, passing eastward into thicker nonmarine red beds.

Kungurian series.—Largely evaporites, with interbedded clays and marls; more than 2,500 ft. thick in the east, but thinning westward.

Artinskian series.—In the east, shales and sandstones, partly marine, partly continental, about 5,000 ft. thick, represented westward by upper part of limestones of Ufa plateau. Contains several zones of the fusulinid *Schwagerina*, as well as many ammonoids and brachiopods.

Sakmarian series.—In Ufa plateau, limestones 500 to 750 ft. thick, with large reef bodies, containing the fusulinid *Pseudoschwagerina*, the gastropod *Omphalotrochus*, the ammonoid *Artinskia* and other invertebrates. Passes eastward into much thicker sandstones and conglomerates. Formerly included in the Artinskian of the Urals and in the Uralian elsewhere. Lies on earlier Uralian limestones that contain the fusulinid *Triticites*.

In Germany, where the Permian has been termed the Dyas, the section is somewhat thinner, but of the same general type as in Russia. The sequence is as follows (descending order):

GERMANY

Zechstein (*Thuringian*).—At base, a copper-bearing black shale a few feet thick, the Kupferschiefer, overlain by 100 ft. of dolomitic limestone containing an impoverished marine invertebrate fauna. Above it, several thousand feet of evaporites, which give rise to the salt domes of northern Germany, and which are mined for rock salt and potash at Stassfurt.

Upper Rothliegende (*Saxonian*).—Red sandstones and shales with much interbedded lava.

Lower Rothliegende (*Autunian*).—Shales, red beds and some coal, containing *Walchia*, *Callipteris* and other plants. A much more local deposit than the two higher divisions, but locally attaining a thickness of several thousand feet.

The Permian of Great Britain resembles that of Germany. Its magnesian limestone appears to be the same as the dolomitic limestone of the lower Zechstein, and is likewise overlain by evaporites.

Permian of North America.—In North America the standard Permian section is that in west Texas, where most of the sequence is marine and highly fossiliferous (type 2, above), and attains a thickness of 10,000 ft. Best exposures are in the Guadalupe and Glass mountains lying, respectively, on the northwest and south sides of the Delaware basin, a depositional area of Permian time. There the sequence is as follows (descending order):

NORTH AMERICA

Ochoa series.—Evaporites, mainly anhydrite below and rock salt above, the latter containing workable potash-bearing layers. At top, a widespread thin dolomite (Rustler) with the only fossils in the series (brachiopods, gastropods, pelecypods). Overlain with hiatus by Upper Triassic, so relation to lowest Triassic is unknown.

Guadalupe series.—Marine sandstone, shale and thin limestone in Delaware basin, passing marginally in upper part into thick barrier reefs (Capitan limestone). Contains the fusulinids *Parafusulina* and *Polydiexodina*, the ammonoids *Waagenoceras*, *Timorites* and *Xenaspis*, and a rich and varied brachiopod fauna.

Leonard series.—Mainly black shale and thin-bedded limestone in Delaware basin (Bone Spring formation), passing marginally into limestone banks and small reefs. Contains the fusulinids *Schwagerina* and *Parafusulina*, the ammonoids *Perrinites* and *Medlicottia*, and numerous brachiopods, including *Dictyoclostus ivesi*.

Wolfcamp series.—In Glass mountains, shale with thin beds of limestone and conglomerate, but farther northwest a more solid body of limestone (Hueco). Contains the fusulinids *Pseudoschwagerina* and *Schwagerina*, the ammonoid *Artinskia*, the gastropod *Omphalotrochus*, and numerous brachiopods. Lies on Virgil series of Pennsylvanian (Upper Carboniferous), with *Triticites* and *Uddenites*, in places with angular unconformity.

North and northeast of the Delaware basin in the midcontinent area of central Texas, Oklahoma and Kansas, marine beds largely give place to red beds and evaporites; the Permian is of type 1.

Toward the northwest, also, the marine beds pinch out. At the Grand canyon in northern Arizona the Permian is about 2,000 ft. thick and consists, below the Triassic, of the Kaibab and Toroweap limestones, Coconino sandstone, Hermit red shale and Supai red beds. Only the Kaibab and Toroweap (with *Dictyoclostus ivesi* and *D. bassi*) are marine; the Coconino is an ancient dune deposit and the strata below are flood-plain deposits, with plant remains and reptile and amphibian tracks. Much of the sequence is of Leonard age, but the lower nonmarine beds include Wolfcamp equivalents.

Farther north, the Park City and Phosphoria formations form an interfingered set of deposits 200 to more than 1,000 ft. thick, which cover wide areas in contiguous parts of Utah, Wyoming, Idaho and Montana. They lie on Pennsylvanian, are overlain by early Triassic and cover a wide span of Permian time; parts are as old as the Leonard or Wolfcamp, but the main body, with the *Spiriferina pulchra* brachiopod fauna, is of Guadalupe age. The Park City and Phosphoria beds interfinger eastward with the red beds of the midcontinent area and are bordered on the west by volcanic rocks of the circum-Pacific belt.

Permian of Southern Hemisphere.—Permian rocks of the southern hemisphere belong mainly to type 4, above. The section in South Africa is representative and forms the lower part of the Karroo system. The Permian part of the Karroo varies from a few thousand feet thick in most of the region to nearly 15,000 ft. in

FIG. 4.—EXAMPLE OF THE PERMIAN RECORD IN NORTH AMERICA, THE GUADALUPE MOUNTAINS IN WEST TEXAS, WHERE 1,300-FT. CLIFFS OF CAPITAN REEF LIMESTONE CAP 3,000 FT. OF DARKER PERMIAN SANDSTONE

the Cape mountains on the south. It consists of the following (descending order):

South Africa

Beaufort series.—Interbedded sandstones and shales, probably floodplain deposits, containing reptiles at many levels and a few *Glossopteris* in the lower part. Reptiles indicate that only lower part of series is Permian, the higher being Triassic.

Ecca series.—Mainly shale and mudstone, but with interbedded sandstone in places, and coal measures in the middle in Transvaal and Natal. Contains abundant *Glossopteris-Gangamopteris* flora.

Dwyka series.—In the south, thick tillites, with shales below and above, lying conformably on upper beds of the Cape system. Farther north, the series is missing entirely in places; in others, only the tillite is present, lying on a striated pavement of pre-Cape rocks. Upper shales contain sparse marine fossils in southwest Africa, including the pelecypod *Eurydesma* and the reptile *Mesosaurus*.

The tillites of the Dwyka are boulder-bearing clays which are moraines of a continental ice sheet; striae indicate that its centre was in Transvaal or farther north, from whence the ice moved south and southwest, the thick tillites on the south probably being a terminal moraine deposited at the edge of the continent. (*See* also Africa: *Geology.*) The Dwyka tillites record a climax of glacial conditions, but relations elsewhere indicate that the period of refrigeration was prolonged; in eastern Australia boulder beds of glacial origin are interspersed through more than 10,000 ft. of section.

Correlation of the Permian rocks of the southern hemisphere with those of the northern is difficult because the *Glossopteris* flora and cold-water marine fauna of the former extend but rarely into rocks of the latter region. Age of the tillites is especially disputed, geologists placing them variously entirely in the Carboniferous, entirely in the Permian or partly in both. In northern India (Salt Range and Kashmir) and in western Australia, tillites, cold-water marine beds and beds with *Glossopteris* flora are followed by beds with marine fossils which can be correlated with the Artinskian (Leonard) of the northern hemisphere, thus suggesting that the climax of glaciation was during Sakmarian (Wolfcamp) time. In other areas, where tillites extend through a greater thickness of strata, glaciation may have begun earlier and ended later than the Sakmarian. *See* also references under "Permian System" in the Index.

Bibliography.—General information about the Permian system is carried in most textbooks on geology and paleontology (*see* Geology: *Bibliography;* Paleontology: *Bibliography*). PERNAMBUCO, a northeastern Atlantic state of Brazil. Area 37,946 sq.mi. (98,280 sq.km.); pop. (1960) 4,136,900. It comprises a comparatively narrow coastal zone, a high inland plateau and an intermediate zone formed by the terraces and slopes between the two. Its surface is much broken by the remains of the ancient plateau which has been worn down by erosion, leaving escarpments and ranges of flat-topped mountains, called *chapadas*, capped in places by horizontal layers of sandstone. The coastal zone is low, well-wooded and fertile. It has a hot, humid climate, relieved to some extent by the southeast trade winds. This region is locally known as the *matas* (forests). The middle zone, called the *caatinga* or *agreste* region, has a drier climate and lighter vegetation. The inland region, called the *sertão*, is high, stony and dry and frequently devastated by prolonged droughts (*sêcas*). The climate is characterized by hot days and cool nights and is generally considered healthful. There are two seasons, a rainy season from March to June and a dry season for the remaining months.

The rivers of the state include a number of small plateau streams flowing southward to the São Francisco river, and several large streams in the eastern part flowing eastward to the Atlantic. The largest of the coastal rivers are the Goiana, the Capibaribe, the Ipojuca, the Sirinhaém and the Una.

The state of Pernambuco is, for the most part, agricultural, the lowlands being devoted to sugar and fruit, with coffee in some of the more elevated localities; the *agreste* region to cotton, tobacco, Indian corn, beans and stock; and the *sertão* to grazing and in some localities to cotton. Sugar, molasses, rum (*aguardente* or *cachaça*), tobacco and fruit are largely exported. Coconuts, cacao, bananas, mangoes and other tropical fruits are produced in profusion, but the production of foodstuffs (beans, Indian corn, mandioca, etc.) is not sufficient for local consumption. Mangabeira rubber is collected to a limited extent, and piassava fibre is an article of export. Orchids are also collected for export in the districts of Garanhuns and Timbaúba. Cotton weaving and cigar making are leading manufacturing industries, after the large *engenhos* devoted to the manufacture of sugar and rum. The railways of the state concentrate at the port of Recife.

The capital of the state is Recife; pop. (1960) 788,569. There are a number of large towns in Pernambuco; the most important are: Bom Conselho, a town of the higher *agreste* region, Caruarú, Garanhuns, Goiana, Limoeiro, Olinda, the old colonial capital and episcopal see, Timbaúba and Vitória. These towns range in population from about 7,000 to more than 100,000.

Pernambuco, at its inception in 1526, was settled by Christovão Jacques, who founded a settlement on the Rio Iguarassú that was afterward abandoned. The first permanent settlement was made by Duarte Coelho Pereira at Olinda in 1530, and four years later he was granted a *capitania* of 50 leagues extending from the mouth of the São Francisco northward to that of the Iguarassú. Adjacent to this grant on the north was the *capitania* of Itamaracá, granted to Pero Lopes de Souza, which covered the remainder of the present state. The *capitania* of Pernambuco was ably governed and took an active part in the expulsion of the French from the trading posts established along the coast northward to Maranhão, and in establishing Portuguese colonies in their places. In 1630 Pernambuco was occupied by the Dutch and continued under their rule until 1654. Although an active guerrilla warfare was waged against the Dutch during a large part of that period, they did much to promote the agricultural and commercial interests of the colony, especially under the wise administration of Maurice of Nassau. As a result of their victory over the Dutch the people of Pernambuco developed a strong regional feeling and resentment of all foreign domination, including the Portuguese.

In 1817 Pernambuco was the scene of a revolutionary outbreak, which resulted in the temporary separation of the present states of Alagôas and Rio Grande do Norte, Ceará and Paraiba. There was another insurrection in 1822 when the Portuguese were expelled; and in 1824 dissatisfaction with the arbitrary proceedings of Dom Pedro I at Rio de Janeiro led to a separatist revolution for the formation of a new state, to be called the Federação do Equador. There was another outbreak in 1831 and frequent disorders to 1848, which culminated in another unsuccessful revolution. The population of the Pernambuco *sertão* became noted for its turbulent, lawless character, due partly to the distance from the coast where the bulk of the population is concentrated, partly to difficult means of communication and partly to the fact that this remote region became the refuge of criminals from the coast towns. PERÓN, JUAN DOMINGO (1895–), Argentine general and president (1946–55), led one of the most significant of Latin America's 20th-century revolutions. Born Oct. 8, 1895, in the province of Buenos Aires, Perón entered military school in 1911 (when the Argentine army was advised by a German military mission) and rose to captain in 1924. He had a minor part in the military-conservative revolution of 1930 which overthrew the democratically elected president, Hipólito Irigoyen, and which began a period of considerable political repression and increased

state authority. During these years Perón served as an observer with the Italian army (1938–39).

Popular dissatisfaction with the widespread social and economic injustice and with the corrupt regime of Pres. Ramón S. Castillo, together with profound divisions of opinion over Argentina's neutral position in World War II, formed the background for a *coup d'état* that overthrew Castillo in June 1943. An army clique which included Colonel Perón and which was known as the GOU (Group of United Officials) engineered this coup. The provisional governments during the following three years came increasingly under the domination of Perón, who at the outset shrewdly took the minor post of secretary of labour and social welfare. By 1945 he had added the offices of vice-president and war minister, and it was clear that he was bidding for undisputed power based on the support of the underprivileged labourers (the *descamisados,* or "shirtless ones") and on control of the army.

Ousted briefly from all his positions by a coup of the liberals (Oct. 1945), Perón, aided by the bold and loyal Eva Duarte (*see* below) whom he married on Oct. 26, 1945, emerged from a week's imprisonment on Oct. 17, 1945, and in a dramatic appeal to the people voiced his determination to lead them to victory in the pending presidential elections. After a campaign marked by violent repression of the rights of the liberal opposition by the Perón-controlled police and strong-arm squads, he was elected president in Feb. 1946 by a plurality of 250,000 out of approximately 5,000,000 votes.

Assuming office in June 1946, Perón set out on a course of nationalism, industrialization, statism, encouragement of anti-U.S. feeling and favouring of the proletariat. Basing his action on a doctrine of social welfare which he called *justicialismo,* Perón showered needed improvements upon the labourers in the form of wage increases and fringe benefits. He stimulated rapid industrialization and nationalized the banks, the railroads (which he purchased from the British in 1947) and other utilities, and financed public works on a large scale. Money and equipment for these costly innovations—and for the graft which corroded his regime—came from the foreign exchange accumulated by Argentina during World War II and from the profits of Instituto Argentino de Promoción del Intercambio (I.A.P.I.), a state trading institution which controlled agricultural production. Perón dictated the political life of the nation by his command of the army, the police, the labour unions and the Peronista party. He nearly eliminated constitutional liberties such as the free press, as demonstrated in his seizure of the newspaper *La Prensa* in 1951.

Re-elected by a slightly larger margin in 1951, Perón modified some of his policies, particularly his pell-mell industrialization, his disregard of agriculture and his anti-U.S. propaganda. He was overthrown by an army-navy revolt (Sept. 16–19, 1955) led by democratically inclined officers who reflected general discontent with inflation, corruption, tyranny, demagoguery and the anti-Roman Catholic policies that Perón had begun in 1954. The dictator fled to exile in Paraguay, eventually settling in Spain. He continued to influence Argentine political life through his numerous followers. His supporters, allowed on the ballot for the first time since 1955, polled about 35% of the vote in 1962, but the armed forces immediately annulled the election. In 1963 the Peronistas joined to form a united front with the Intransigent Radical party of former president Arturo Frondizi. When the military leaders disqualified many of the front's candidates for electors, both Perón and Frondizi urged their followers to cast blank ballots in the election as a protest. About 17% of the voters did so.

In December 1964 Perón made an attempt to enter Argentina, but his plane was turned back at Rio de Janeiro, and he returned to Spain. The indifference with which most Argentinians reacted to the incident was considered a blow to the Peronistas.

Eva María Duarte de Perón (1919–1952), wife of Juan Perón, was a powerful political figure in her own right. Born May 7, 1919, in a small town in the province of Buenos Aires, "Evita," as she was popularly known, moved to the city of Buenos Aires in the 1930s and played minor roles in motion pictures and on radio. She met Colonel Perón after the 1943 revolution that first brought him onto the national political scene, and she had much to do with organizing the labourers of Buenos Aires for the mass demonstration (Oct. 17, 1945) that marked his release from political imprisonment and cleared the way for his drive to the presidency. Evita and Perón were married the following week. When her husband assumed the presidency in June 1946, Evita devoted her boundless energy to extending his revolutionary dictatorship into areas peculiarly her own. She headed the feminine branch of the Peronista party, directed the Eva Perón Social Aid foundation (a vast fount of charity for the underprivileged, who did not observe that the funds came from the state and not from Evita personally), controlled the newspaper *La Razón,* in fact ran the ministry of health and in effect was the minister of labour, thus helping her husband control the labour unions, which formed a pillar of his authority. Her bid to become vice-president at the time of her husband's re-election (1951) was blocked by the army. She died July 26, 1952, in Buenos Aires.

PÉROTIN (Perotinus) (d. 1238?) French composer of sacred polyphonic music who worked at Notre Dame in Paris toward the end of the 12th century and who now is believed to have been responsible for the introduction into Western music of writing in four parts. Nothing is known of his life. Though he is one of the composers of the time who did not remain anonymous, his identity remains in doubt. The name Pérotin, or Perotinus, is held to be a diminutive of Pierre, or Petrus, and it has been suggested that he was one of the figures of whom records have survived at Notre Dame, *Diaconus Petrus praecentor* (d. Paris, 1197) or, more probably, *Petrus succentor* (d. Paris, 1238). Early references to Pérotin are in a treatise by the 13th-century English theorist known as Anonymous IV (*c.* 1275), who refers to him as Perotinus the Great. These references are reproduced in E. Coussemaker's *Scriptorum de musica medii aevi,* vol. i (1864–76).

Until the middle of the 20th century research on the work of Pérotin as the founder of 12th-century polyphony remained in an elementary state. It is established, however, that he was the composer of two four-part polyphonic pieces, *Viderunt* and *Sederunt.* Another four-part composition, *Mors,* is also believed to be the work of Pérotin. Anonymous IV also attributes to him various vocal works for one and three voices. Armand Machabey and other medievalists showed that the four-part polyphonic works of Pérotin were revolutionary, since the religious music of the 12th century was almost entirely in the form of the two-part organum (*q.v.*). In the compositions of Pérotin the liturgical chant in the tenor is often heard not against one voice but against two or three voices, which provide highly decorative vocalizations. Among other achievements Pérotin enlarged upon the work of Léonin, who was his predecessor; he was also responsible for rhythmic innovations; and his works contain an early form of hocket, which was developed in the French motets of the following century.

PEROVSKITE, essentially calcium titanate, orginally found in a chlorite schist at Achmatovsk in the Ural mountains and named after Count L. A. Perovski. Crystals are lustrous, yellow to brownish black, highly twinned cubes or octahedra (actually orthorhombic very nearly cubic symmetry). Common occurrences are as accessory constituents of basic or alkalic-basic igneous rocks or at metamorphic contacts of these rocks with limestones. The composition is $CaTiO_3$. Rare-earth elements, sodium, potassium and iron substitute for Ca, and niobium and tantalum substitute to a considerable extent for Ti in the natural mineral.

The name perovskite is also applied to an important crystal structure family, including calcium titanate ($CaTiO_3$) and related natural and synthetic compounds, all possessing similar pseudocubic or cubic structures. Element substitutions in natural perovskite suggested many of the chemical variations later shown to

be possible by synthesis. The importance of this family to the electrical industry was recognized with the discovery of ferroelectricity in barium titanate, $BaTiO_3$. Members of this family, including the titanates, zirconates and niobates, have become very important to the entire electronics industry, where they are used for their high dielectric constants and as transducers (transformers of electrical energy into mechanical energy) capable of withstanding high temperatures (*see* ULTRASONICS). (RU. R.)

PEROXYACIDS are oxyacids which contain one or more peroxide groups, –O–O–, or they may be regarded as oxyacids in which an OH^- group has been replaced by an –OOH group. They are formed by boron, carbon, titanium, zirconium, germanium, tin, nitrogen, phosphorus, vanadium, columbium, tantalum, sulfur, chromium, selenium, molybdenum and tungsten. Some are described under the corresponding elements; *e.g.*, peroxysulfuric acid and peroxydisulfuric acid under SULFUR. (J. B. Ps.)

PEROZ: *see* FIRUZ.

PERPENDICULAR PERIOD, in architecture, the final phase of English Gothic (*c.* 13th–17th centuries). The term was first used in 1817 by Thomas Rickman, who divided English Gothic into three stylistic phases: Early English, Decorated (or Curvilinear) and Perpendicular.

Perpendicular style is characterized by a predominance of vertical lines in the decorative work or traceries which appeared on windows and wall paneling (*see* TRACERY). The vertical lines were crossed by horizontal ones so as to form rectangular patterns which suggested the possibility of endless repetition. For this reason, Edmund Sharpe in 1851 introduced the term Rectilinear to characterize a style he believed to be a reaction to the Curvilinear. Although this belief was accepted for nearly a century, it is now known that the Curvilinear, which began in England in 1192 with the Eleanor crosses, was actually contemporaneous with the first Perpendicular design in the undercroft of St. Stephen's chapel in Westminster. Its stylistic continuation can be found a generation later in the eastern part of Gloucester cathedral (*c.* 1331–50). In structure, the Perpendicular tendency was toward the reduction of wall surface, the increase of window area, the continuity of vertical lines and supports and the lavish development of decorative vaulting ribs. Later, structural vaulting ribs were eliminated altogether and cut-stone traceried fan vaults were substituted (*see* ARCH AND VAULT).

Timber-trussed ceilings and roofs were developed to a point of great perfection and richness, as in Westminster hall, London (1395–99), and in countless simpler parish churches; *e.g.*, Chipping Norton, Holy Trinity, Hull. Also constructed in this style were many beautifully outlined and lavishly detailed church towers, usually square and without spires. Those of Gloucester cathedral (1450–57), Magdalen college, Oxford (1492–1505), the central tower at Canterbury (1495) and the west towers of York (1432–70) are typical. In decorative detail the Perpendicular style is marked by the introduction of the four-centred, or Tudor, arch, the covering of wall surfaces with ranges of traceried panels, chiefly rectangular, the general flatness of molding profiles, the enclosing of door and window arches within a rectangular hood mold and the replacement of an earlier naturalism in carved ornament by a rather dry and incisive though, at times, mechanical conventionalism. It was a style so vital that it yielded but slowly to the influx of Renaissance ideas, and, particularly in Oxford, its effect was felt in building well into the 17th century. *See* GOTHIC ARCHITECTURE: *Late Gothic; see* also references under "Perpendicular Period" in the Index.

PERPETUAL MOTION is the action of a device that in theory will move by itself forever, without any supply of energy from outside. In some cases the motion is supposed to be independent of any external agent, but frequently the force of gravity plays an essential part in the scheme. More often, perpetual motion is taken to imply a machine which, once in motion, will produce external work for an indefinite period, either without any supply of energy or by drawing heat energy from the immediate surroundings. The possibilities of perpetual motion have fascinated many and retain great historic interest because, as a result of the vain quest for it, there grew up one of the great generalizations of physical science: the principle of conservation of energy (*see* ENERGY).

The U.S. Patent Office refuses to accept any patent application for perpetual motion without a working model, and "understands the term 'perpetual motion' to mean a mechanical motion creating energy, that is, a machine doing work and operating without the aid of any power other than that which is generated by the machine itself, and which, when once started, will operate for an indefinite time." The British Patent Office refuses any application that claims perpetual motion on the ground that this is obviously contrary to well-established physical laws.

Such devices as self-winding clocks or watches might appear to exhibit perpetual motion, but do not. Some are wound by the action of the wearer's movements on a small weight (*see* WATCH). Others have been devised to be wound by the variation of atmospheric pressure or temperature.

A mechanical device that would move perpetually without any supply of energy would violate the principle of conservation of energy. Although this fundamental law of science was not formally enunciated until the 19th century, many earlier workers realized that mechanical perpetual motion was a contradiction of nature; this was clearly stated by Thomas Savery (*c.* 1650–1715), who made the first commercially successful steam engine. Earlier (1586) the Dutch mathematician Simon Stevin (*q.v.*) based his demonstration of the laws of equilibrium on an inclined plane on the impossibility of perpetual motion.

By the first law of thermodynamics (*q.v.*) the law of conservation holds for changes of heat energy. This, however, would not prohibit the construction of a machine that should draw heat from, say, a large body of water, such as a lake, and convert it to work. This would amount to perpetual motion, since removal of energy to lower the temperature of a lake 1 mi. wide and 10 ft. deep by 1° C would supply heat corresponding to more than 10,000,000 horsepower hours, and heat from the sun and the surroundings would prevent the temperature of the lake from falling indefinitely. By the second law of thermodynamics, however, it is impossible to obtain a continuous supply of work by cooling a body to a temperature below that of the coldest of its surroundings. For example, the use of the heat of a boiler for doing work requires a colder body such as a condenser. This second law denies the schemes of a 20th-century school of perpetual motionists who claim somehow to use the heat of bodies at atmospheric temperature to produce a continuous supply of work.

The perpetual motionist of another modern school declares that he fully recognizes that work cannot be derived by any machine without a supply of energy of some kind, but that his machine, being supplied with energy, will produce a greater amount of energy. Such an inventor may claim that conservation of energy and the first and second laws of thermodynamics lack universal validity but that so far, for one reason or another, he has been unable to construct an engine to demonstrate this practically.

It has been suggested that if a substance could be found which cut off completely the action of gravity, it would be easy to achieve perpetual motion by holding a sheet of the substance beneath a weight being lifted and by removing the sheet while it fell. A similar scheme has been suggested as feasible if a substance could be found that would cut off completely the action of magnetism. These ideas neglect the work necessary to introduce and to remove the substance. Similarly, although a grounded conducting plate will cut off the attraction of an electrostatically charged body, a perpetual motion device has not been made on these lines with electric charges.

The words of the civil engineer Henry Dircks (1806–73) concerning claimants to perpetual motion, continue to be echoed. "A more self-willed, self-satisfied, or self-deluded class of the community, making at the same time pretension to a superior knowledge, it would be impossible to imagine. They hope against hope, scorning all opposition, with ridiculous vehemence, although centuries have not advanced them one step in the way of progress."

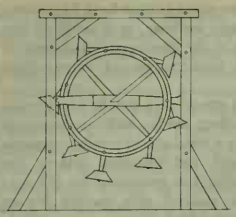

FIG. 1.—V. DE HONNECOURT'S OVERBALANCING WHEEL

The first recorded attempt to construct a perpetual motion machine apparently was that of Villard de Honnecourt (*q.v.*), an architect of the 13th century, who noted that skilful workmen often tried to contrive a wheel that would turn of itself. His crude sketch (fig. 1), offered as a solution to the problem, is the forerunner of a large number of different types of overbalancing wheel. The absence of perspective in this ancient picture makes the wheel appear in the same plane as the supporting frame, whereas actually it must be at right angles to it. The principle is clear, although not very well represented; the weights at the end of the hinged arms, which are on the ascending side of the wheel, are to lay flat against its circumference, while those on the descending side are to project. Actually, of course, however the weights and their attachments are designed, the moments of the gravitational forces about the wheel's axis will be the same.

A numerous class of machines that utilize the force of gravity on rigid solids includes many descendants of Honnecourt's wheel. Fig. 2 represents one described by Thomas Young (*q.v.*) in a lecture in which he denied the possibility of perpetual motion, saying: "To seek for a source of motion in the construction of a machine betrays a gross ignorance of the principles on which all machines operate." He pointed out that in every such overturning wheel, although some of the weights are more distant from the axis than others, there is always a correspondingly smaller number of weights on the side on which the wheel has the greater moment. Probably the most elaborate of such wheels, with 13 weights (each operated by a complicated system of levers, pulley wheels, and chains) was put forward in 1751, apparently by the printer Edward Cave (*q.v.*).

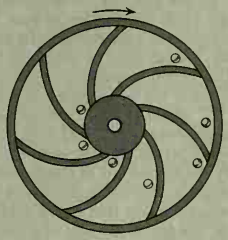

FIG. 2.—OVERTURNING WHEEL DESCRIBED BY THOMAS YOUNG

The most famous perpetual motion wheels were those of Edward Somerset, 2nd marquess of Worcester (1601–67) and of Johann Ernst Elias Bessler (1680–1745), generally known as Orffyreus. Worcester's wheel of 14 ft. diameter carried 40 weights of 50 lb. each. In *A Century of . . . Inventions . . .* (1633) he wrote that all the weights of the descending side of the wheel were always farther from the centre than those of the mounting side and yet that the numbers on both sides were equal. He did not claim that perpetual motion was the result, but said that Charles I, with various court personages, observed the trial and the behaviour of the weights (*c.* 1638–39), and concluded: "Be pleased to judge the consequence." This wheel was extensively discussed by authors from J. T. Desaguliers onward and in particular by Dircks, without definite conclusion. It seems that the wheel was started by hand, that the weights behaved as Worcester said, and that, having a large moment of inertia, the wheel continued to rotate without noticeable slowing during the brief period of its inspection, although coming to rest later.

Worcester's is the only contemporary record of his wheel, but there is a copious literature about that of Orffyreus, or rather about his last one, for he appears to have constructed more than one. In particular the Dutch physicist W. J. Gravesande (1688–1742) wrote a description of the externals of the wheel; the inventor would not permit him to see the inside. It was a drum about 12 ft. in diameter and 14 in. thick, consisting of a wooden framework covered with canvas. It turned on iron axes which Gravesande was convinced did not transmit the motion. He wrote that the wheel continued to rotate for two months (November 1717–January 1718) in a carefully locked room in the castle of Charles, landgrave of Hesse-Kassel. He spoke favorably of the invention but recorded that he had no opportunity of inspecting the working parts of the machine or of learning anything about the principles upon which it was constructed. It is stated that Orffyreus admitted that his wheel was set in motion by weights. A servant of the inventor later declared that she had effected the turning of the wheel from an adjoining room, but her word has been doubted. According to an apparently reliable account, Orffyreus broke his machine because of what he considered to be the impertinent curiosity of Gravesande. There is an atmosphere of charlatanry, mixed with a little madness, about the affair.

The overturning wheel rests on ignorance of the laws of mechanics. Another class, involving liquids, is based upon ignorance of the laws of hydrostatics and hydrodynamics. Waterwheels that hopefully would raise water to feed their own millstreams frequently occur in the history of the subject. John Wilkins, bishop of Chester, in his *Mathematicall Magick . . .* (1648) described a machine in which water was to be raised by an Archimedean screw kept in rotation by the falling of the raised water (*see* ARCHIMEDES, SCREW OF). His account is often quoted as if he believed this to be a solution of the problem of perpetual motion, but he wrote: ". . . upon trial and experience I found it altogether insufficient for any such purpose." Another device (fig. 3) founded on the erroneous belief that the pressure at a given distance below a large surface of liquid is greater than that below a small surface, was proposed (1686) by the Abbé de la Roque, proprietor of the *Journal des sçavans*, and subsequently by later inventors. The hope was that the water in the wider part would force up the water in the narrower part to produce continuous circulation. Most of the hydraulic schemes put forward up to the present are more elaborate but just as unsuccessful. Some involve capillary action; *i.e.*, surface tension (*q.v.*), as that (fig. 4) conceived by the artillerist Sir William Congreve (1772–1828). EFG represents an inclined plane that supports pulleys, an endless sponge band abcd, and jointed heavy weights in band ABCD. With the expectation that ab would become saturated with water while the weights were squeezing ad dry, the unfulfilled hope was that the extra weight in segment ab would produce continuous motion in the direction of the arrow.

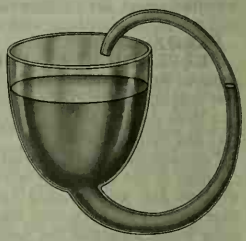

FIG. 3.—ABBÉ DE LA ROQUE'S HYDRODYNAMIC DEVICE

Wilkins classified the methods by which perpetual motion had been sought in his time as chemical, magnetic, and gravitational. As a chemical method he cited a reaction supposed to produce small particles which, if sealed in a vessel, would move continually. This, and self-moving liquids discussed by a few others, were never much pursued, probably because they were not adapted to drive machines. A magnetic method mentioned by Wilkins depended upon an implied sudden diminution of magnetic attraction at a certain point when a steel ball was attracted up an inclined plane by a lodestone; more complicated schemes involving magnetism were equally untenable, including designs that involve substances which cut off the magnetic field.

With the development of the Volta pile (*see* BATTERY), two piles could be arranged to attract a light ball from one to the other alternately. The amount of energy used is so small and its origin in the chemical action of the pile so little obvious, that it is surprising that more has not been heard of this method. Probably the fact that it was not adapted to make any kind of machine prevented projectors from putting it forward. In the Clarendon Laboratory at Oxford University

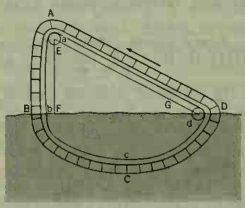

FIG. 4.—WILLIAM CONGREVE'S SPONGE AND WEIGHT MACHINE

there are two large piles, their upper ends, of opposite polarity, being connected by a wire and their lower ends each bearing a bell. A small brass ball suspended by a silk thread oscillates from one to the other, producing a sound. This has been operating since 1840, and probably is the most perpetual of all so-called perpetual motion devices, but in principle it is no different from an electric clock run by a battery (*see* ELECTROCHEMISTRY).

The availability of liquid air started a fresh crop of schemes for perpetual-motion engines that could do appreciable work. Liquid air obviously can be used as a boiler fluid to power an engine without a furnace of any kind. The trouble is that more energy is required to make the liquid air than can be derived from it.

There have been notable perpetual-motion frauds, one of the most celebrated being John W. Keely's motor which created a sensation in the U.S. about 1870. The inventor supported his claim with an abstruse theory that included such expressions as hydro-pneumatic-pulsating-vacuo-engine and etheric force. Using fraudulent demonstrations, Keely collected considerable sums of money in support of his project. He declared at one time that with one gallon of water he could propel a steamship from New York to Liverpool.

Modern techniques for obtaining power from atomic energy (*q.v.*) are sometimes cited as examples of perpetual motion, with the idea that they create energy from nothing. However, nuclear processes clearly consume atomic fuels, and in this sense are analogous to the burning of ordinary fuels.

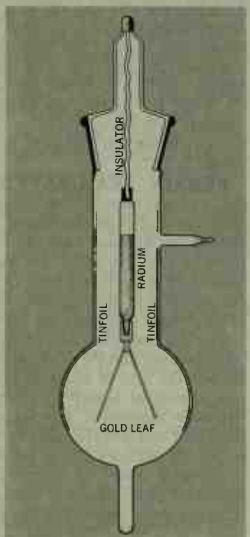

FIG. 5.—R. J. STRUTT'S RADIUM CLOCK

The first example of the use of nuclear energy to produce motion was in 1903, when R. J. Strutt (later fourth Baron Rayleigh) created a sensation with an apparatus called the radium clock. Two fine gold leaves, arranged as in the electroscope much used at that time in laboratories, hung from a thin-walled vertical glass tube containing radium, the whole being held by an insulating support inside an evacuated glass vessel (fig. 5). Attached to the inner walls of this vessel were two grounded tinfoil strips, so arranged that when the gold leaves became heavily charged and strongly repelled each other, they touched these strips and were discharged. As it lost beta particles through the thin glass, the radioactive preparation became charged, the leaves diverged, discharged, and collapsed; the process repeated indefinitely. The half-life of the radium fuel being about 1,620 years, the motion of the device may have seemed perpetual.

Strutt recorded that "Lord Kelvin was wildly enthusiastic about it and persisted in calling it my 'perpetual motion,' for at the time he advocated the view that radium drew its energy from the surroundings at the same temperature, contrary as he admitted to the second law of thermodynamics." However, it soon became firmly established that energy is released as the radium nucleus is transformed. The phenomenon is not perpetual motion produced by subtle design without a source of energy. The modern breeder reactor (*see* PLUTONIUM: *Uses*) constitutes an immensely more energetic version of Strutt's experiment.

The sun's radiant heat may be utilized by some direct method; the tides may be harnessed; or some other source of energy may be made to produce systematic mechanical motion for the service of man. But a machine to produce ordered motion by itself in complete isolation or to use the heat of its surroundings as a source of energy without a colder sink is so improbable that it is most likely to be impossible of realization.

Phin, *The Seven Follies of Science*, 3rd ed. (1912); S. R. Smedile, *Perpetual Motion and Modern Research for Cheap Power* (1962).

PERPETUITY, literally, means an unlimited duration; but in law it refers to a provision which is in breach of the rule against perpetuities. For more than seven centuries, Anglo-American law has assumed that social interest requires freedom in the alienation of property. (Alienation is, in law, the transferring of property by voluntary deed and not by inheritance.) When English land conveyancers in the late 16th century invented a form of conveyance designed to make land inalienable forever, the courts held it an invalid human attempt to rival the permanence of God. Thus they utilized the word "perpetuity" to describe such an invalid limitation, borrowing it from the Latin phrase *in perpetuum*, used constantly in the Scriptures with reference to God's eternal continuance (Ps. 103:9; Job 14:20).

The term perpetuity thus became, in law, the antithesis of freedom of alienation. It took little effort to extend the application of the word from present interests of perpetual duration to future interests which would prevent the alienability of the affected property for "too long" a time. The applicability of this regulation to future interests became clear by the end of the 17th century. The next century and a half (1687–1833) were spent by English courts in determining how long was "too long" for the purposes of this rule.

By this masterpiece of judicial legislation, the permissible period for the tying up of property became fixed at the lifetimes of human beings alive when the conveyance was made plus 21 years, plus one or more periods of gestation, to allow for the inclusion of persons conceived but not yet born at any of the times which were important in applying the permissible period. (*See* REAL PROPERTY AND CONVEYANCING, LAWS OF.) This period corresponded with the English marriage settlement, under which the land would be tied up until the eldest son of the marriage was of full age. The rule invalidated any interest in property, whether real or personal, which, when created, might take longer than this period to vest in the donee; it regarded possible, rather than actual events. This became the "common-law rule against perpetuities," and this rule, with slight modifications, now operates in England and in a very large percentage of the American states with respect to dispositions of both land and personal property. It serves simultaneously to assure the alienability of property by the end of a not inconveniently long period of time, and to set an outer limit on the power of the dead hand to control the future.

In 1830 the New York Legislature adopted statutes substantially shortening the permissible period and applying the rule's regulation not only to future interests but also to the duration of the most common form of private express trusts. This statutory innovation spread in varying degrees to 13 other states (Arizona, California, Idaho, Indiana, Kentucky, Michigan, Minnesota, Mississippi, Montana, North Dakota, Oklahoma, South Dakota, and Wisconsin) and the District of Columbia. The century following, however, witnessed a gradual abandonment of the New York leadership on this point, and even New York itself returned largely to the common-law permissible period in 1958. In England, in 1956, the Lord Chancellor's Law Reform Committee's Fourth Report recommended far-reaching reforms of the rule, including the substitution of actual events for possible events. Since the whole rule rests on social policy, exceptions to it based on social policies recognized as superior have gained acceptance as to perpetual trusts for burial lots, trusts for pension plans, charitable gifts, and some other less frequent types of conveyance.

PERPIGNAN, a town of southern France, capital of the *département* of Pyrénées-Orientales and the seat of a bishopric, is situated on the Tet river, 15 mi. from the Spanish frontier and 7 mi. inland from the Mediterranean sea, in luxuriant fruit and wine country. It is dominated to the southwest by the Canigou massif (Mont Canigou, 9,137 ft.). Pop. (1962) 82,626.

Perpignan was one of the leading fortified towns of the Pyrenees. The citadel (17th–18th centuries) dominates it from the south; this incorporates the palace begun by the kings of Majorca (13th–14th centuries), a notable specimen of Catalan Gothic architecture. There is also the Castillet, a charming rose-brick château, mostly of the 14th century, which contains a folk museum. A fine complex of civic buildings testifying to Perpignan's commercial and administrative importance includes the Hôtel de Ville or town hall (13th–17th centuries) and the Loge de Mer (begun 1397). The chief religious monument is the 14th- to 15th-century cathedral of St. Jean. A notable museum is the Musée Rigaud in the 17th-century university building; it contains canvases by Hyacinthe Rigaud (1659–1743), a native of Perpignan.

Perpignan has a flourishing trade in fruit, wine and vegetables. There are also ceramic and other craft industries, including doll manufacture. The town's easy access to the Mediterranean beaches, thermal baths and mountains makes it a leading tourist centre; and by virtue of its good rail, sea (via Port-Vendres, 19 mi. S.E.) and air communications it is also a junction for travelers for southern Europe and north Africa. There are air routes to London, Paris and the Balearic islands.

The first mention of Perpignan occurs in the 10th century, when it was called Villa Perpiniani. It rose to importance on becoming capital of the medieval Spanish countship of Roussillon. The kings of Aragon held it from 1172 until 1278, and the kings of Majorca until 1344. It then passed between Aragon and France until 1475, when it was occupied by troops of the French king Louis XI, but it did not become permanently French until it was secured in 1659 by the treaty of the Pyrenees. (Y. H.)

PERRAULT, CHARLES (1628–1703), French writer of fairy tales and influential literary controversialist, was born in Paris, Jan. 13, 1628. After studying law, he began work under his brother Pierre but won some reputation about 1660 as a writer of burlesque verse and amourous poems. From 1663, when J. B. Colbert assumed the protection of literature and the arts, Perrault did important work under him, envisaging the establishment of a general academy such as Napoleon was later to set up in the Institut. Elected to the Académie Française in 1671, he died in Paris on the night of May 15–16, 1703.

Perrault is chiefly remembered for his charming fairy tales, *Histoires ou contes du temps passé* (with the alternative title *Contes de ma mère l'Oye*), published in 1697 but written, according to the abbé J. B. du Bos, sometime earlier, to amuse Perrault's children. The tales are notably free from the affectation and spurious naïvete that disfigure other fairy tales of the period. (*See* CHILDREN'S LITERATURE: *Fairy Tales and Fantasy.*) In his own time, however, Perrault was most important as the champion, in the Académie Française, of the "moderns" against the "ancients" (*see* ANCIENS ET DES MODERNES, QUERELLE DES). His poem *"Le Siècle de Louis le Grand,"* read to the Académie on Jan. 27, 1687, was an outspoken polemic that provoked Boileau to protest forcefully on the spot. Perrault, however, maintained his attitude in his *Parallèle des Anciens et des Modernes* (1688–92).

The most systematic and the most radical of the moderns, he believed that the human mind made continuous progress and that a nation's literature corresponded to its state of civilization, so that ancient literature was inevitably coarser and more barbarous than modern. Shocking to his contemporaries and to later critics, Perrault's extremism makes his thought a historic landmark in the revolt against the humanist tradition.

Three of his four brothers are also noteworthy: PIERRE (1611–*c.* 1680), an official in the revenue department who upheld the moderns against the ancients in the preface to his translation of Alessandro Tassoni's *La Secchia rapita* (*Le Seau enlevé*, 1678) and in *Critique des deux tragédies d'Iphigénie d'Euripide et de M. Racine* (unpublished); CLAUDE (1613–1688), a doctor of medicine whose activities as an architect were derided by Boileau in *L'Art poétique*, book iv (1674); and NICOLAS (1624–1662), a doctor of theology who inclined to Jansenism.

See P. Bonnefon, "Charles Perrault . . . ," three articles, *Revue d'histoire littéraire de la France* (1904–05), a most important study; also A. Adam, *Histoire de la littérature française au XVII^e siècle*, vol. iii and v (1952–56). (AE. A.)

PERRERS, ALICE (d. 1400), mistress of the English king Edward III, probably belonged to the Hertfordshire family of Perrers, although some sources state that she was of humble birth. She married Sir William Windsor, king's lieutenant in Ireland (1369–72) and governor there (1373–76). She entered the service of Edward's queen, Philippa of Hainaut, before 1366. Her intimacy with the king began about 1367. A few years after the queen's death (1369) Alice was given her robes and jewels. In May 1376 her removal from court was demanded by the commons in the Good parliament. It was alleged that she had drawn £2,000 or £3,000 a year from the royal coffers, and that she frequently sat on the judges' bench and "maintained" (supported) her friends in their lawsuits. A decree of banishment and forfeiture was passed against her. Although the bishops had sworn to excommunicate her if she returned, they remained passive when she was brought back to court later in 1376 by the king's brother, John of Gaunt. The parliament of Jan. 1377 reversed the sentence against Alice and she was with the king when he was dying (June 1377). After Edward's death she fled from court and the government seized more than £2,500 belonging to her; two chroniclers assert, however, that she took with her the rings from the dead king's fingers. In Dec. 1377 she was again condemned, this time before the lords, for defying the ordinance of 1376 and continuing to interfere with the course of justice. In 1378 she appealed against her conviction, on technical grounds, and the sentence was reversed in 1379.

PERRIN, JEAN BAPTISTE (1870–1942), French physicist, who was awarded the Nobel prize for physics in 1926 for his extensive studies on the motion (called Brownian movement) and distribution of small particles suspended in a liquid, was born at Lille, on Sept. 30, 1870. He was educated at the École Normale Supérieure in Paris and from 1898 to 1940 was professor of physical chemistry in the University of Paris. He was elected a member of the French Académie des Sciences in 1923 and was president in 1938. His researches were mainly concerned with colloids, Brownian movement and the determination of absolute molecular weights. He was the first to establish experimentally (1895) that cathode rays consist of negatively charged particles. His researches on Brownian movement gave experimental confirmation of Albert Einstein's theoretical studies in which it had been shown that such suspended particles should follow the gas laws even to the extent of giving a means of determining Avogadro's number (N), an important physiochemical constant, namely, the number of molecules in a gram molecule of any gas, the number obtained by Perrin being 6.8×10^{23}. His book, *Les Atomes* (1913; 3d ed., 1940), describing this work, became a classic. He died in New York city on April 17, 1942. (D. McK.)

PERRON, (CHARLES) EDGAR DU (1899–1940), Dutch man of letters and influential critic, was born at Meester Cornelis, Dutch East Indies, on Nov. 2, 1899, the son of a planter. In 1921 his family (which was of French origin) moved to Europe and settled in Brussels. Du Perron himself lived in Montmartre for some time, among the Paris artists, where he experimented with modernistic poems and stories. In his novel *Een Voorbereiding* (1927; "A Preparation") he gives an account of this period of apprenticeship. Later, with his friend Menno ter Braak (*q.v.*), he founded the publication *Forum* (1932–35) which turned against the exaggerated worship of beautiful form rather than distinctive content, and judged literature by standards of honesty and common sense.

Du Perron did much to publicize the works of André Gide and of his friend André Malraux, and translated into Dutch the latter's novel *La Condition humaine* which had been dedicated to him. His collected essays, *De smalle Mens* (1934), deal with the precarious position of the self-sufficient personality in the face of

the threatening collective attitude of left and right. His poems, collected in *Parlando* (1941), contain so-called *poesie parlante*, which achieves a new effect through the use of everyday words. Shortly before World War II du Perron spent a few more years in the Dutch East Indies, collecting material for his books on Multatuli published in *De Man van Lebak* (1937). He returned to the Netherlands and died at Bergen, Neth., on May 14, 1940. His collected works were published in 1954.

See G. H. 's-Gravesande, *E. du Perron* (1947); H. A. Gomperts, *Jagen om te Leven* (1949). (Gd. W. Hs.)

PERROT, SIR JOHN (*c.* 1527–1592), lord deputy of Ireland from 1584 to 1588, whose boldness in action provoked extremes of admiration or hatred and marred much of his work, was generally reputed to be the son of King Henry VIII. His mother was Mary Berkley, who later married Thomas Perrot. John Perrot, as he was named, was probably born at Harroldston, Pembrokeshire. He was attached to the household of William Paulet, 1st marquess of Winchester, and was knighted at the coronation (1547) of Edward VI. Though imprisoned by Mary I on a charge of harbouring heretics, he was soon released and was later granted the castle and lordship of Carew in Pembrokeshire. Early in the reign (1558–603) of Elizabeth I he was entrusted with the naval defense of south Wales. He was appointed lord president of Munster in Nov. 1570, and did much to pacify the province after the rebellion (1569) of James (Fitzmaurice) Fitzgerald. He withdrew to England in July 1583 and resigned his Irish office.

Sir John returned to Ireland as lord deputy in 1584. The end of the Desmond war (1579–83) provided the opportunity for the government to confiscate land for plantation by English settlers (*see* IRELAND: *History*). But the area made available was not utilized adequately and the colony acquired only a thin superstructure of English landlords. Perrot's work in regard to Connaught land titles was more satisfactory. He succeeded in inducing the great and small gentry to compound the services due to the crown by paying instead a fixed money rent.

Always ready for military action, Perrot opposed the renewed ambitions of Sorley Boy MacDonnell (*q.v.*), who was supported by the MacLeans from Scotland. He managed to restrict the use of Scots mercenaries by the Irish lords, but obtained the submission (1586) of Sorley Boy only by excessive concessions.

In the Irish parliament of 1585–86 much legislation introduced by Perrot was blocked in the house of commons. The English government rejected his advice to punish the opposition leaders and a compromise was provided which gave the Dublin government greater freedom in drafting legislation.

A plan of Perrot's to convert the revenues of St. Patrick's cathedral, Dublin, for a projected new university, precipitated a violent quarrel between him and Archbishop Adam Loftus of Dublin. Loftus successfully opposed the plan and then brought about Perrot's recall in 1588 on a charge of treasonable negotiations with Philip II of Spain. The correspondence is now known to have been forged, but he was found guilty and imprisoned in the Tower, where he died in Sept. 1592.

See Sir James Perrott, *Chronicle of Ireland, 1584–1608*, ed. by H. Wood (1933); C. McNeill, "The Perrot Papers," *Analecta Hibernica*, vol. xii (1943). (R. D. Es.)

PERRY, BLISS (1860–1954), U.S. writer, chiefly known as an essayist and critic, was born at Williamstown, Mass., Nov. 25, 1860. He graduated from Williams college in 1881 (A.M., 1883), continuing his studies at the universities of Berlin and Strasbourg. He was professor of English at Williams college, 1886–93; professor of oratory and aesthetic criticism at Princeton university, 1893–1900; professor of English literature at Harvard university, 1907–30; and Harvard lecturer at the University of Paris, 1909–10. He was editor of the *Atlantic Monthly*, 1899–1909. His autobiographical *And Gladly Teach* appeared in 1935. Perry died at Exeter, N.H., Feb. 13, 1954.

PERRY, MATTHEW CALBRAITH (1794–1858), U.S. naval officer, who concluded the first treaty between Japan and the United States, was born at South Kingston, R.I., April 10, 1794. He was commanding officer (1838–40) of the "Fulton II," first U.S. steam warship. In 1843 (with the honorary rank of commodore) he commanded a squadron that was sent to Africa, under the terms of the Webster-Ashburton treaty, to aid in suppressing the slave trade. During the Mexican War, Perry commanded a naval force that captured Frontera and Tabasco, thereby cutting off Mexico from Yucatan; and in March 1847, his unit carried out a bombardment that permitted the landing of troops at Veracruz.

In March 1852, Perry was appointed commander of a naval expedition to be sent to Japan to induce the government to establish diplomatic relations with the U.S. After studying the situation, Perry concluded that Japan's traditional isolation policy would be altered only if superior naval forces were displayed and if the Japanese officials were approached with a "resolute attitude." He decided "to demand as a right, and not to solicit as a favour, those acts of courtesy which are due from one civilized country to another. . . ." With two frigates and two sailing vessels he entered the fortified harbour of Araga on July 8, 1853. He refused to obey Japanese orders to leave and sent word that if the Japanese government did not delegate a suitable person to receive the documents in his possession, he would "go on shore with a suitable force and deliver them personally, be the consequences what they might." A high Japanese official was finally dispatched and, amid much ceremony, the U.S. documents were delivered. Perry then reported that he would return the following year, with a much larger naval force, to receive a reply to Pres. Millard Fillmore's request for a treaty.

In Feb. 1854 Perry reappeared in Edo (modern Tokyo) bay with more ships than before and on March 31 concluded the first treaty between the United States and Japan. The presents given by Perry to celebrate the occasion filled several boats and included a model railway, telegraph instruments, modern guns, telescopes and other items that served to impress the Japanese with the technological and scientific achievement of the west.

The treaty merely assured better treatment of shipwrecked seamen and permitted U.S. ships to obtain fuel and supplies at two Japanese ports. But it demonstrated the military government's inability to enforce its traditional isolation policy and thus contributed to the collapse of the feudal regime and to the modernization of Japan.

The success of the expedition made Perry a recognized authority on the far east. Through his writings and speeches he stressed the danger of British and Russian expansion and urged that the United States play a more active role in the orient. He died in New York city, March 4, 1858.

PERRY, OLIVER HAZARD (1785–1819), U.S. naval officer who became a national hero when he defeated a British squadron in the Battle of Lake Erie during the War of 1812, was born on Aug. 23, 1785, at South Kingston, R.I. Appointed midshipman in 1799, he saw service in the Mediterranean and was commander of a gunboat flotilla when the War of 1812 began. In February 1813 he was sent to complete the building of the squadron at Erie, Pa.

On Sept. 10, 1813, Perry, with nine vessels, engaged Capt. Robert Heriot Barclay, who commanded six British warships. Perry was greatly superior in short-range firepower, but only slightly superior at long-range, and light wind prevented him from closing quickly with Barclay. After his flagship "Lawrence" had suffered heavy casualties and been reduced to a defenseless wreck, Perry transferred to the "Niagara," a sister-ship, and sailed into the British line firing broadsides, soon forcing its surrender. With U.S. control of Lake Erie thus regained, Perry sent his famous message to Brig. Gen. William Henry Harrison: "We have met the enemy and they are ours. Two ships, two brigs, one schooner, and one sloop." The battle had begun 8 mi. from Put-in-Bay and ended 14 mi. to the northwest, near West Sister Island.

Perry died at sea of yellow fever on Aug. 23, 1819, while returning from Venezuela.

See C. J. Dutton, *Oliver Hazard Perry* (1935); C. S. Forester, *The Age of Fighting Sail* (1956). (R. J. Do.)

PERRY is an alcoholic beverage made by fermenting pear juice. Mostly it is produced in those northern countries, of temperate climate, where it is easier to grow pears and apples than grapes. Dessert pears cannot be used for perry; the fruit must have "vintage" qualities, and where the soil is suitable for cider (*q.v.*) orchards it will also bear perry orchards successfully. In England, in Herefordshire, Worcestershire, Gloucestershire, and in parts of Monmouthshire, Somerset, and Kent, perry orchards flourish; they like best a sandy loam. In France only a little perry is produced in Brittany, but in Germany it is preferred to cider. Formerly there was a large production of perry in the eastern states of the United States.

Many English varieties of perry pears, such as Barland, Holmer, Huffcap, and Taynton Squash, can be traced to the end of the 17th century. The origin of some varieties, for instance Cheat Boy, Longland, and Blakeney, cannot be traced, but others can be dated to the 18th century (such as Buff) or to the early 19th century (Aylton Red). It was then that perry lost popularity; the orchards became derelict and were widely uprooted.

After World War II popular taste in Britain adopted sparkling perry, and pear juice is imported from Switzerland, as it possesses "vintage" quality when blended with English pear juice.

See R. Hogg, *The Apple and Pear as Vintage Fruits* (1886).

(C. C. H. F.)

PERSE, SAINT JOHN (pseudonym of MARIE RENÉ AUGUSTE ALEXIS LÉGER) (1887–), French poet and diplomatist, who was awarded the Nobel Prize for Literature in 1960. He was born at Saint-Léger des Feuilles, Guadeloupe, March 31, 1887, studied at the Universities of Bordeaux and Paris and in 1914 entered the diplomatic service. He went to China and was successively consul at Shanghai and secretary at Peking. In 1921 he attended the Washington Disarmament Conference as an expert on Far Eastern affairs. He was later secretary to Aristide Briand. In 1933 he was appointed secretary general of the Foreign Ministry, with the rank of ambassador. Dismissed from office in 1940, and deprived of French citizenship by the Vichy government, he went to the U.S., where he worked in the Library of Congress. He continued to live there after the liberation of France, although his French citizenship was restored and he retained an estate on the Riviera.

His early poetry, published before his diplomatic career gained momentum, includes *Éloges* (1904–08) and *Images à Crusoe* (1909), and shows the influence of Symbolism, though he later developed a more personal style. The language of his poetry, admired, especially by poets, for its precision and purity, is difficult, and he has made little appeal to the general public. His best known early work is the long poem *Anabase* (1925; Eng. trans. by T. S. Eliot, 1930). In the poems written in exile—*Exil* (1942), *Vents* (1946), *Amers* (1957), and *Chronique* (1960)—he achieved a more deeply personal note and, by some American readers, was regarded as an embodiment of the French national spirit: intellectual yet passionate, deeply conscious of the tragedy of life, a man of affairs with an artist's feeling for perfection and symmetry.

PERSEPHONE (Latin PROSERPINA), in Greek mythology the daughter of Zeus and Demeter, the goddess of agriculture, and wife of Hades, king of the underworld. In Homer, Persephone is queen of the underworld, and there is no mention of her relationship to Demeter. Hesiod, in his *Theogony*, is the first to relate that she was the daughter of Demeter and was carried off by Hades (*q.v.*). The Homeric Hymn to Demeter tells the story in full: Persephone was gathering flowers in the Vale of Nysa when she was seized by Hades and removed to the underworld. Her mother sought her in vain, sorrowing, and after nine days asked the all-seeing sun-god, Helios, if he knew what had happened. After learning the truth, Demeter ceased, in her misery, to be concerned with the harvest or the fruitfulness of the earth, so that widespread famine ensued. Zeus therefore intervened, commanding Hades to release Persephone to her mother. But Persephone had taken food in the underworld—a single pomegranate seed—so she could not be completely freed but had to remain one-third of the year with Hades, spending the other two-thirds with her mother.

One of the variants of the name Persephone is Persephassa, a form with a pre-Hellenic suffix that suggests that she was a pre-Hellenic deity, no doubt a goddess of the dead. If this is so, her connection with Demeter came later, when she was identified with Kore (the Greek word for "maiden"), the young grain-goddess and daughter of Demeter; Demeter and Kore were the leading goddesses in the Eleusinian mysteries (*see* MYSTERY), with which the Homeric Hymn to Demeter is connected. The story that Persephone/Kore spent four months of each year in the underworld was no doubt meant to account for the barren appearance of Greek fields in full summer (after harvest) before their revival in the autumn rains when they are plowed and sown.

Persephone also appears in the Orphic myth of Zagreus, her son by Zeus, who as a child was torn apart by Titans (*see* DIONYSUS). *See* DEMETER (with bibliography); *see* also references under "Persephone" in the Index.

PERSEPOLIS (Old Persian PARSA; modern TAKHTE-E JAMSHID), an ancient capital of the Achaemenian kings of Persia, situated about 32 mi. NE of Shiraz in Fars province, southwest Iran, not far from the point at which the small river Pulvar (Rudkhaneh-ye Sivand) flows into the Kor (Cyrus) river. The site is marked by a large terrace with its east side leaning on Kuh-e Rahmat ("the Mount of Mercy"). The other three sides are

FRANCES MORTIMER—RAPHO GUILLUMETTE

RUINS OF THE RESIDENTIAL PALACE OF DARIUS THE GREAT AT PERSEPOLIS; NEAR THE WEST TERRACE WALL, JUST SOUTH OF THE APADANA

formed by a retaining wall, varying in height with the slope of the ground from 14 to 41 ft.; on the west side a magnificent double stair in two flights of 111 easy stone steps leads to the top. On this terrace are the ruins of a number of colossal buildings, all constructed of a dark gray stone, often polished to the consistency of marble, from the adjacent mountain. The stones, of great size, cut with the utmost precision, were laid without mortar, and many of them are still *in situ*. Especially striking are the huge columns, 13 of which still stand in Darius the Great's audience hall, known as the apadana, the name given to a similar hall built by Darius at Susa (there are two more columns in the propylaeum or entrance hall of his son, Xerxes).

These ruins, for which the name "Sad-Sutun" ("the 100 Columns") can be traced back to the 4th century A.D., are now known as Takht-e Jamshid ("the Throne of Jamshid," a mythical Persian hero). That they represent the Persepolis captured and partly destroyed by Alexander the Great in 330 B.C. has been beyond dispute at least since the time (early 17th century) of the Italian traveler Pietro della Valle. It was not wholly deserted, for in the Apocrypha (II Macc. ix, 2) it is stated that the Seleucid king Antiochus IV (Epiphanes) during an incursion into Persia was repelled by the inhabitants of Persepolis shortly before his death (163 B.C.). In 1933 two sets of gold and silver plates recording in the three forms of cuneiform, Ancient Persian, Elamite and Babylonian, the boundaries of the Persian empire were discovered in the foundations of Darius' hall of audience. A number of inscriptions, cut in stone, of Darius I, Xerxes I and Artaxerxes III indicate to which monarch the various buildings are to be at-

tributed. The oldest of these on the south retaining wall gives Darius' famous prayer for his people: "God protect this country from foe, famine and falsehood." There are numerous reliefs of Persian, Median and Elamite officials, and 23 scenes separated by cypress trees depict representatives from the remote parts of the empire who, led by a Persian or a Mede, make appropriate offerings to the king at the national festival of the vernal equinox.

Behind Takht-e Jamshid are three sepulchres hewn out of the mountainside, the façades, of which one is incomplete, being richly ornamented with reliefs. About 8 mi. N.N.E., on the opposite side of the Pulvar, rises a perpendicular wall of rock, in which four similar tombs are cut, at a considerable height from the bottom of the valley. This place is called Naksh-e Rostam ("the Picture of Rostam") from the Sasanian carvings below the tombs, which were thought to represent the mythical hero Rostam. That the occupants of these seven tombs were kings might be inferred from the sculptures, and one of those at Naksh-e Rostam is expressly declared in its inscriptions to be the tomb of Darius I Hystaspes, concerning whom Ctesias relates that his grave was in a cliff face and could be reached only by means of an apparatus of ropes. Ctesias mentions further, with regard to a number of Persian kings, either that their remains were brought "to the Persians," or that they died in Persia. It is certain that Cyrus was buried at Pasargadae (*q.v.*), and if there is any truth in the statement that the body of Cambyses was brought home "to the Persians" it might be assumed that his burying place would be near that of his father. A rectangular ruin, however, containing several massive layers of stone of proportions identical with those forming the base of the tomb of Cyrus at Pasargadae, and taken from the same quarry, exists at Takht-e Gohar on the Pulvar, and may have been intended to serve as the tomb of Cambyses.

In order to identify the graves of Persepolis it should be borne in mind that it was the custom for a king to prepare his own tomb in his lifetime. This was certainly so in the case of Darius I, who in an inscription beside the entrance to his tomb describes his own character and states that God had given him two special qualities, namely wisdom and activity. The three other tombs at Naksh-e Rostam, besides that of Darius I, are probably those of Xerxes I, Artaxerxes I and Darius II. Xerxes II, who preceded Darius II, reigned for a very short time and could not have obtained so splendid a monument, still less could Sogdianus (Secydianus), who usurped his brother's throne and reigned for less than a year. The two completed graves behind Takht-e Jamshid would then belong to Artaxerxes II and Artaxerxes III. The unfinished one might be that of Arses, who reigned at the longest two years, but is more likely to be that of Darius III (Codomannus), who is one of those whose bodies are said to have been brought "to the Persians" (Arrian, *Anabasis*, iii, 22, 1).

Since Cyrus was buried in Pasargadae, which moreover is mentioned in Ctesias as his own city, and since, to judge from the inscriptions, the buildings of Persepolis commenced with Darius I, it was probably under this king, with whom the sceptre passed to a new branch of the royal house, that Persepolis became the capital of Persia proper. As a residence for the rulers of the empire, a remote place in a difficult alpine region was far from convenient, and the real capitals were Susa, Babylon and Ecbatana, Persepolis being visited mainly in the spring season. This accounts for the fact that the Greeks were not acquainted with the city until it was taken and plundered by Alexander the Great.

In 316 B.C. Persepolis was still the capital of Persis as a province of the great Macedonian empire. The city gradually declined during and after the Seleucid period, but the ruins remained as a witness to its ancient glory. It is probable that the principal town of the country, or at least of the district, was always in this neighbourhood. About A.D. 200 the city of Istakhr (Estakr, Stakr) was the seat of local governors. There the foundations of the second great Persian empire were laid, and Istakhr acquired special importance as the centre of priestly wisdom and orthodoxy. But from the stone ruins which still stand a few miles northwest of Persepolis, it is clear that Istakhr dates from Achaemenian times. The Sasanian kings (3rd–7th century A.D.) covered the face of the rocks in this neighbourhood, and in part even the Achaemenian ruins, with their sculptures and inscriptions in Pahlavi, and must themselves have built largely here, although never on the same scale of magnificence as their ancient predecessors. The Romans knew as little about Istakhr as the Greeks had about Persepolis, in spite of the fact that for 400 years the Sasanians maintained relations, friendly or hostile, with the Roman empire.

At the time of the Arab conquest Istakhr offered a desperate resistance. The city was still a place of considerable importance in the first century of Islam, although its greatness was soon to be eclipsed by the new metropolis Shiraz. In the 10th century A.D. it had become an insignificant place, as may be seen from the description of the Arab geographer al-Maqdisi (*c.* 985). In the mid-11th century it was razed by the Seljuk amir Qutulmish and its population was transferred to Shiraz. This fruitful region was covered with villages until the frightful earthquakes of the 19th century, and even in modern times it is, comparatively speaking, well cultivated. The "castle of Istakhr" played a conspicuous part as a strong fortress several times during the period of Arab ascendancy. It was the middlemost and the highest of the three steep crags which rise from the valley of the Kor, at some distance west or northwest of Naksh-e Rostam. *See* PERSIAN HISTORY; *see* also references under "Persepolis" in the Index.

PERSEUS (*c.* 212–*c.* 165 B.C.), the last king of Macedonia (179–168), whose imperialist ambitions in Greece brought him into conflict with the Romans. He was the elder son of Philip V, probably by Polycrateia of Argos; insinuations of spurious or slave birth deserve no credence. While still young he commanded troops in his father's wars against Rome (199) and Aetolia (189). From 184 onward he intrigued against his brother Demetrius, representing him as coveting the succession through Roman favour, and in 181 persuaded Philip to execute him; the tradition concerning this is distorted in Polybius' pro-Demetrian account.

On succeeding (179) Perseus renewed his treaty with Rome and recalled debtors and exiles to Macedonia. He extended his influence in Thrace and Illyria, but made special efforts to win over the Greek world. He married Laodice, daughter of Seleucus IV, and gave his sister to Prusias II of Bithynia; he established excellent relations with Rhodes and resumed control of the Delphic amphictyony. In Aetolia and Thessaly, however, he encouraged the revolutionary party, and after subduing a revolt in Dolopia created widespread alarm by visiting Delphi with his army; an attempt to re-establish his influence in Achaea failed, but he made a treaty with Boeotia (perhaps 174). In alarm Eumenes II of Pergamum visited Rome (172) and by his incitement precipitated the Third Macedonian War (171–168). Helped by ineffective Roman strategy, Perseus during three campaigns held his enemy on his southern frontiers near Mt. Olympus; but in 168 niggardliness lost him the support of Genthius of Illyria, thus exposing his western flank, and a reinforced Roman army forced him to fight at Pydna. There his phalanx broke before the more flexible cohorts (*see* PYDNA, BATTLE OF), and Lucius Aemilius Paulus was victorious. Perseus was captured on the island of Samothrace and walked in Paulus' triumph (167). He died at Alba Fucens two years later.

Perseus' character was not unattractive, and alike as administrator, general and diplomatist he stands high. That he planned war with Rome is unlikely, though war was the logical outcome of his policy. His failure revealed his inability to reconcile the needs of Macedonia with the reality of Roman predominance.

PERSEUS, in Greek mythology, the slayer of the Gorgon Medusa and the rescuer of Andromeda from a sea monster. The son of Danaë (*q.v.*) and Zeus, as an infant he was cast into the sea in a box with his mother by her father, Acrisius, king of Argos, to whom it had been prophesied that he would be killed by his grandson. After Perseus had grown up on the island of Seriphus, where the box had grounded, Polydectes, king of Seriphus, desired Danaë, and to rid himself of Perseus tricked him into promising to obtain the head of Medusa, the only mortal among the Gorgons (*see* GORGON). The story of his accomplishment of this task contains a series of folktale motifs.

Aided by Hermes and Athena, Perseus went to the end of the

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

earth to obtain the help of the Graeae, sisters of the Gorgons. They were three hags who shared the use of one eye and one tooth which Perseus seized from them and would not return until they provided him with winged sandals (which enabled him to fly), the helmet of Hades (which conferred invisibility), a curved sword to decapitate Medusa and a bag in which to conceal the head. (According to another version, the Graeae merely directed Perseus to the nymphs of the north, who told him where to find the Gorgons and gave him the bag, sandals and helmet; Hermes gave him the sword, or sickle.) Armed with these, and with a shield from Athena, he set off on his task. Since the gaze of Medusa turned all who looked at her to stone, Perseus guided himself by her reflection in his shield and beheaded her as she slept. Safe from pursuit by her sisters because of his magic helmet, he returned to Seriphus and rescued his mother by turning Polydectes and his supporters to stone at the sight of Medusa's head.

A further legend inserted into Perseus' travels is that of his rescue of the Ethiopian princess Andromeda, when he was on his way home with Medusa's head. Andromeda's mother, Cassiopeia, had claimed to be more beautiful than the Nereids, so Poseidon had punished Ethiopia by flooding it and plaguing it with a sea monster. Andromeda's father, King Cepheus, had been informed by the oracle of Zeus Ammam that these ills would cease if he exposed Andromeda to the monster. Perseus, passing by on his winged sandals, saw her chained to a rock on the seashore awaiting the monster, and fell in love with her. After obtaining Cepheus' permission to marry her if he killed the monster, Perseus turned it to stone by showing it Medusa's head. This legend appears to be a fairy tale from the middle east. The rescue from the monster, which according to some early authorities took place at Joppa, near Lydda, may have been a source for the much later legend of St. George and the dragon.

After taking Andromeda to Seriphus and disposing of Polydectes, Perseus gave the Gorgon's head to Athena, who placed it on her shield, or aegis, and his other accoutrements to Hermes. He then took his mother back to her native Argos, where he accidentally struck Acrisius dead when throwing the discus, thus fulfilling the prophecy that he would kill his grandfather. He consequently gave up the kingship of Argos and founded Mycenae as his capital, becoming the ancestor of the Perseids, among whom was Heracles.

Perseus bearing the Gorgon's head or rescuing Andromeda was a favourite subject in painting and sculpture both ancient and Renaissance. Freud reinterpreted the Gorgon's head in terms of castration, and the English novelist Iris Murdoch used it for modern symbolism in *A Severed Head* (1961).

The chief characters in the Perseus legend, Perseus, Cepheus, Cassiopeia, Andromeda and the monster (Cetus), all figure in the night sky as constellations.

PERSEUS, in astronomy, a constellation of the northern hemisphere, named after the Greek legendary hero. It contains a double cluster forming an interesting object for low-power telescopes. The second brightest star in the constellation is the famous eclipsing variable Algol (*q.v.*). A number of naked-eye stars—of which α Persei is the brightest—make up a loose cluster, which is located at a distance of about 400 light years from the sun. The double cluster itself is much more remote; its distance is of the order of 7,000 light years. The radiant, or apparent centre, of the Perseid meteor shower lies in Perseus.

PERSHING, JOHN JOSEPH (1860–1948), U.S. army officer, commander in chief of American troops in Europe during World War I, was born in Laclede, Mo., on Sept. 13, 1860. After graduation from the U.S. Military Academy at West Point, N.Y., in 1886 he participated in several Indian wars. In 1891 he became instructor in military science at the University of Nebraska, Lincoln, and later taught tactics at West Point. The Spanish-American War gave Pershing an opportunity for rapid promotion. He served with distinction in Cuba and then campaigned in the Philippines against the Moros of Mindanao. While a military attaché in Japan in 1905 he observed the Russo-Japanese War in Manchuria. Pres. Theodore Roosevelt recognized his distinguished service by promoting him to the rank of brigadier general in 1906, passing over 862 senior officers. Pershing served in the Philippines until 1913. He next gained attention as commander of the punitive expedition sent against the Mexican revolutionary Pancho Villa, who raided Columbus, N.M., in 1916.

After the United States declared war on Germany in March 1917, President Wilson selected Pershing to command the American Expeditionary Force (AEF). Pershing went to Europe in June and soon submitted a "General Organization Report" recommending an army of 1,000,000 men by 1918 and 3,000,000 by 1919. Early American planning had not contemplated a large army. The Allies had asked for financial, economic, and naval assistance, assuming the AEF could not be organized in time to provide assistance, but Pershing's recommendations prevailed, especially after Allied fortunes worsened during 1917. By early 1918 American plans called for concentrating an independent army on the western front. Pershing hoped it would spearhead a decisive offensive against Germany.

The exhaustion of the Allies, stemming from the setbacks of 1917, increased Allied dependence on U.S. arms. It also engendered pressure on Pershing to condone "amalgamation" of American troops by small units into European armies. The Allies wanted replacements for their depleted formations to resist expected attacks. Pershing adamantly opposed amalgamation and received support from his government, although he temporarily released his troops to the interallied commander, Ferdinand Foch, during the German offensives of March–June 1918. Pershing also opposed proposals to divert some U.S. troops to secondary theatres. The Supreme War Council, an interallied institution established to coordinate the political-military strategy of the Allies, continually recommended amalgamation and diversionary operations elsewhere than in France, but Pershing remained unmoved. These pressures subsided when the Allies assumed the offensive during the summer.

Pershing's army never became self-sufficient, but it conducted two significant operations. In September 1918 the U.S. forces as-

saulted the Saint-Mihiel salient successfully. Then, at Foch's request, Pershing quickly regrouped his forces for the Meuse-Argonne offensive, although he had originally planned an advance toward Metz. Incomplete preparations and inexperience slowed the Meuse-Argonne operations, but the interallied offensive in France destroyed German resistance and precipitated the Armistice of November. Pershing made some operational and logistical errors, but the creation of the AEF was a remarkable achievement.

Pershing returned to the United States with a great reputation and in 1919 received the rank of general of the armies, a title created in 1799 for George Washington but never held by him. Pershing's stern bearing and rigid discipline earned him the nickname "Black Jack." His determination and dedication gained him respect and admiration if not affection. Eschewing politics, Pershing remained in the Army and was appointed chief of staff, July 1, 1921. He held that post until his retirement in 1924. In 1931 he published a two-volume memoir, *My Experiences in the World War*. Pershing died on July 15, 1948, and was buried in Arlington National Cemetery. (D. F. Tr.)

PERSIA, the name used for centuries, mostly in European and other Western countries, for the kingdom of Iran in southwest Asia. It originates from a geographical region in southern Iran, adjoining the Persian Gulf, formerly known as Persis (*q.v.*) (Pars, Parsa; modern Fars). It was during the rule of the Persian Achaemenid dynasty that the ancient Greeks first came into contact with the inhabitants of Pars on the Iranian plateau. The name was gradually extended beyond the province of Pars to the entire kingdom which became known as the Persian Empire. Throughout their history the people of Iran have never used the name "Persia" for their homeland. They have always called it "Iran" (the land of the Aryans).

On March 21, 1935, the government of Iran officially requested other governments to adopt and use the name "Iran" instead of "Persia." However, as the name "Persia" was widely used by historians outside Iran and the country was better known under that name, in October 1949 the government of Iran announced that it would no longer insist on the use of "Iran" instead of "Persia."

For the ethnography of ancient Iran and an account of Persian history *see* Persian History. The geography, people, archaeology, administration, social conditions, and economy of the modern state are treated under Iran. (M. H. Ga.)

PERSIAN ART. Pictorial art flourished in Persia before Islam, for although no traces of frescoes or illuminations have come down to posterity from the Sasanian period (*c.* A.D. 224–651), it is known from other evidence that that great age of Iranian culture included painting among its many creative activities. Ernst Herzfeld traced to Sasanian models the motifs (dancing girls, huntresses, animal figures, floral decorations of various kinds) of the fragments of ornamental wall paintings which came to light in the course of excavations made at the caliph's palace at Samarra (9th century). At about the same time illumination must have come into favour at Baghdad, probably through the Manichees. Some knowledge of their book painting was gained through the discoveries made by Sir A. Stein and by the German expeditions to Turfan.

PAINTING AND CALLIGRAPHY

The Persian contribution to painting and calligraphy began in the Muslim era, and the form in which it first appeared was that of book production. The share of Persia in the development of this art in the Islamic countries dates from before the beginning of the Abbasid period (750). Toward the end of the 7th century in the two oldest centres of culture in Iraq—Basra and Kufa—beautiful Koran manuscripts in Kufic executed on parchment were common, though at first they had no extraneous decoration, but produced their effect solely by the heavy lapidary style of the archaic character. In the 8th and 9th centuries this branch of Islamic art reached its first period of splendour under the powerful stimulus imparted by the caliphs of Baghdad; and the masters of the Kufic who flourished at that time (*c.* 800) include not only a number of Arabs, but also the Persian Khoshnam of Basra. More important, however, was the part played by calligraphers of Iranian origin in the development of the various forms of the *naskhi*, the round correspondence character, which early began to take a dominant place beside the vertical script. The inventor of the decorative *thuluth*, which derived from this, is said to have been Ibrahim Segzi of Sijistan, and his pupil Ustad Ahwal Segzi has the reputation of having been the first, under the caliph al-Ma'mun, to elaborate and discuss rules of calligraphy. He in turn was the teacher of the celebrated Ibn Muqla, who brought the *naskhi* into general use in place of the Kufic and is regarded as the greatest authority on all the principles of the art. Ibn Muqla's school produced, among other famous pupils, Ibn al-Bawwab, Hasan al-Sirafi (d. 979), who was of Mazdaic origin, and the Buyid prince Fana-Khusru (d. 982), reputed to be a descendant of the Sasanian kings.

The Baghdad School.—The first extant works of the Baghdad school of painting date only from the 12th century, when the Seljuk period had already begun, but in their content and their artistic tendencies they go back unmistakably to older traditions, and continue with little change until the middle of the 13th century. They include scientific treatises (by Dioscorides, Galen and others) translated from the Greek by Nestorian scholars or based on ancient models, with explanatory illustrations; Arabic versions of the Bidpai fables (*Kalila* va Dimna) *wa-Dimna* which were imported from India; and the anecdotes of al-Hariri, then in great favour, in which the bold jests and witty conceits of Abu Sa'id of Serruj were illustrated. These three types of text were all equally well adapted to direct the artist to the study of nature and to emphasize the importance of problems of composition and colour, and the works of this school are veritably astonishing in their wealth of colour shading and their forcible depiction of their subjects. To what extent Persian masters are represented is not exactly known; but the circumstance that the *minai* pottery of Ray (Rhages) (*c.* 1200) borrowed the Baghdad style of painting suggests that the whole tendency had already spread from Mesopotamia to centres in Iran.

As early as about the 10th century, paper had supplanted parchment, not only in secular works but also in copies of the Koran and other religious texts, its manufacture having gradually spread from Samarkand to all the countries of Islam. Ornamental decoration of manuscripts, from which for religious reasons figures were excluded, also made continual strides, and soon the craft of the illuminators and gilders began to break away from that of the calligraphers and painters and to develop on its own lines. Kufic was now no longer used except in chapter headings and title pages; elsewhere the script employed was either one of the many variants of *naskhi*, or a decorative script representing a more graceful and stylistic development of the vertical character.

The Il-khan Period.—The Mongol invasion in the 13th century proved unexpectedly fortunate for the art of book production in western Asia. Hulagu and his successors not only took pains to promote it in every possible way, but also brought it into contact with the highly developed painting of the far east, and directed it toward new subjects, with the important effect of immensely enlarging the painters' outlook. The main tendency was now to the pictorial representation of historic events and legendary episodes, in world histories conceived on a large scale like Rashid al-din Fadlullah's and the principal result of acquaintance with the works of the Chinese masters of the Sung period was to enhance the feeling for landscape. In manuscripts of the early 14th century the strong foreign stimuli are seen combining with older traditions, and in course of time there developed a new Persian-Mongol style of painting which reached a high standard in the two capitals of the Il-khans, Baghdad and Tabriz. The profane texts were now no longer in Arabic, but generally in Persian, and the whole art of miniature painting was soon iranized when the great national epic of Firdausi and other poems, such as those of Nizami and Khwadju Kirmani, became increasingly common in illustrated and often sumptuous copies. New and effective uses were found for devices of composition, and, moreover, the arrangement of the verses in vertical columns, which could be broken up wherever desired, made possible a much more intimate and aesthetically satisfying conjunction of picture and text than had been known previously. Heroic

scenes from the *Shah-Nama*, sentimental themes from *Khosrau and Shirin, Laila and Majnun*, etc., were then for the first time expressed in characteristic forms.

Of Arabic texts there were at this period mainly the cosmography of Qazwini and a few astronomical treatises, which seem to have been produced with loving care in western Turkistan. To the Baghdad school of calligraphy belongs the credit of developing, about 1300, the lapidary style of the Kufic Korans into the round writing, and bringing this to the ripest degree of ornamental beauty in majestic variants. In the production of the magnificent Korans of the age of the Il-khans, with their large size and their few and incomparably imposing lines of script in black and gold, Persian masters were primarily concerned; and they carried to Tabriz and Samarkand the new principles for the decoration of the holy book, especially the rich arabesque illumination.

The Timurid Schools.—When Timur altered the whole political complexion of western Asia, a highly productive centre arose at his capital of Samarkand. His chief secretary, Amir Mohammed Badr ud-din, gained a reputation as a master of all forms of writing, and two of the great emperor's grandsons, Ibrahim Mirza and Baisonqur Mirza, were famous calligraphers. At Timur's court there came into favour, through the stimulus of far eastern models, the separate sheet bearing a light ink sketch, sometimes with some touches in gold and colour, to be pasted on cardboard and collected in albums. The traditional miniature illustration in body colour found in this period a new and prosperous evolution in the schools of Herat and Shiraz.

Baisonqur Mirza, who unfortunately met with an early death in 1434, earned much honour by founding at Herat an academy in connection with his library; for years it employed 40 calligraphers, besides numerous illuminators and painters. In this academy the Persian texts were no longer written in *naskhi*, but in *nastaliq*, an offshoot of the old cursive character, invented by the celebrated Mir Ali of Tabriz. All the 40 masters of Herat were directly or indirectly his pupils, and toward the end of the century the style of calligraphy invented by him found its most splendid representative in Sultan Ali of Meshed (d. 1513), the protégé of the famous poet and minister Mir Ali Shir Newai and friend of the great poet, Jami.

The preference that painters displayed for subjects drawn from the national literature, and the enthusiasm with which they steeped themselves in the magic of their native countryside, give to Persian painting of this period a romantic note which often chimes with the atmospheres found in contemporary western Gothic. In the east, however, the purely decorative and impersonal character of the pictures continued, and Shiraz rivaled with Herat in the same line, but using a colour scheme of its own.

It was at this time that the harmony between picture and text reached the highest imaginable degree of perfection, and the leaves of the extant manuscripts are astonishing in the skill with which the painters fitted their subjects into spaces allotted to them quite arbitrarily by the calligraphers. Meanwhile at the beginning of the 14th century the backgrounds were still carefully coloured red or yellow; subsequently a rich blue became general, and it was not until the end of the period that a gold background came into favour. The incidental landscape is generally of a steppelike character; jagged rocks, isolated trees, and little brooks rippling among stones and bordered by growing flowers, are the essential features of almost all open-air scenes, and only occasionally is the mysterious atmosphere of the forest or the luxuriance of a flower garden depicted. The highly effective motif of a tree in blossom, which is often used in smaller pictures, is obviously taken from Chinese models of the Ming period. Under the Timurids direct contact with the far east became increasingly frequent.

Behzad of Herat.—An undeniable weakness of Timurid painting lies in the diagrammatical conventionalizing of the figures, the spiritless treatment of the heads, and the absence of expression in the movements. In this respect no progress can be seen throughout the whole development of the art, which in other directions is so astonishing; and the appearance of a completely revolutionary personality was needed before a change could be brought about and new paths indicated. This personality was found in the genius Behzad of Herat, who is rightly honoured as the greatest master of Persian painting. Behzad understood how, even in his most populous compositions, to differentiate every single figure in countenance and bearing; his palette was extraordinarily rich, especially in warm, full tones, and this enabled him to individualize his portraits by the employment of numerous colour nuances for costumes and even for flesh. He was also a reformer in the treatment of landscape, which appears more naturalistic in his pages than in those of his forerunners, and in the choice of subject a markedly realistic note is likewise seen. Moreover, it was he who revolted against the dictation of the calligraphers, and admitted no text at all, or only a few lines of verse in one corner, in the pages he illustrated; even a number of double-page miniatures by his masterly hand can be seen.

Behzad, who was born before 1450 and died after 1520, represents the zenith of the Timurid and the opening of the Safavid period in Persian painting. He was head of the Herat academy until 1506, when Shah Ismail took him to Tabriz, made him his chief librarian, and covered him with honours. Only a few extant works are indisputably by his hand. Both in Herat and in Tabriz he had many pupils, who carried his style far and wide in Persia, western Turkestan and India; and even in the 16th century his name was already so famous that his art was imitated on every side, while later on pages of the most various origins were furnished with his signature to enhance their value.

The Tabriz School.—The next generation of painters in Tabriz is dominated by the highly gifted Sultan Mohammed, who exercised a commanding influence in the whole field of art at the court of Shah Tahmasp. In collaboration with other masters he illustrated de luxe editions of the Persian epics, several of which have come down to posterity; but for the most part he preferred genre subjects and portraits, which were produced as single sheets and were designed to be bound in volumes together with specimens of the handwriting of famous calligraphers. He opened new fields of activity to the painters by bringing lacquer bindings into fashion, and also by inducing them to design patterns for textiles and knotted carpets to be made at the royal factories. Some of the studies for the celebrated hunting and animal rugs of the 16th century were made in his studio, as were also a few velvets and silk brocades with figure subjects.

From the end of the 15th century an immense impetus had been given to Koran decoration at Tabriz. It was here that the picturesque division of the title pages into star- or medallion-shaped fields and borders with a reciprocal pattern or a cartouche design was devised, and this again brought about a revolution in the style of Persian carpetmaking. The ornament grew richer and more complicated; to the arabesque were added slender floral twines in a profusion of lines, palmettes, rosettes and cloud patterns.

In Behzad's time Shah Mahmud of Nishapur came to eminence as a master of the *taliq* script and later Mir Ali of Tabriz, "the royal scribe" (d. 1559). Many other calligraphers and illuminators heard the call of the Ottoman rulers and founded a school of book decoration at Constantinople, which adhered closely to the tradition of Tabriz; they were accompanied by painters like Shah Quli and Wali Jan.

The Isfahan School.—Late in the 16th century, when all the artistic forces of Persia were once more being concentrated at the new capital, Isfahan, under the powerful impulse communicated by Shah Abbas the Great, there arose also in Isfahan a new and important centre for the art of book production in all its various forms. Mir Imad al-Husni (d. 1618) and Riza 'Abbasi competed in calligraphy for the royal favour, while others sought to attract attention by animal figures ingeniously constructed out of pious mottoes and similar jests, or by a perfect mastery of the *shikasta*, a complicated script so full of flourishes as to verge on illegibility. In painting there is a link with the schools of Herat and Tabriz in the person of Ustad Mohammedi, who was undoubtedly the first to put his observations of nature on to paper in the purest ink-wash technique without any reference to a text. His successor as head of the painters' guild at Isfahan was Riza 'Abbasi, whose signature, genuine or doubtful, is frequently met with; it is still not

established beyond dispute whether this artist is identical with Aga Riza, who is thought to be of an older generation. Be that as it may, it was he who filled the albums of Persian and Indian collectors with his gay, sure-handed colour sketches and drawings in red chalk on the most everyday subjects, and with carefully executed pages in rich colour; and he ultimately became so much admired as almost to overshadow, for a time, the fame of Behzad. He likewise gave a new impulse to the illustration of manuscripts, and his elegant, fashionable style gained him a great influence in the other decorative arts also; wall paintings, figural tiles and lacquered doors in the garden palaces of Isfahan clearly show the mark of his atelier. Riza's best pupil, and his bosom friend, was Mu'in, one of whose extant works is a portrait of his master. The style created by the latter was still a living force at the end of the 17th century, when Shah Abbas II's effort for an assimilation to European painting had already failed, as is shown by the fact that of the young artists he sent to Rome only Mohammed Zaman gained some reputation.

In the 18th century European paintings and engravings were slavishly copied, and Nadir Shah's expeditions to India introduced transitory influences of the Mogul school. At the beginning of the 19th century an enormous impetus was given to lacquer painting, though only as an ordinary bazaar industry, and decoration also took the form of large canvases. Since the end of the 19th century the growing interest for Persian miniatures has called into existence a considerable number of workshops for the production of fakes, where single pages and even complete manuscripts are concocted in the style of any old master or period. This somewhat questionable development has at least the advantage of maintaining some contact with the masterpieces of the past. (E. K.)

ARCHITECTURE, CERAMICS, TEXTILES, METALWORK

As with painting and calligraphy, a certain strain of decorative skill dating from the Islamic conquest permeates all other forms of Islamic art generally known as Persian, but pre-Islamic influences are not absent, and such Sasanian motives as twinned animals facing each other appear constantly.

Architecture.—In architecture, the love of barrel-vaulted porches can be traced directly to Sasanian palaces and were the chief motives of the great mosques where they were flanked by twin minarets in the design of which appears that emphasis on height which is universally Persian. A second characteristic was the use of a dome with two shells, the outer onion-shaped and supported on a high drum, and the swelling slight in early examples but more pronounced later. Daring ingenuity of construction marks all these vaults and domes. The stalactite (*see* STALACTITE WORK) corbels, elaborate intersections of curved surfaces, delicate groined lines and scalloped forms display great skill and differ widely from similar Islamic buildings elsewhere.

The progress of architecture from the Seljuk domination continues to a rich climax in the 16th and 17th centuries.

During the 18th century there developed rich and delicate wooden construction including slim columns, intricate cornices treated with lavish carving and inlays used frequently in the exquisite formal gardens so important to Persian life. The Muslim love of surface ornament led to dominance of plane surfaces covered with tiles so that walls, vaults, domes and minarets glowed with blue-greens and turquoise, rose and yellow. In no other style has applied colour become such an integral part of architectural design. (*See* ISLAMIC ARCHITECTURE; TILE.)

Ceramics.—Springing from the most ancient Mesopotamian development of pottery Persian ceramics developed in about the 13th century into one of the most exquisite of all arts. The pottery body was coarse because of the available clay but the glazes were developed to a high degree of perfection and the coloration, especially the blues ranging from turquoise to cobalt, became world famous. Sasanian, Parthian and Byzantine influences lent vigour and charm. By the 14th century floral ornament became more important and the designs were freer and less formal. Vases were decorated in low relief and covered with monochrome blue glaze. During the 16th century the Chinese influence made itself felt and became strong in the 17th century not only in design but in methods of manufacture and at the same time Persian influences were felt in China. Tiles were of course an important phase of the ceramic industry. (*See* POTTERY AND PORCELAIN: *Islamic Pottery;* MOSAIC.)

Textiles.—Church treasuries throughout Europe reserve textiles that are obviously of Asiatic origin showing the same Sasanian and Byzantine influences felt in Persian ceramics. Lions, eagles and imaginary beasts enclosed in geometric patterns form the decoration on a material of woven silk and sometimes gold and silver. Prior to the 13th century these textiles came from different parts of the Islamic world but later from Turkey and Persia, the Turkish development appearing in conventionalized ornament and the Persian from the 18th century onward showing greater complexity in formality and realism, and influenced eventually by Chinese elements as a result of the Mongol domination.

Rugs are the most important of Persian textiles, the best of them, which date from the 16th and 17th centuries, displaying amazing delicacy in technique and great decorative skill in design with rich soft colours marvelously adapted to the texture. (*See* EMBROIDERY; TEXTILES; RUG AND CARPET; BROCADE.)

Metalwork.—The Persians were aesthetic craftsmen in metal and their delicate inlaying of silver and gold into copper and steel of intricate geometric and naturalistic ornament shows decorative genius and the greatest of technical facility. The motives in this work were similar to those used in ceramics and textiles.

A rinceau or branching scroll ornamented with sharp pointed spearlike leaves was widely used. Much of this artistry was employed, of course, in the decoration of arms and armour and although there is a definite resemblance between the work of Turkey and Persia, the Persian far surpasses with its richness and delicacy. *See* IRAN: *Archaeology;* METALWORK, DECORATIVE; SILVER AND GOLD WORK; *see* also references under "Persian Art" in the Index. PERSIAN GULF extends southeastward for about 500 mi. (805 km.) from the mouth of the Shatt al Arab to the Musandam peninsula and varies in width from 140 mi. (225 km.) at the head to 220 mi. (354 km.) at its widest part. However, "the Gulf" is a term frequently used to refer not only to the Persian Gulf proper but also to its outlets, the 50-mi. (80 km.) wide Strait of Hormuz and the Gulf of Oman, which opens into the Arabian Sea. In the Persian Gulf the depth of water rarely exceeds 50 fathoms and increases more rapidly from the Iranian than from the Arabian shore. Off the Arabian coast there are large areas of water less than 20 fathoms deep where valuable pearl banks occur.

There are nine political units with shorelines on the gulf. Iran occupies the entire northeastern shore and the head east of the Shatt al Arab. Iraq has a 40-mi. (64 km.) wide frontage west of that river. The Arabian side is divided among Kuwait (Al Kuwayt), the Neutral Zone, the kingdom of Saudi Arabia, the sheikhdom of Bahrain, the sheikhdom of Qatar, the seven sheikhdoms of Trucial Oman, and the Sultanate of Muscat and Oman.

PHYSICAL GEOGRAPHY

Coasts.—The coasts of the Persian Gulf have a total length of nearly 2,000 mi. (3,219 km.) and there are important contrasts between the Iranian and Arabian sides. On the Iranian side, moun-

TOPOGRAPHY OF THE COUNTRIES SURROUNDING THE PERSIAN GULF. DERRICKS INDICATE MAJOR OIL-PRODUCING AREAS

tain ranges which make up the edge of the Iranian plateau run parallel to and at no great distance from the shore so that the land rises abruptly from a narrow coastal plain. On the Arabian side, the rise is much more gentle and there are broad lowlands between the Gulf and the interior plateau.

The Iranian coast extends southwestward from the Strait of Hormuz to Lengeh, cutting across the southeastern ends of a number of parallel mountain chains. The large island of Qeshm (Qishm), 67 mi. (108 km.) long, is separated from the mainland by the Clarence Strait (Khuran). The mainland coast is an alternation of cliffs and alluvial lowlands. The latter represent the deltas of small rivers descending from the mountains and contain mangrove swamps. Beyond Lengeh the coast turns northwestward parallel to the mountain ranges. The coastal plain is narrow except where valleys open out into areas of swamp, marsh, and mud flat. North of Bushire (Bushehr) the plain is much wider and the coasts low and sandy.

The head of the Gulf is a deltaic area fed by the only major rivers which flow into it. The Shatt al Arab (the lower course of the combined Tigris and Euphrates), together with the much smaller Karun and Jarrahi rivers, bring down large quantities of silt and extend the land steadily seaward. Thus a zone of swamps, up to 40 mi. (64 km.) wide, characterizes this stretch of coast.

The whole of the Arabian shore is desert, the only water being provided by springs. The desert is stony in the northwest but predominantly sandy in the southeast. Numerous small shifting creeks occur and there are stretches of mangrove swamp and salt marsh, the latter most widespread along the Trucial Coast. Coral reefs lie offshore and there are many small islands. The northern part of the Musandam Peninsula is precipitous and rocky.

Geology.—Structurally the Persian Gulf is a continuation of the Tigris-Euphrates trough, the whole forming a median zone between the fold mountains of southern Iran (the Zagros Mountains) and the stable continental block of the Arabian foreland. Minor folds within this median zone have little effect on surface relief with the exception of the Musandam Peninsula and the southern side of the Gulf of Oman. There, an upfold of Jurassic and Cretaceous rocks, with an igneous core, forms the Jabal al Akhdar, a much-dissected plateau with peaks rising to nearly 10,000 ft. (3,048 m.). This area is a product of mid-Cretaceous earth movement and formed a northward-projecting buttress against the Pliocene folding of the Zagros system. This arrangement accounts for the bowlike, curved form of the Iranian folds on either side of Bandar Abbas and for the narrowness of the Strait of Hormuz. The remainder of the median zone, from the strait to northern Iraq, is deeply infilled with sedimentary materials. Miocene, Pliocene, and Quaternary rocks, for the most part little disturbed, outcrop over wide areas in Mesopotamia and are continuous along most of the Gulf coast. The surface outcrops along the shores are a variety of sandstones, marls, limestones, and gypsum, with occasional exposures of Eocene and Upper Cretaceous limestones. The latter occur in elongated dome structures which form the Qatar Peninsula and the island of Bahrain. The numerous islands of the eastern half of the gulf are developed on intrusive salt plugs. On the Iranian mainland there are many of these features, which in some cases form great salt mountains rising to nearly 4,000 ft. (1,219 m.) above the surrounding plain; *e.g.*, near Borazjan. The salt masses are 4–6 mi. (6.4–9.7 km.) wide and appear as intrusions.

The oil resources of the area occur in the sedimentary rocks of the median zone. Those of southwestern Iran are found in Tertiary rocks which have been strongly folded. The oil fields of southern Iraq and of Arabia, in contrast, are a good deal older geologically, occurring in rocks of Jurassic and Cretaceous age. These lie at considerable depth beneath Tertiary deposits. Folding has been very restricted because of the protective presence of the rigid Arabian foreland so that the structures are broad, gentle anticlines. As a result, surface relief offers no guide to the distribution of oil pockets, a fact which has added to the difficulties of prospecting in the area. Other minerals of less importance are associated with the sedimentary rocks. Gypsum and salt are the most widespread and large quantities of the latter are now exported from the islands. In Oman some poor coal has been found and there is copper in the interior, but neither of these can be considered a major resource.

Climate.—The climate is characterized by high temperatures and low precipitation. In the winter months mean temperatures increase from west to east; in the summer the reverse is the case so that the annual temperature range is somewhat greater at the head of the Gulf than at its outlet. Temperatures below freezing have been recorded on a few occasions at the head of the Gulf in January, and readings above 38° C (100° F) are common throughout the area in summer.

Rainfall is appreciably higher on the Iranian coast than on the Arabian side, mean annual amounts being: Khorramshahr 8.4 in. (213 mm.), Kuwait 4.9 in. (124 mm.), Bushire 10.8 in. (274 mm.), Bahrain 3.2 in. (81 mm.), Jask 4.7 in. (119 mm.). In the Jabal al Akhdar the annual total rises above 20 in. (508 mm.). Throughout the area, most of the rain comes in the winter months in the form of heavy showers. The average number of days of rain varies from 27 at Khorramshahr to 7 along the Arabian shore. Relative humidity is high; values over 80% are common. The prevailing wind is the northwesterly shamal. This occurs as squalls of short duration in the winter but blows regularly in summer and may rise to gale force for several days. The southeasterly *qaus* and the southwesterly *suhaili* are less common but more dangerous, since they blow directly into otherwise sheltered anchorages. In the Gulf of Oman easterly winds are more frequent than in the Persian Gulf and predominate in the summer months. Land and sea breezes are important along these coasts, particularly in spring and autumn when there is a large diurnal temperature range.

Vegetation and Land Use.—Throughout the islands and coastal fringes of the Gulf natural vegetation is sparse. True desert is confined to the Arabian side: the Iranian shores may be classified as semidesert steppe, but over the whole region cultivation is limited to areas where irrigation water is available. Because of its higher rainfall and the rivers descending from the Zagros, the Iranian side is slightly more favoured and numerous agricultural districts exist there; one of the largest is around Bandar Abbas. Along the Arabian coast there are places at which freshwater springs, probably fed from the western highlands of Arabia, emerge and support oases of cultivation. The most productive of these occurs around the periphery of Bahrain Island, much of which is covered with date groves and smaller patches of citrus fruits, cereals, and fodder crops. Similar cultivation on a smaller scale occurs from the coast opposite Bahrain inland to Al Hufuf, around the fringes of the Qatar peninsula and around Sharjah on the Trucial coast. In Kuwait dates, vegetables, and cereals are produced, but the water supply is very limited. A special case is provided by the northern coast of Muscat, where streams and springs from the Jabal al Akhdar provide irrigation water for

a considerable area on the lower slopes. The crops include millet, wheat, barley, fruit, and coffee. Over most of the Arabian coastlands, however, cultivation is impossible and the area is one of pastoral nomadism. Camels are bred extensively, particularly in Oman, and flocks of sheep and goats are kept.

Fish.—About 200 varieties of fish are known, including the seer, mullet, sea bass, members of the horse mackerel family, the Indian shad, several species of sea perch and sea bream, and varieties of the sardine. Sharks, rays, porpoises, and swordfish are common and the narwhal is sometimes seen. The edible fish are mostly caught by trap or stake net and dried fish is an important element in the diet of some areas.

THE ECONOMY

Pearling.—The Great Pearl bank is in the waters of the bight between Sharjah and the north of the Qatar peninsula and south of a line from this point to the island of Abu 'Ali off the Saudi Arabian coast. Small quantities of pearls are also found off the Iranian coast. Although the industry has declined greatly since the introduction of the cultured pearl, it is still of some importance, the pearling fleet being based mainly on the Trucial Coast.

Oil.—The economy of the area has been completely transformed by the discovery and exploitation of oil. This applies particularly to the states on the Arabian side of the Gulf, where oil is the major source of revenue. The Khuzistan fields of southwest Iran, together with those of southern Iraq, may be considered as part of the Persian Gulf oil area. The former occupy a belt along the southwestern flank of the Zagros mountain ranges and are six in number: Lali, Masjed Soleyman, Naft-e Safid, Haft Gel, Agha Jari (Aqa Jari), and Gach Saran. There is also a gas field at Pazanan. The Masjed Soleyman field was opened in 1908 and the remainder at various dates between 1928 and 1938. The six fields together account for about 95% of the total Iranian production. The fields of southern Iraq, in contrast to those in the interior of the country, were discovered later, that at Az Zubayr having been opened in 1949 and that at Rumaylah (Rumaila) in 1953. These two fields, to the southwest of Basra, rapidly increased their production, and in 1960 accounted for about half the Iraqi production. The Iranian and southern Iraqi oil fields were connected by pipeline to the Abadan refinery and to the new oil terminal at Al Faw respectively. Iranian oil is also shipped from Bandar-e Ma'shur and from the new refinery on Khark Island.

Although oil was discovered at a number of points along the Arabian coast in the 1930s, the only field developed on any scale before World War II was that on Bahrain Island. In the postwar period, however, many important discoveries were made and production increased very rapidly. Exploration, including that of submarine resources, continues and output is likely to rise still further. Within the present zone of oil production, stretching about 700 mi. from Kuwait to Trucial Oman, there are about 12 main producing districts.

In Kuwait oil was first discovered in the Al Burqan district in the late 1930s but it was not until after 1945 that the vast potential of this small state was fully recognized. Al Burqan, together with the adjacent Ahmadi field and the Raudhatain field near the Iraq frontier, were connected by pipeline to the refinery and terminal at Mina' al Ahmadi. Kuwait's total output of crude oil in 1963 was 97,197,000 metric tons (709,538,000 bbl.), making that country the world's fourth producer after the United States, Venezuela, and the U.S.S.R. The Wafrah field, in the Neutral Zone, was opened in 1953 and in 1963 produced 16,441,000 metric tons (120,019,300 bbl.). Oil from this source was pumped to the refinery at Mina' Su'ud (Sa'ud), on the zonal coast, and to Mina' 'Abd Allah (-al-Abdullah) in Kuwait.

The Gulf coast of Saudi Arabia contains a number of fields, of which the Al Qarah field is the most important. Strikes made at 'Ayn Dar and Harad in 1948 and at Shadqam and 'Uthmaniyah in 1951 proved to be on a single field covering an area of about 2,000 sq.mi. (5,180 sq.km.). Earlier areas of production are Ad Dammam (opened in 1936), Buqayq (Abqaiq) (1941), and Al Qatif (1945), and later developments took place farther north at Saffaniyah (1951) and Abu Hadriyah-Fadili-Kharsaniya (1956–57). The various fields were linked to refineries and terminals at Ras Tanura (Ra's at Tannurah) and Bahrain. In order to obviate the long sea passage around the Arabian peninsula and through the Suez Canal, Tapline (Trans-Arabian pipeline) was completed in 1950; it linked the Saudi Arabian fields to Sidon on the Lebanese Mediterranean coast. Total production from the Saudi Arabian fields in 1963 was 81,142,000 metric tons (592,336,600 bbl.).

The Bahrain field began production in 1932 and output doubled after World War II. However, reserves there are limited, and production was not expected to rise much above the 1963 level of 2,236,000 metric tons (16,322,800 bbl.). The refinery and terminal on the island handle the entire output.

Qatar contains the large Dukhan field on the west coast, from which crude oil is piped across the peninsula to the Musay'id terminal. The field was opened in 1940 and produced 9,096,000 metric tons (66,440,800 bbl.) in 1963. Production from the Murban field on the Abu Dhabi (Trucial Oman) coast began in 1963, a year after the opening of the large offshore Umm Shaif field. Production from these two sources in 1963 totaled 2,342,000 metric tons (17,096,600 bbl.). The development at Umm Shaif illustrated both the rapidity with which new reserves were being discovered and exploited, and the increasing attention being paid to the underwater fields of the Gulf.

Total output from the Persian Gulf fields, excluding Iran and Iraq, rose from 1,100,000 metric tons (8,030,000 bbl.) in 1938 to 208,454,000 metric tons (1,521,714,200 bbl.) in 1963. The latter figure was somewhat above those of Venezuela (170,000,000 metric tons; 1,241,000,000 bbl.) and the U.S.S.R. (200,000,000 metric tons; 1,460,000,000 bbl.) for the same year and was exceeded only by that of the United States (410,000,000 metric tons; 2,993,000,000 bbl.). Iran as a whole (72,825,000 metric tons; 531,622,500 bbl.) is the world's sixth largest producer, and Iraq (56,669,000 metric tons; 413,683,700 bbl.) the seventh.

Until 1950 control of the oil fields was completely in the hands of European (predominantly British) and U.S. concerns, subject only to royalty agreements with the local authorities. The Iranian fields were run by the Anglo-Iranian Oil Co., and those of Iraq were controlled by the Iraq Petroleum Co. Ltd., a joint British-Dutch-U.S.-French concern. The Kuwait Oil Co. Ltd. was owned jointly by British Petroleum and the U.S. Gulf Oil Corp. In Saudi Arabia the concession was held by Aramco (Arabian American Oil Co.), a consortium of four major U.S. concerns. The American Independent Oil Co. and the Getty Oil Co. (U.S.) held jointly operated concessions in Kuwait, Saudi Arabia, and the Neutral Zone. The Bahrain Petroleum Co. Ltd. was a joint subsidiary of two U.S. concerns and the Qatar field was run by the Iraq Petroleum Co. This situation marked a considerable increase in U.S. interest in the area compared with prewar years.

After 1950 a number of important developments occurred. First, the concessionaires relinquished control of parts of their holdings to the local states. In 1951 the Anglo-Iranian Oil Co. was taken over by the Iranian government and in 1954 agreement was reached between the National Iranian Oil Co. (N.I.O.C.) and a consortium of British, Dutch, French, and U.S. operators whereby the concessions were the property of the N.I.O.C. and profits were divided equally between the national company and the foreign operators. In 1962 the Kuwait Oil Co. Ltd. relinquished to the state of Kuwait its rights over about three-fifths of the territory. Although the area given up contained no proven reserves, it might well eventually become productive.

A second development was the entry into the area of capital from new sources. This trend is represented by Japan's Arabian Oil Co. Ltd., which in the 1960s held the concession for the offshore area of the Neutral Zone. Production on a significant scale began in 1961, the crude oil being shipped to Japan.

The sudden influx of wealth into the area has had a tremendous effect on its economy, particularly in the case of the states of the Arabian peninsula, whose national incomes previously were negligible. That of Saudi Arabia in 1930, for example, was £150,000. In 1960 oil royalties alone amounted to £100,000,000. Much of this wealth, the actual proportion varying greatly from one country to another according to government policies, has gone into economic

development of many kinds. Large numbers of formerly semi-nomadic people have settled down to regular paid employment. The political implications have been numerous. Apart from the increased significance attached to the area by the great powers, increased wealth has enabled the states to adopt a more independent policy. At the same time dissension among them has been increased by their division into oil-rich and oil-poor groups. Since the Middle East as a whole is reputed to contain between 50% and 75% of world petroleum reserves, the significance of the Persian Gulf states is likely to increase still further.

Ports.—No part of the Gulf coast is particularly favourable for port development. Natural harbours are rather more common on the Iranian side, but even they have little shelter from the prevailing wind. Bandar Abbas, on the Strait of Hormuz, and Bushire are connected by road to the interior. Bandar-e Shahpur, however, is the chief port of Iran. Standing at the head of the Gulf, it is connected to the Iranian rail system. Abadan, 40 mi. up the Shatt al Arab, is of more recent origin and owes its existence to the oil traffic. Apart from the oil terminal at Al Faw on the coast, the only other Iraqi port is Basra, on the inland side of the marsh zone.

On the Arabian side ports are of two kinds: the older are small centres of trade, fishing, and pearling; the newer are large oil terminals constructed at points suitable for tanker access. In the first category are Al Manamah (Manama) in Bahrain, Ad Dawhah (Dohah) in Qatar, Dhahran (Az Zahran) and Ad Dammam in Saudi Arabia, and Ash Shariqah (Sharjah) and Dubai (Dubayy) on the Trucial Coast. The new oil terminals are at Mina' al Ahmadi and Mina' 'Abd Allah in Kuwait, Mina' Su'ud in the Neutral Zone, Ras Tanura in Saudi Arabia, Bahrain, and Musay'id in Qatar.

(J. C. De.)

HISTORY

The continuing theme of Persian Gulf history has been its evolution as an area linking East and West, starting from the time when the Sumerians pioneered navigation from Eridu (*q.v.*), then on the sea. About 700 B.C. the Babylonians were trading with India, but history is largely conjectural until the time of Alexander the Great (d. 323 B.C.). Most of it then derives from classical writers. Gerrha (modern Al 'Uqayr on the Gulf of Bahrain) early became an important trading centre.

The Arab conquests brought Islamic rule to all the Gulf countries in the 7th century. In the 9th, Siraf, visited by Chinese vessels, and Basra were the principal ports. During the 14th century Hormuz, with an immense Indian trade, was the chief entrepôt.

European Trading Rivalries.—Early in the 16th century the Portuguese captured world trade supremacy, and control of the Gulf became an important objective in securing the route to the Far East. By 1515 Affonso de Albuquerque had secured Hormuz and closed the Gulf to other shipping. Throughout the 16th century the Portuguese controlled all trade through Hormuz but toward its end Dutch and English adventurers began to compete for spices.

In 1600 the English East India Company was formed, and obtaining a licence from Shah Abbas I of Persia in 1616, started trading at Jask. The Portuguese opposed them, but with reluctant English help the shah took Hormuz in 1622: he had taken Gombrun as a countercheck upon Hormuz and renamed it Bandar Abbas. He allowed the English company to establish a factory there in 1623, but the Dutch, who had formed the Dutch East India Company in 1602, quickly followed and took the lead. In 1639, therefore, the English started trading at Basra under a Turkish licence. A factory was established in 1643. The French East India Company, formed in 1644, started a factory at Bandar Abbas but the Dutch remained predominant until toward the end of the century. With their withdrawal from Basra, Bushire, Bandar Abbas, and Khark (Kharg) Island between 1752 and 1766 Dutch influence ended and chaotic conditions in Persia left the British virtually supreme.

Soon after 1793, Saiyid Sultan bin Ahmed, brother of the ineffective imam of Oman, established himself on the Persian coast and became a new force in the Gulf area. In 1798 the East India Company made an agreement which secured his support and strengthened the English position.

British Influence in the Gulf.—During the 18th century the interests of the English in India ensured their continued concern with the Gulf. In 1698 the English, Dutch, and French had agreed to share responsibility for policing gulf waters, but the whole responsibility gradually passed to the English. The shah's decree in 1763 described the English agent as "Governor-General for the English nation in the Gulf of Persia," and gave the East India Company virtually exclusive liberty of trade. The residency established at Bushire in 1763 was entirely commercial at first but increasingly assumed political control.

In the early 19th century the "pirate coast" of Arabia became the main problem. After expeditions against the headquarters of the dominant seafaring tribe, the Qawasim, at Ras al Khaimah in 1809 and 1819, the sheikhs signed a general treaty of peace in 1820, agreeing to abstain "from plunder and piracy by land and sea" except by way of acknowledged war. Following the Maritime Truce in 1835 the coast was renamed the Trucial Coast. The Perpetual Maritime Truce of 1853 outlawed all sea warfare and gave Britain formal responsibility for enforcement. Great Britain avoided internal commitments though the Wahhabis of Arabia were expelled from the Al Buraymi (Buraimi) Oasis in 1869.

A British agreement with the Trucial sheikhs in 1869 restraining them from relations with other governments alarmed the Turks, who occupied Al Hasa and Dohah on the Qatar peninsula in 1871. Although Britain recognized Turkish influence over Kuwait, the Turks feared British use of the port would lessen Basra's trade, and so exercised some control.

In 1892 Britain signed agreements with the rulers of both the Trucial Coast and Bahrain which placed their territories under British protection. Russian attempts to secure a railway concession linking the Mediterranean with the Persian Gulf (with implications of Russian influence at Kuwait) also caused the British to meet the Sheikh of Kuwait's request for protection and in 1899 a comprehensive treaty was signed. In 1902 the Germans obtained a concession to extend the Anatolian Railway to Baghdad and Basra but an Anglo-Turkish agreement in 1913 gave Britain representation on the board and control of extensions south of Basra. It recognized Kuwait as an autonomous Turkish *kaza* (district), and the validity of Anglo-Kuwait agreements. Turkey abandoned pretensions to sovereignty over Bahrain, Qatar, Muscat, and the Trucial Coast and recognized the British right to police, light, and buoy the Gulf. Turkish limits were defined by a line roughly marking the southern boundary of Najd, including Al Hasa.

In 1913 Ibn Saud's capture of Al Hasa brought the Wahhabis back to the coast. He was warned against interference with Qatar or the Trucial sheikhdoms. Qatar became a British-protected state in 1916 and in the Treaty of Jidda (1927) Ibn Saud agreed "to maintain friendly and peaceful relations" with Great Britain, Kuwait, and Bahrain.

Effects of Oil Discoveries.—The discovery of oil meant a change in the British role, particularly on the Arabian coast. Protection of natural resources from hostile powers required direct concern with landward boundaries, and defense of the protected states became more important. In 1914 World War I forced Great Britain to occupy Basra to protect the oil fields and the Abadan refinery. The disappearance of the Turkish Empire meant the emergence of Iraq, under British mandate until 1932. The British resident at Bushire, responsible to the government of India, had much influence on the Persian coast until the Persian military leader Reza Khan consolidated his position. In 1935 the naval base was removed to Bahrain. After Reza Shah Pahlavi's (Reza Khan) abdication in 1941 British functions were merely consular.

By the 1930s oil developments had made the United States the principal western influence in Saudi Arabia, but later discoveries led to greatly increased British political activity. To prevent the exploitation of the Gulf rulers, Great Britain persuaded them not to grant oil concessions without approval but did not hinder reputable non-British companies from competing for concessions.

The oil industry led to air travel, making the Gulf as important a link between East and West as it had been in the 16th century. An Anglo-Persian agreement in 1928 resulted in Imperial Airways

establishing a service along the Persian coast in 1929 but the route was, in 1932, transferred to the Arabian coast via Basra, Bahrain, Ash Shariqah, and Gwadar to Karachi. By the outbreak of World War II, the British, Dutch, and French were operating regular services to the Far East via these ports.

After World War II.—World War II made little direct impact on the Persian Gulf. The British residency at Bushire was moved to Bahrain in 1946 and in 1947 full control of British interests was transferred to the foreign office.

Militant nationalism ended Britain's close relations with Persia (Iran after 1935). The Soviet-supported Tudeh Party organized a strike at the Abadan oil refinery and in the Khuzistan oil fields in 1946. In 1951, with Muhammad Mossadegh (*q.v.*) as prime minister, the government of Iran nationalized the oil industry. The Abadan refinery was closed and the British staff of the Anglo-Iranian Oil Co. was withdrawn. Diplomatic relations were broken off in 1952 and were not resumed until December 1953. A solution of the oil dispute was not reached until 1954 when a consortium was formed to operate the oil fields (see *Oil* above).

Britain's ties with Bahrain, Qatar, and the seven Trucial sheikhdoms (Abu Dhabi, Dubai, Sharjah, Ajman, Umm al Qaiwain, Ras al Khaimah, and Fujairah) continued on their former footing. A British political resident at Bahrain was in charge of relationships with these states: subordinate to him were British political agents at Bahrain, Qatar, Abu Dhabi, and Dubai. The treaty signed in 1899 with Kuwait was replaced in 1961 by an agreement under which Britain undertook to help the Kuwaiti government if so requested. Kuwait thus became fully independent. The Sultanate of Muscat and Oman remained an independent state, bound to Britain only by treaty relationship. Britain maintained a consul-general and a vice-consul at Muscat who were subordinate to the resident at Bahrain. Consuls at Dhahran (Az Zahran) and Kuwait looked after the important interests the United States had in the Gulf area through its oil companies.

By 1961 there were international airports at Basra, Abadan, Bahrain, Dhahran, and Kuwait. Regional airports included Ad Dawhah (Dohah), Abu Dhabi, and Muscat, and there were many additional landing strips.

Other developments of the postwar period were:

In 1949 Saudi Arabia claimed the Al Buraymi Oasis, an area potentially rich in oil. The claim was disputed by Muscat and Oman and by Abu Dhabi, supported by Great Britain. The course of the dispute is described in SAUDI ARABIA: *History*.

In 1955 the imam of Oman, Sheikh Ghalib bin Ali, attempted to establish Oman as an independent state. This led to a prolonged struggle between the imam and the sultan of Muscat, for an account of which *see* MUSCAT AND OMAN.

In 1961, following the termination of the 1899 agreement with Great Britain, Kuwait was claimed by the Iraqi prime minister, Abdul Karim Kassem, as an integral part of Iraq. Threatened with invasion Sheikh (Sir) Abdullah as-Salim as-Sabah appealed to Great Britain for help. The danger was averted by the dispatch of British troops, which were later replaced by Arab units after Kuwait had joined the Arab League.

Political Trends.—After the seizure of the Abadan refinery in 1951 British influence in Iran declined and when diplomatic relations between the two countries were resumed in 1953 they were on a different footing.

In the political calculations of the Arab states Arab nationalism became a factor of increasing importance. At the same time the influence of the United States in the Middle East generally and in Saudi Arabia in particular made itself felt throughout the area of the Persian Gulf. *See* also IRAQ; IRAN; BAHRAIN; KUWAIT; QATAR; TRUCIAL OMAN.

PERSIAN HISTORY. The name "Persia" in its strict significance denotes the area inhabited by the people known as Persians; *i.e.*, the district known in antiquity as Persis (*q.v.*), the modern Fars. In western countries, following classical usage, custom extended the designation to the whole Iranian plateau and then to the empire and political state occupying most of that region of southwest Asia.

The archaeology of this area is dealt with in the article on the modern country, IRAN. This article discusses the history of Persia from the earliest period to contemporary times and is divided into the following sections:

I. Pre-Achaemenid History
II. Achaemenid Empire
III. Hellenistic Period
IV. Parthian Empire, 2nd Century B.C.—3rd Century A.D.
V. Sasanian Empire, *c.* A.D. 224–651
VI. From the Fall of the Sassanids to the Rise of the Safavids, 651–1501
VII. Safavids, 1501–1736
VIII. Afsharids, 1736–49
IX. Zand Dynasty, 1757–94
X. Qajar Dynasty, 1794–1925
XI. Pahlavi Dynasty

I. PRE-ACHAEMENID HISTORY

Ancient Ethnography.—In the 3rd and 2nd millenniums B.C. the Zagros mountain chain was inhabited by the Guti, whose territory lay north of the Sulaymaniyah; the Lullubi in the Shehrizor district; the Elamites who occupied the plain of Susiana and the surrounding hill country; and the Kassites to the northeast of Elam. Elamite was an agglutinative (noninflective) language, related to no other known tongue. Kassite appears to be connected with a linguistic group found in the Caucasus.

Among the Kassites, however, there was a second linguistic element. The names of Kassite kings of Babylonia are compounded with the names of Indo-European gods, for example, the pest-god Maruttash and the sun-god Shuriash, which may be compared respectively with Sanskrit Marut and Surya. It is, therefore, to be presumed that prior to the Kassite invasion of Babylonia in the late 18th century B.C. an Indo-European people had entered Iran and imposed itself as a ruling aristocracy on the native Kassite tribes. This migration formed part of an extensive movement of Indo-Europeans into Asia. About the beginning of the 2nd millennium the Hittites and related peoples appeared in Asia Minor; by the 16th century B.C. another group, who worshiped the Aryan gods Mithra, Varuna, Indra and the Nasatyas, had seized the leadership of the native Hurrian population of north Mesopotamia; and about the 15th century the Vedic Aryans reached northwest India. Some authorities, for example G. G. Cameron and A. T. Olmstead, maintain that the Indo-Iranian Medes and Persians also occupied the highlands of northern Iran early in the 2nd millennium. These tribes, however, do not appear in the records until the 9th century, and the view of E. E. Herzfeld and R. Ghirshman that they, together with other Indo-Iranian peoples, entered Iran from south Russia at the beginning of the 1st millennium seems more probable.

In the Achaemenid period the principal tribes were the Persians, Medes, Parthians, Arians, Drangians, Arachosians, Bactrians, Sogdians and Chorasmians (for the location of their territories *see* the list of provinces in *Achaemenid Empire: Provincial Administration*, below). They were divided into minor tribes or clans and included both settled and nomadic people. Different dialects of the Old Iranian language were spoken among them. For Old Persian and Avestan, the language of the Avesta or sacred writings of the Zoroastrians which was probably current in northeast Iran, there are contemporary sources. For Median the evidence is indirect. Parthian, Sogdian, Chorasmian (Khwarazmian or Khorezmian) and Bactrian are known from post-Achaemenid sources. The various tribes to the north and northeast of Iran, called Scythians (Saka) by the Persians, also spoke an Old Iranian language or languages. In his inscriptions Darius I of Persia calls himself an Aryan (Ariya) of Aryan lineage. From the term Ariya is derived Middle Persian Eran and modern Iran. (*See* also IRANIAN LANGUAGES.)

Early History to 553 B.C.—Information on the political history of Iran prior to the Achaemenid period is limited to the west-

ern part of the country. Native records are relatively few and intermittent and almost entirely confined to Elam (*q.v.*), where a literate, urban civilization developed early in the 2nd millennium. A native pictographic script, known as proto-Elamite, first appears on clay tablets at Susa and at Sialk, near Kashan, in levels contemporary with the Jamdat Nasr period of Sumer (*c.* 2900 B.C.). The archaeological evidence indicates that Sialk had been forcibly occupied by Elamites, probably as a trading outpost. The proto-Elamite script was derived from that of Sumer, where the first inscribed tablets were earlier in date (*c.* 3100 B.C.). By about 2500 B.C. it had developed into a linear script, which has been deciphered. This died out toward the end of the 23rd century, being replaced by the Akkadian cuneiform script, which, as the result of the political and cultural influence of Sumer, had also been used for writing Elamite since the 25th or 24th century. Very few texts have been found outside Elam and on present evidence it would appear that much of the country remained illiterate until the 1st millennium. The records of Babylonia and Assyria (*q.v.*) are far more informative than the native sources. For political and commercial reasons both countries sought to control western Iran.

The turbulent hill peoples of the Zagros were a perpetual menace to their internal security and to their trade with Iran, which provided essential raw materials in which they were deficient, in particular metal, stone and building timber. Between Babylonia and Elam, which forms part of the south Mesopotamian plain, relations were often intimate but seldom amicable.

In the 3rd millennium the chief districts or cities of Elam were: the commercial centre of Susa; Awan, possibly near Shushtar; Barahshi in the northwest; Anshan in the Bakhtiari mountains of western Persis; and Simash, north of Susiana. Wars between their rulers and the city-states of Early Dynastic Sumer are recorded from about the middle of the millennium, and for a brief period Awan was recognized as suzerain by the whole of Sumer. In the 24th–23rd century Sargon of Agade (*c.* 2370–15, or, according to some authorities, *c.* 2350–2300) and his successors incorporated Elam into their empire and campaigned against the hill tribes of Lullubium and Gutium. Their inscriptions gave the names of Elamite rulers and officials, among them Luhhi-ishan of Awan, the chief opponent of Sargon, who is known from Elamite sources to have been the eighth ruler of his dynasty. At Susa Akkadian influence on the local culture was strong. The Akkadian language largely replaced Elamite and many of the personal names were Semitic. Other parts of Elam may have been less affected since a treaty between Hita, a ruler of Awan, and Naramsin of Agade (*c.* 2290–54, or, according to some authorities, 2267–30) is in Elamite. The rock inscriptions of two kings of Lullubium, near Hulwan, are in Akkadian, however, and the accompanying victory reliefs are modeled on those of Naramsin.

On the breakup of the Akkadian empire about the time of Sharkali-sharri (*c.* 2253–29), western Iran regained its independence. Kutik (Puzur)-Inshushinak of Awan, who as governor of Elam under Naramsin had campaigned as far north as the Kirkuk area, not only rose in revolt but invaded Sumer and Akkad, penetrating to Opis. He expressed the revival of national feeling by reverting to the Elamite script and language and by erecting a temple to Inshushinak, chief deity of Susa. His reign was followed by an obscure period in Elamite history which may be connected with the invasion and domination of Sumer by the Gutians of the northern Zagros, who controlled the country for over a century. After their expulsion the 3rd dynasty of Ur revived the expansionist policy of Sumer. Shulgi (*c.* 2095–48, or, according to some authorities, *c.* 2112–2064) conquered much of Elam and made numerous expeditions into the Zagros. Close commercial relations were developed with Susa, where the Ur kings erected temples and dedicated votive objects to the local gods. During the reign of Ibbi-Sin of Ur (*c.* 2029–06, or *c.* 2046–21) Amorite pressure in the west and internal dissensions so weakened the empire that the Elamites, under the leadership of Simash, were able to regain their independence. About 2006 they sacked Ur, which they held for several years, and carried Ibbi-Sin captive to Anshan, so ending the Ur dynasty. Toward the end of the 20th century Elam for a time fell under the domination of Gungunum of Larsa (1932–06). In 1834 Larsa was itself seized by Kudur-Mabug, probably not, as has been supposed, an Elamite king but an Amorite, whose tribe had settled on the western borders of Elam. In 1764 Elam and Gutium joined with Assyria, Eshnunna and Malgium in an unsuccessful attack on Hammurabi of Babylon.

In 1742 there occurs the first reference to an attack on Babylonia by the Kassites, whose Indo-European leaders must have reached the Zagros prior to that date. In the course of the next 150 years they occupied much of the country and after the Hittite raid of *c.* 1595 entered Babylon. A Kassite dynasty ruled Babylonia until the 12th century. There is no evidence of a Kassite occupation of Elam, but the absence of native records between the 16th and 14th centuries suggests a political collapse which may have been due in part to Kassite pressure on the frontiers.

Elamite recovery began at the end of the 14th century with the establishment of a new dynasty, the members of which bore the title "king of Anzan (Anshan) and Susa." Hubanumena, the third king, inaugurated a policy of foreign conquest, extending his rule as far as the island of Liyan in the Persian gulf. Toward the end of the 13th century Kidin-Hutran twice invaded Babylonia, and 60 years later Shutruk-Nahhunte I attempted to establish permanent control over that country. In 1160 he overthrew Zababa-shum-iddina, appointed a governor and exacted tribute. In 1157 Kutir-Nahhunte removed the last Kassite king, Enlil-nadin-ahhe, who had continued to resist, and carried off the statue of the god Marduk as symbol that Babylonian independence was at an end. Still wider conquests were made by his brother, Shilhak-Inshushinak, the greatest of Elamite rulers. The whole Zagros area as far as the lower Zab river and the borders of Assyria fell into his hands, while in the southeast his rule extended to the Persepolis district. He was, however, unable to hold Babylonia, where power passed to the 2nd dynasty of Isin. Under Nebuchadrezzar I (1124–06) the Babylonians avenged their earlier defeats, invading and plundering Elam and killing Huteludush-Inshushinak, Shilhak-Inshushinak's successor. This victory smashed the power of Elam and for over 300 years its sources are silent.

From the 9th century the political history and geography of the Zagros area are known in some detail from the records of Assyria and Urartu. The principal districts were then Ellipi,

OLIVE KITSON

LOOKING NORTH FROM THE RESIDENTIAL PALACE OF CYRUS THE GREAT TOWARD THE TALL-I-TAKHT OR CITADEL HILL AT PASARGADAE

which extended from the northern border of Elam as far as Kermanshah and Nahavand; Zamua in the Sulaymaniyah district; Manna, south and east of Lake Urmia; and to the southwest of the lake Parsua or Parsuash, probably the first halting place of the Persians in western Iran. Southeast of Manna lay Mada (Media), the territory of the Median tribes, which included Hamadan (ancient Echatana) and extended as far as Mt. Demavend. Parsua and the Medes are first mentioned by Shalmaneser III in 835 and thereafter occur with increasing frequency in the Assyrian records. The settlement pattern in these districts of western Iran was one of scattered villages and occasional fortified citadels, such as those excavated at Hasanlu in Manna and at Sialk. The economy was based on agriculture, but metalworking was highly developed, particularly in Manna, and horse breeding was important, western Iran being the main supplier of horses to the Assyrian army.

During the 9th century the Assyrians won control of all the Zagros from Manna to the borders of Elam. Local rulers and tribal chiefs were laid under tribute and, where possible, Assyrian garrisons were established at strategic points. Nevertheless constant and arduous campaigning was necessary to maintain Assyrian authority. When at the end of the century the power of Assyria declined, Urartu (*q.v.*) under Menuas I and Argistis I expanded south into Manna and Parsua. Tiglath-pileser III (745–727) drove the Urartians back, but in the time of Sargon II (722–705) their anti-Assyrian intrigues led to serious revolts in Manna in which Indo-Iranian chiefs were implicated. Sargon re-established Assyrian authority and also conducted punitive expeditions against Parsua and Mada, in 713 receiving tribute from 45 Median chiefs.

In the south the re-emergence of Elam as a strong military power presented a serious threat to Assyrian interests in the central Zagros and in Babylonia, now an Assyrian vassal state. For over 30 years its kings actively supported anti-Assyrian elements in these territories. Humbanigash of Elam formed an alliance with the Chaldean Merodach-baladan, who in 721 had revolted against Sargon and seized the Babylonian throne, and in a battle fought at Der in 720 compelled the Assyrian to abandon his campaign against the rebel. Although his successor, Shutruk-Nahhunte II, failed to support Merodach-baladan when Sargon renewed his attack in 710, he assisted his revolt against Sennacherib in 703. In 707 he was also involved in an anti-Assyrian intrigue in Ellipi. The failure of both these undertakings was probably the cause of his overthrow by his brother, Hallushu-Inshushinak, in 699. In 694, while Sennacherib was campaigning against Chaldean rebels in the marshlands at the head of the Persian gulf, Hallushu-Inshushinak raided Babylonia, captured its governor, Sennacherib's son, and set Nergal-Ushezib on the Babylonian throne. He was unable to prevent the removal of his nominee by Sennacherib, however, and in 693 was deposed by his disappointed subjects. Within ten months his successor, Kudur-Nahhunte, was assassinated, following an Assyrian attack on Elamite territory, and was succeeded by Huban-immena. In co-operation with the Chaldean Mushezib-Marduk, Aramaeans of the east Tigris districts, Ellipi and other peoples of western Iran, Huban-immena mounted a major offensive against the Assyrian forces in Babylonia (691). In 689, however, he was smitten with a fatal paralysis and the Elamite forces withdrew. Weakened by the long struggle with Assyria and by the pressure of the Persian tribes on its frontier, Elam was torn by rival factions and ceased to be a major force in international politics. Henceforth no single ruler exercised effective authority over the whole country, which was split up among a number of independent princes.

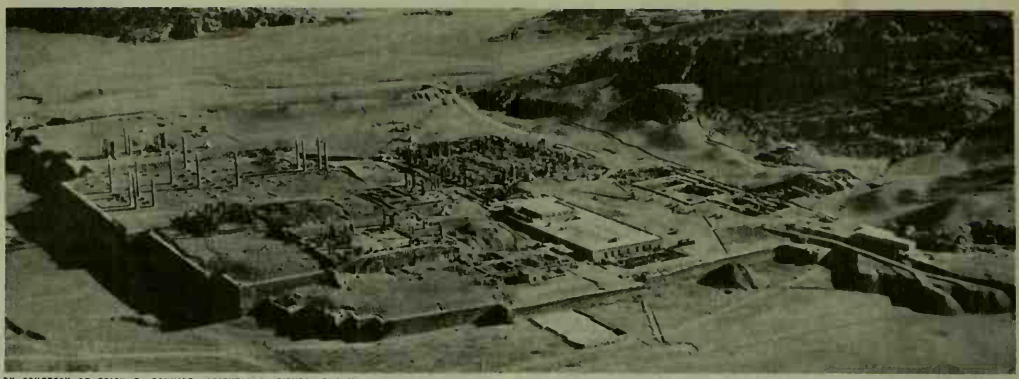
Early in the 7th century Scythian and Cimmerian hordes swept into Iran from the north. In Manna they allied themselves with the local ruler against Assyria and despite the claim of Esarhaddon (681–669) that he suppressed the revolt it is evident that by about 674 his control of the district was seriously weakened. In 676 he made a successful raid through Mada as far as Patusharri, a district on the edge of the Salt desert bordering Mt. Demavend, and the most easterly point in Iran ever reached by an Assyrian army. It may have been in connection with this campaign that he reinstated three Median chieftains who had appealed to him for help against their rebellious subjects. The location of their territories is uncertain. One of them, Ramataia of Urukazabarna, together with seven other rulers of western Iran, in 672 signed treaties with Esarhaddon, the purpose of which was to secure the succession of Ashurbanipal to the Assyrian throne. Relations between Elam and Esarhaddon were cordial, but the intrigues of Tepti-Huban-Inshushinak (*c.* 663–653) provoked an attack by Ashurbanipal in which the Elamite was slain. In an attempt to secure a pro-Assyrian policy in Elam Ashurbanipal placed two Elamite princes, to whom he had given asylum, on the thrones of Hidalu and Madaktu. Enmity toward Assyria, however, was too deep rooted for this maneuver to have any chance of success. When in 652 Shamash-shum-ukin of Babylon revolted from Ashurbanipal, Huban-nugash of Madaktu sent a strong force to his assistance. Although military defeats led to rapid changes of rulers, the Elamites continued to support Shamash-shum-ukin and, following his defeat and death, the rebel Chaldean Nabu-bel-shumati. After a further unsuccessful attempt in 646 to install an Assyrian nominee in Elam, Ashurbanipal invaded the country, sacked Susa with great ferocity and ended Elamite independence (*c.* 639).

Thereafter Assyrian sources fail. In 615, as recorded in the Babylonian chronicle, the Median tribes, united under Cyaxares (*q.v.*; Uvakhshatra), had begun the attack on Assyria which was to lead in 612 to its overthrow. According to Herodotus the Medes were united into a strong, independent confederation by Deioces (*q.v.*) at the beginning of the 7th century. This account cannot be reconciled with the Assyrian evidence. Although some authorities identify Deioces with a certain Daiukku (Dayukku), who in 715 participated in an unsuccessful revolt of Manna against Sargon, it is evident that in the time of Esarhaddon there was no unity among the Medes, many of whose chieftains recognized Assyrian suzerainty. The movement toward unification, the driving force of which was resistance to Assyria, may, however, have started in 674 when Medes, Cimmerians and Mannaeans united against Esarhaddon under the Mede Kashtaritu (Iranian Khshathrita), generally identified with the Phraortes (*q.v.*), son of Deioces, of Herodotus. According to Herodotus, Phraortes was killed in battle against the Assyrians, but before his death he had made the Persians subject to the Medes.

By this date the Persians had migrated to Parsa (Persis; modern Fars), and were led by Teispes (*c.* 675–640), perhaps the son of Achaemenes (*c.* 700–675), the eponymous ancestor of the Achaemenid dynasty. Their territory included the Elamite district of Anshan. The sons of Teispes, Cyrus I and Ariaramnes, were both kings, and each was followed by kings in his own line. In the opinion of some authorities this implies that the kingdom of Teispes was divided between them; an alternative view is that there was alternation in succession between the senior and junior line. Following the final campaign of Ashurbanipal against Elam, Cyrus I acknowledged Assyrian overlordship, sending his eldest son, Arukku, to Nineveh as hostage (*c.* 640). On a gold tablet, Ariaramnes calls himself "great king, king of kings," a title that should imply that he was an independent ruler and leader of a considerable federation. This inscription, however, is considered by some scholars to be a forgery of late Achaemenid date.

Herodotus states that Cyaxares, the son of Phraortes, was for 28 years subject to the Scythians. On regaining his independence, he reorganized the Median army, hitherto a loose mass of tribal contingents, dividing it on the Assyrian model into bodies of spearmen, archers and cavalry. With this united and formidable fighting force the Medes were at last a match for the Assyrians and took the leading part in the destruction of their empire. The Babylonian chronicle records that in 615 Cyaxares invaded the Assyrian province of Arrapkha (Kirkuk). In 614 he took Tarbisu, near Nineveh, and then sacked Ashur. There is archaeological evidence that he also attacked Kalakh (Nimrud). After the sack of Ashur he concluded a treaty with Nabopolassar of Babylon, who since his revolt in 626 had been engaged in attacks on Assyrian territory. In 612 the Medes and Babylonians, probably reinforced by Scythians, sacked Nineveh.

In 610 their capture of Harran ended the last Assyrian resistance in Mesopotamia. While Babylonia won control of the western provinces of the Assyrian empire, Cyaxares extended his power in



BY COURTESY OF ERICH F. SCHMIDT, ORIENTAL INSTITUTE, THE UNIVERSITY OF CHICAGO

AERIAL VIEW OF THE RUINS OF PERSEPOLIS, ONE OF THE CAPITALS OF PERSIA DURING THE ACHAEMENID PERIOD

Iran and Asia Minor. By 590 the conquest of eastern Anatolia had brought him to the borders of Lydia and for five years he was involved in inconclusive fighting with its ruler, Alyattes. The war ended in 585 when a battle was interrupted by a solar eclipse. By a treaty, for which Nebuchadrezzar of Babylon and the ruler of Cilicia acted as mediators, the two powers recognized the river Halys as their common boundary. Cyaxares was succeeded by his son Astyages (Arshtivaiga) *c.* 585.

In Persian territories, once again subject to Media, Ariaramnes was followed by his son Arsames, called "king of Parsa" in an inscription which, like that of his father's, is of uncertain authorship. In the other branch of the family Cyrus I was followed by Cambyses I, called by the Babylonians "king of Anshan," and in 559 by Cyrus II the Great.

II. ACHAEMENID EMPIRE

Political History.—The history of the Achaemenid empire is treated under individual kings (*see* also *History* sections of BABYLONIA AND ASSYRIA; EGYPT; GREECE). This article gives only a brief conspectus of the main events. The order of kings is as follows:

Cyrus II (559–530)
Cambyses II (530–522)
Smerdis (Gaumata) (522)
Darius I (522–486)
Xerxes I (486–465)
Artaxerxes I (465–424)
Xerxes II and Secydianus or Sogdianus (424–423)
Darius II (423–404)
Artaxerxes II (404–359/358)
Artaxerxes III (359/358–338/337)
Arses (338/337–336/335)
Darius III (336/335–330)

The chronology is established by the Ptolemaic canon, by numerous Babylonian and a few Egyptian documents and by the evidence of the Greeks.

In 553 Cyrus II rebelled against Astyages, having previously formed an alliance with Nabonidus of Babylonia, who wished to evict the Medes from Harran. In 550 Cyrus captured Astyages and made himself master of the Median confederation. Nabonidus took Harran but soon realized that Cyrus constituted a greater danger to his empire than Astyages, in whose overthrow he had assisted. When war broke out between Cyrus and Croesus of Lydia, possibly in 547, Nabonidus entered into an alliance with Croesus, as did Egypt and Sparta. Before help could be sent, however, Cyrus defeated Croesus and seized Sardis. During the next few years he and his generals secured the submission of the rest of Asia Minor and probably detached part of Syria and Palestine from the Babylonian empire. The attack on Babylonia itself opened in 540 and Babylon fell the following year. Cyrus also subdued northern and eastern Iran, but details of these campaigns are unknown. He died in 530 in battle against the nomads of eastern Iran. In the brief span of 20 years he had raised an obscure and secluded tribe to the mastery of an empire that stretched from the Mediterranean to the Indus. Able generalship and the fighting qualities of the Persian army contributed to this remarkable achievement, but a major factor was the liberal and lenient treatment accorded by Cyrus to conquered states, a policy without parallel in the previous history of the near east. In consequence many peoples welcomed him as a liberator from existing tyranny, whether foreign or native. Thus it is probable that the provinces of the Babylonian empire offered him little, if any, resistance, while in Babylonia he had the support of a large part of the population and, in particular, of the priesthood, which had been antagonized by the religious policy of Nabonidus.

The conquest of Egypt, which had shown its hostility to Persian expansion by allying itself with Croesus, was carried out by Cambyses II in 525. The usurpation of the Persian throne by Smerdis (Gaumata) in 522 and his assassination by Darius I led to serious revolts in Iran and Babylonia and the defection of the Persian governors of Egypt and Sardis. Lack of co-ordination among the rebels, however, enabled Darius to deal with them individually, and by 518, when he visited Egypt, he had established his authority and restored order throughout the empire. The revolts had nevertheless demonstrated the strength of separatist tendencies and, while not departing from the system devised by Cyrus, Darius took steps to strengthen the imperial administration. He completed the division of the empire into provinces, introduced checks on the power of their governors and fixed the annual taxation of each province. In foreign policy his main concern was to counter external threats to the security of the empire. To protect his northern borders from incursions by the Scythian nomads he attacked the tribes east of the Caspian in 519 and those of European Scythia in 513. Although the latter expedition had to be abandoned because of failure of supplies, it resulted in the submission of Macedonia, Thrace and the islands of Lemnos and Imbros. He thus held the approaches to Greece, conflict with which was inevitable, for Persian control in western Asia Minor was threatened by the support given by the Greeks to their Asian kinsmen. Nevertheless it was not until Athens and Eretria assisted the Ionian revolt of 499 that Darius attacked European Greece. The expeditions led by Mardonius (492) and Datis (490) were unsuccessful, and the carefully prepared campaigns of Xerxes ended in the defeats of Salamis (480), Plataea and Mycale (479). The victory of Cimon on the Eurymedon followed *c.* 466. The invasion of Greece had failed completely, largely through the military and diplomatic blunders of the Persian king and his commanders. The European territories were lost and large numbers of Asian Greeks, Carians and Lycians joined the Delian league.

The failure of Xerxes' expeditions proved a turning point in the history of the empire. Although the territorial losses were of no great significance, its prestige and military strength had suffered a severe blow and thereafter it declined into a condition of immobility and stagnation, a process which was assisted by the deteriorating influences of civilization and imperial power

on the character of the ruling race. The royal line degenerated and the successors of Darius were weak, capricious, pleasure-loving potentates, easily accessible to personal influence. Only the brutal Artaxerxes III possessed the will and energy to prosecute a vigorous and positive policy. At court the influence of the royal harem and the eunuchs made disastrous progress, dynastic disputes became frequent and intrigue and corruption were rife. Men of energy and ambition began to find the temptations of power stronger than their patriotism and loyalty to the crown. High court officials such as Artabanus, who murdered Xerxes, and Bagoas, the assassin of Artaxerxes III and Arses, attempted to seize the reins of power in fact if not in name. In the provinces, satraps aspired to independence and as the central authority weakened and the checks on their power diminished their revolts became more frequent and dangerous. In considering the subsequent wars and disorders, however, it must be borne in mind that they usually affected restricted parts of the empire; only on isolated occasions were extensive areas involved in prolonged strife. For most of the provinces the Achaemenid domination was synonymous with two centuries of peace, order and improved economic conditions.

Under Artaxerxes I and Darius II the situation in the empire remained stable. Isolated satrapal revolts and a rising in Egypt were suppressed and Persian diplomacy, backed by gold, was able to exploit the dissensions of the Greeks to Persian advantage. Athens had not the strength to undertake a serious offensive against the empire. It failed in its attempts to detach Egypt and Cyprus from Persia, and *c.* 448 its difficulties with the other Hellenic states constrained it to conclude the peace of Callias whereby it renounced the Persian war while Artaxerxes acknowledged the loss of the cities in Asia Minor under Athenian rule. The collapse of Athenian power before Syracuse (413), however, gave Darius the opportunity to regain the lost territories. An alliance was formed with Sparta, part of Ionia was recovered and Persian subsidies enabled Lysander to complete the overthrow of Athens in 405. When war subsequently broke out with Sparta, Artaxerxes II supported its Greek adversaries. The annihilation of the Lacedaemonian fleet at Cnidus in 394 crippled Spartan power and gave Persia the mastery of the Aegean. Exhausted by their struggles, the Greeks in 386 accepted the peace of Antalcidas and recognized Persian rule over the Greek cities of Asia Minor and Cyprus. Persia became the arbiter of Greece, and the feuds that followed centred on the efforts of the combatants—Sparta, Thebes, Athens and Argos—to secure Persian support. The goal for which Darius and Xerxes had striven had at last been achieved, but the Persian success was due to the internecine strife of the Greeks rather than to Persian military efforts. The weakness of the empire was revealed by the revolt of Cyrus the Younger, the failure of the two expeditions sent against Egypt, which had rebelled in 404, the loss of Paphlagonia, Bithynia and other districts in Asia Minor and the widespread satrapal revolts in Asia Minor and Syria. That the weakness of Artaxerxes II was in large measure responsible for these calamities, which threatened to disrupt the empire, is shown by the swift recovery of Persia under his able and energetic successor, Artaxerxes III. He curbed the power of the satraps, compelling them to dismiss their Greek mercenaries, forced Athens, which had supported some of them, to conclude peace (355) and, after an initial reverse, reconquered Egypt (343). As a result of these measures the empire appeared to be more powerful and more firmly established than at any time since Darius.

In the Greek world, however, the rise of Philip II of Macedonia had fundamentally changed the situation. Philip's immediate purpose was Macedonian expansion at the expense of Thrace and Thessaly and the subjugation of the Balkan peninsula, but in his efforts to extend his power over the Greek states he was bound to assume the leadership of the movement which, inspired by writers such as Isocrates, aimed at the unification of Greece for the struggle against Persia. Artaxerxes, pursuing the traditional Persian policy, supported Perinthus, Byzantium and Athens against Macedonia, but in 338 Philip defeated Athens and in 337 formed the League of Corinth, embracing the whole of Greece except Sparta, for the purpose of liberating the Greeks of Asia Minor from Persian rule. The invasion of Asia Minor, begun by Philip in 336, was resumed by Alexander (334; *see* ALEXANDER III the Great) after Philip's assassination. By the autumn of 333 Alexander had won most of Asia Minor and defeated Darius III at Issus. It was probably after Issus that he first thought of conquering the whole Persian empire. To hold Asia Minor meant a defensive war, since Persia would certainly seek to regain it; Phoenicia and Egypt were known to be disaffected; and the superiority of the Greek army over that of Persia had been decisively demonstrated. The overtures of Darius were therefore rejected. Except at Tyre and Gaza Alexander met no serious resistance and the occupation of the western provinces, including Egypt, was completed by 332. In 331 Darius was defeated at Gaugamela (*see* GAUGAMELA, BATTLE OF) and fled to Bactria, where in 330 he was murdered by Bessus. Although it took Alexander several years to complete his conquest of Iran, the victory at Gaugamela gave him the mastery of Asia and brought the Achaemenid empire to an end.

The Monarchy.—The Achaemenid king ruled by divine right. "By the grace of Ahura Mazda I am king; Ahura Mazda gave me the kingdom," says Darius I, and on the monuments Ahura Mazda, in the winged disk, regularly hovers over the king, symbolizing the divine favour and protection so much insisted on in the royal inscriptions. The succession was hereditary, but the rule of primogeniture does not appear to have been strictly observed. The king

apparently had the right to choose his successor from among his sons and was expected to do so before risking his life in foreign war. Thus 12 years before his death Darius named as heir apparent not his eldest son but Xerxes, the first son born to him after his accession. Notwithstanding the nomination of a crown prince the succession, after the time of Xerxes, was frequently disputed, harem intrigues being a main cause. The succession of a new king was generally followed by the assassination of close relatives; in consequence the royal house was so decimated that on the death of Arses the throne passed to a collateral branch.

While the power of the king was, at least in theory, absolute, he acted in consultation with his high officers of state. There are references in Ezra to seven counselors, but there is no exact information on their titles and functions. It is probable that the *hazarapat* (Greek *chiliarchos*), the commander of the royal bodyguard, was the foremost among them; his office corresponded to that of vizier. The head of the chancellery must also have occupied a leading position in the government. The chief Persian and Median nobles were closely connected with the court. Among them the descendants of the six men associated with Darius in the murder of Gaumata held the highest rank and were influential in the king's counsels. They alone had the right to enter the royal presence unannounced and possessed princely estates.

Provincial Administration.—The Persian empire was far more extensive and comprised a greater variety of peoples than any that preceded it. In relation to the subject population the Persians were in a small minority. They were, moreover, inferior in civilization to the ancient nations that lay to the west of Iran. To hold the empire by force alone was therefore an impossibility. Recognizing this, Cyrus and Darius sought to govern by persuasion and consent. Propaganda was effectively used as an instrument of policy, especially by Cyrus. Vanquished peoples were treated with clemency and permitted as much freedom in the conduct of their affairs as was consonant with the efficiency of the imperial administration. This policy, however, was only partially successful in reconciling the subject populations to foreign domination, and national revolts led to departures from the liberal principles laid down by Cyrus.

Among the peoples of the empire the Persians occupied a leading and privileged position, for it was on their loyalty that the Achaemenid dynasty ultimately depended. They alone were exempt from taxation. They were liable for military service, however, and, together with the Medes, provided the standing army. Persian military colonists were settled in the provinces and endowed with lands; they formed the nucleus of the provincial levies and were the mainstay of the satrapal governments. The leading Persian families supplied the majority of the army commanders and the chief officers of the central and provincial administration. To train them in their duties, sons of the nobility were brought up at the royal and satrapal courts, where they were instructed in the handling of arms, riding and hunting, and in history, religion, law and judicial procedure.

Although for geographical reasons the administrative capital of the empire was Susa, the associations of the monarchy were with the ancestral homeland of the dynasty. The kings were buried in Persis and were consecrated at Pasargadae, the city of Cyrus II. In the interior of the country Darius founded the city of Parsa, the Persepolis of the Greeks, the most magnificent of the royal capitals. Pride of race and country was strong in king and people. Darius calls himself "a Persian, the son of a Persian, an Aryan of Aryan stock."

The Achaemenid monarch was no less conscious of his unique position as supreme ruler of a great diversity of nations. Darius was "one king of many, one lord of many, . . . the great king, king of kings, king of the countries possessing all kinds of peoples, king of the great earth, far and wide." In the subject territories Persian rule was direct, native dynasties being suppressed and replaced by Persian governors. Only in a few states which had submitted voluntarily were native kings permitted to remain in vassalage to Persia.

This was the case in Cilicia, where the governor belonged to the native royal house, and in Byblos, Sidon and Citium (in Cyprus), the rulers of which, although subordinate to a Persian governor, called themselves kings. In Babylonia Cyrus retained the monarchy but assumed the kingship himself, adopting the title "king of Babylon," a measure designed to flatter national pride and reconcile the Babylonians to foreign rule. In his official pronouncements he represents himself as the king chosen by Marduk, the national god, and therefore the legitimate successor to the Babylonian throne.

A similar policy was followed by Cambyses and Darius in Egypt. The revolts of Babylonia and Egypt against Xerxes led, however, to a change of policy. The Babylonian monarchy was abolished, the statue of Marduk, without which no king could legitimize his rule, being destroyed. In Egypt Xerxes refused to adopt the native royal titulary, thus abandoning the fiction that he was the legitimate successor to the Pharaohs.

The empire was divided into provinces, the number and limits of which varied with changes in the imperial frontiers or in the administration. Different lists are incorporated in the inscriptions of Darius I. The earliest, in the Bisitun text (completed by 518 B.C.), gives 23 lands, and the latest, in the tomb inscription, 30, as follows:

The Iranian provinces of:

1. Persis (*q.v.*; Parsa) in modern Fars, which probably included Carmania (Karmana) to the east;
2. Media (*q.v.*; Mada) in the northwest;
3. Elam (*q.v.*; Huvja) in Khuzistan;
4. Parthia (*q.v.*; Parthava) in Khurasan, which at this date included Hyrcania (Varkana) southeast of the Caspian sea in the Asterabad (Gorgan) district;
5. Aria (Haraiva) along the Arius (Harirud) river;
6. Bactria (*q.v.*; Bakhtrish) on the northern slopes of the Hindu Kush as far as the Oxus (Amu-Darya) river, to which was joined Margiana (Margu), centred on the oasis of Merv, which preserves the ancient name;
7. Sogdiana (Suguda), the mountainous region between the Oxus and Jaxartes (Syr-Darya) rivers;
8. Chorasmia (Uvarazmish), the Khiva oasis along the lower Oxus which still bears the name Khwarizm;
9. Drangiana (Zranka; Sarangia in Herodotus) along the Helmand river in Seistan;
10. Arachosia (Harahuvatish), the district of the Helmand river and its tributaries round Kandahar;
11. Maka, probably Makran.

The three provinces lying east of Iran:

12. Sattagydia (Thatagush), of uncertain location;
13. Gandhara (Gandara), also called Paruparaesanna (Paropamisidae, "the land beyond the mountains"; *i.e.*, the Hindu Kush) in the Kabul valley;
14. India or Sind (Hindush) in the Indus valley.
15. The *hauma*-preparing (?) Scythians (Saka haumavarga; the Amyrgian Scythians of Herodotus) in the Pamirs.
16. The pointed-cap Scythians (Saka tigrakhauda) east of the Caspian sea.
17. Babylonia (Bahairush).
18. Assyria (Athura; Aramaic Ebir-nari, "across the river" [Euphrates]), which included Syria, Phoenicia and Palestine and prior to Xerxes was administered jointly with Babylonia; the later list of Herodotus includes Cyprus in the province.
19. Arabia (Arabaya).
20. Egypt (Mudraya).
21. The Libyans (Putaya).
22. The Ethiopians (Kushaya).
23. Armenia (Armina), which according to Herodotus stretched to the Black sea.
24. Cappadocia (Katpatuka).
25. Lydia (called Sparda after Sardis the capital).
26. Ionia (Yauna).
27. Scythians across the sea (Saka paradraya) on the steppe north of the Black sea.
28. Thrace and Macedonia (Skudra).
29. Ionians wearing the petasos cap (Yauna takabara), elsewhere called (Ionians) "by the sea" (Tyaiy drayahya), possibly to be identified with Hellespontine Phrygia.
30. Carians (Karka).

To these provinces a list of Xerxes adds Dahae (Daha), east of the Caspian, and "men of the mountain land" (Akaufaciya), of uncertain location.

The list of tributary provinces given by Herodotus, which must have been derived ultimately from an official Persian source, perhaps of Artaxerxes I, differs considerably from those of Darius and Xerxes. The reduction in the number to 20 reflects the loss of territory in Europe and administrative changes. A number of lands previously listed separately are combined, notably Parthia, Chorasmia, Sogdiana and Aria (province xvi), Drangiana and the

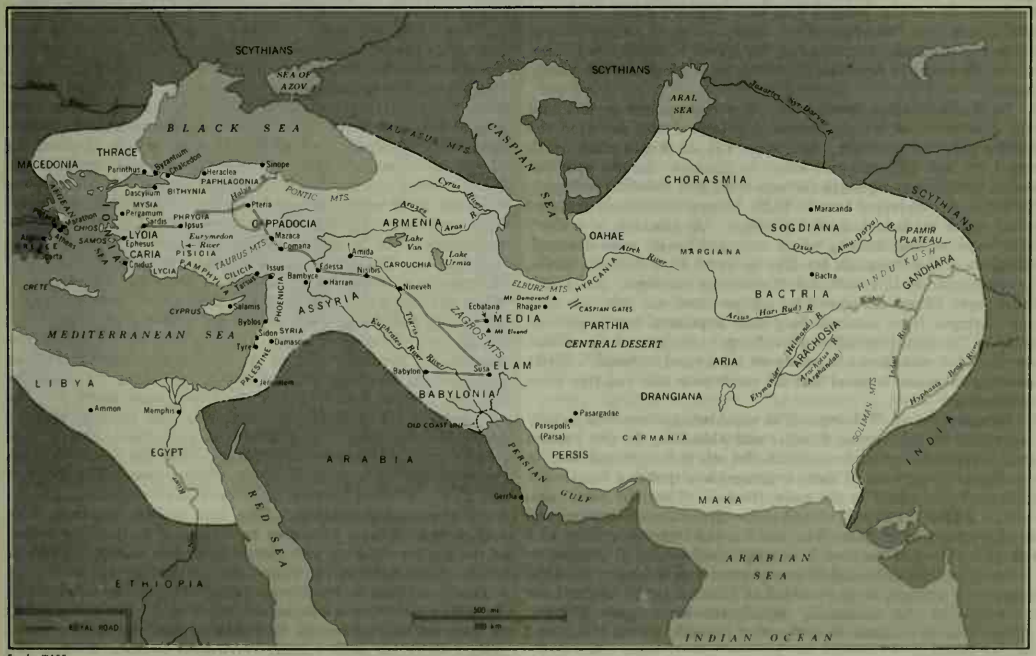
AERIAL VIEW OF THE RUINS OF SUSA, CAPITAL CITY OF THE PERSIAN EMPIRE AT THE TIME OF DARIUS I

Mycians (Maka) with other tribal districts and islands in the Persian gulf (xiv), Sattagydia and Gandhara (vii) and Egypt and Libya with Cyrene and Barca (vi). Caria is joined to Ionia, which also includes Magnesia on the Maeander (Menderes) river, the Aeolians, Lycians, Milyans and Pamphylians (i). Cappadocia includes the Hellespontines or Greeks of northwest Asia Minor, Phrygia, Asiatic Thrace or Bithynia, Paphlagonia and the Mariandynians (iii). This province was sometimes called Dascylitis by the Greeks after the capital Dascylium. Herodotus gives a number of provinces which do not appear in the Achaemenid lists, for example Cilicia (iv), and omits Persis because it was exempt from taxation and Arabia and Ethiopia because they did not pay a fixed annual tribute.

The central government retained rights over foreign policy and the assessment of tribute, but the provinces were as far as possible



E. J. WASS

THE PERSIAN EMPIRE IN THE TIME OF DARIUS I AND XERXES I (ACHAEMENID PERIOD)

left to govern themselves. Each was under a governor or satrap (*q.v.*), normally a Persian of high rank, who was head of the civil administration, supreme judicial authority and commander of the provincial troops. Assisting him was a council of Persians and native representatives. It became evident in the time of Darius that such wide powers could encourage the satraps to aim at independence and a system of controls was therefore devised. Garrison commanders in the province were made independent of the satrap; a royal secretary was attached to him to deal with his correspondence with the king; and inspections of the provinces by royal officials were instituted. By the time of Artaxerxes III, however, these controls had weakened and the satraps had greatly increased their military strength by recruiting large numbers of Greek mercenaries.

The subject peoples occupied a tolerably independent position. Their forms of local government were generally retained, their laws and customs were respected and they provided subordinate officers of the provincial administration and army. National revolts led in certain instances, however, to a curtailment of these privileges. Thus in Babylonia Darius replaced many of the native officials by Persians, a process which was accelerated under his successors. The system of local government within the provinces varied according to local conditions. In large cities, such as Babylon, Jerusalem and the Egyptian towns, internal affairs were controlled by the elders or the officials of the community. The great temple dominions, such as Bambyce in Syria and the two Comanas in Asia Minor, were administered by the priests. City-states might have a monarchy, as at Byblos, Sidon and Citium; an aristocracy, as in Bithynia, Caria and Lycia; or tyrants, as in the Greek towns. In tribal districts authority was in the hands of the chieftains. Complete subjection of many of the wild and warlike tribes in inaccessible mountain and desert areas was impossible or not worth the effort. When in 401/400 Xenophon marched from the Tigris to the Black sea, the tribes of the Pontic mountains were completely independent. Outside the authority of the satraps were the royal domains, with great parks and hunting grounds (the paradises), and the estates bestowed by the king on Persians or members of subject peoples who had rendered signal service to the crown (the "benefactors"). Many of these estates formed large principalities; *e.g.*, those of the house of Otanes in Cappadocia, Hydarnes in Armenia, Themistocles in Magnesia and Lampsacus.

To maintain close liaison with the provinces and to facilitate the movement of troops, Darius I improved and extended the earlier network of routes. Best known is the Royal road, which ran from Susa to Sardis and thence to Ephesus. Linked with this was a branch running south through Syria and Palestine to Egypt. Other routes traversed Iran to India. Royal messengers traveled along these roads in a system of relays. At intervals of a day's ride were posting stations where men and horses were changed. Whereas it took caravans 90 days to travel from Susa to Sardis, couriers could by this method do the journey in a week. As Herodotus says: "They are stayed by neither snow nor rain, nor heat nor darkness from accomplishing their appointed course with all speed. The first rider delivers his charge to the second, the second to the third, and thence it passes on from hand to hand." Strict security measures ensured that the roads were safe and free from brigandage.

Language and Writing.—The royal inscriptions were usually trilingual, in Old Persian, Elamite and Akkadian, the Old Persian text being the original from which the others were translated; in provinces where none of these languages was spoken a fourth legend might be added in the native tongue. Thus the Suez canal stelae of Darius I were inscribed in the three official languages and in Egyptian hieroglyphs. The Old Persian text was written in a simplified form of the cuneiform script consisting of 41 characters. In the time of Darius and Xerxes payments to workmen from the Persepolis treasury were recorded in Elamite cuneiform and the personnel of the accounting department was largely Elamite. There is some evidence, however, that the orders were first issued in Old Persian.

Aramaic, with its alphabetic script which could be written in ink on papyrus, parchment or clay, was employed throughout the empire for imperial administration and also for diplomatic correspondence. Royal pronouncements and decrees and enactments of the imperial chancellery were provided with an Aramaic translation, as is shown by an Aramaic copy of the Bisitun inscription preserved among the papyri of the Jewish garrison at Elephantine. In Egypt correspondence between Persian and Egyptian officials and even between Persians was conducted in Aramaic, and in Asia Minor coins minted by Persian satraps and generals usually bore an Aramaic legend. Aramaic characters were adapted for the writing of Iranian languages, the earliest-known example being an inscription in Persian on the tomb of Darius at Naksh-e Rostam dateable to the first half of the 3rd century B.C.

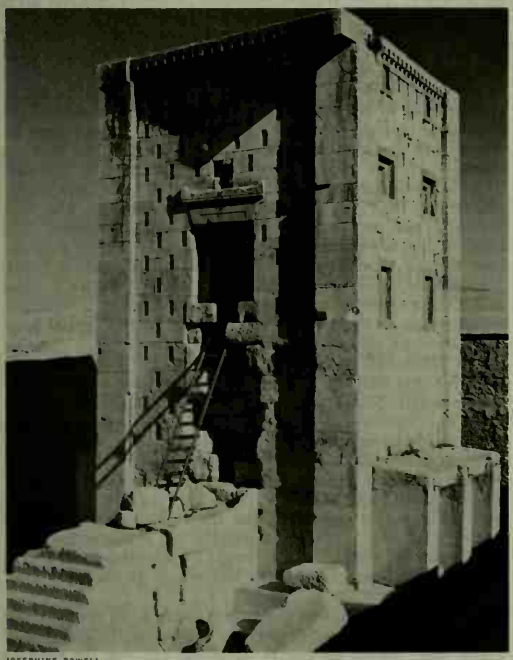
Law.—No collections of Persian laws have survived and information on the legal system is scant. The traditional, tribal law was unalterable, but the king could issue decrees. In matters of law and custom he was advised by the royal judges. They held their office, which was usually hereditary, for life and could be removed only for professional misconduct. Herodotus mentions the case of a judge who was executed by Cambyses II for accepting bribes and giving an unjust judgment. The punishment for treason was death, usually by beheading or crucifixion, but for other crimes the death penalty was not imposed for a first offense. It was customary to weigh the good deeds of an offender against his crime, as for example in the case of another corrupt judge who was reprieved by Darius because of his previous services to the crown. In the provinces the satrap was the chief judicial authority and there were Persian judges. Civil matters in the lower courts were usually decided by native officials in accordance with the native law. In Egypt Darius I caused the native law to be written down by the wise men, priests and scribes. There is evidence, however, that the administration of justice was often corrupt.

Armed Forces.—All the peoples of the empire were liable for military service. The standing army was composed mainly of Persians and Medes. The core troops were the Immortals, so called because their number was never allowed to fall below 10,000, a replacement being always available if a man fell sick or died. The first 1,000 formed the royal bodyguard, which was under the command of the chiliarch. In time of war contingents were drawn from the provinces, each being under the command of the satrap. There were permanent garrisons in the chief cities and border forts, many of the troops being mercenaries, as for example the Jews at Elephantine. In the higher ranks the command was predominantly Iranian. The army was organized in divisions of 10,000, battalions of 1,000, companies of 100 and squads of 10. It was divided into cavalry, infantry and archers. In all branches the usual arms were the bow, spear and dagger, but the equipment could vary according to nationality. Although the spear and dagger might be used in a charge, the bow was the chief Persian weapon. The aim was to overwhelm the enemy with a hail of arrows and never to allow him to come to close quarters. While the infantry knelt to shoot, the cavalry swarmed round the hostile squadrons, threw their lines into confusion and completed their discomfiture by a vigorous pursuit. Since it was essential for the archers to be mobile and their use of the bow to be unhampered, armour and shields were light. The empire was won by such tactics, but in the Greek wars, when once the generalship of a Miltiades or Pausanias had brought about a hand-to-hand conflict, the Persians, despite their bravery, succumbed to the heavily armed hoplites. After the time of Xerxes, therefore, the bow became a subordinate arm. The Persians had plenty of good cavalry, since each landowner maintained a troop of mounted retainers. The foot soldiers, however, were mainly undisciplined tribesmen or serfs, and in the later period of the empire the king and satraps came increasingly to depend on Greek mercenaries for their trained infantry.

The naval forces were supplied by Phoenicians, Egyptians, Cypriots and seafaring peoples of Asia Minor. The commanders of the fleet were, however, high-ranking Persians, and to guard against defection each trireme carried 30 Persian, Median and Scythian marines.

Economic Policy.—The financial basis of the empire was the payment of tax, in cash or kind, by all the subject peoples. Under the fiscal system introduced by Darius I, each province was liable for a fixed annual amount, which was assessed according to its productivity. The largest contributor was Babylonia, which, according to Herodotus, provided 1,000 silver talents, 500 eunuchs and four months' supply of food for the army. Egypt, the granary of the empire, supplied 700 talents, 120,000 measures of grain and profits from the fisheries. From India was exacted gold dust to the value of 4,680 talents. Herodotus assessed the annual cash payments, including the Indian gold dust, at 14,560 Euboic talents. Tax collection was the responsibility of the satrap, who, after deducting the cost of his administration, forwarded the balance to the king. Surplus revenues accumulated as a reserve fund which was stored in the royal treasuries, mostly as bullion, the gold and silver being melted down and poured into clay jars. Estimates of the amount of treasure seized by Alexander the Great vary, but according to Quintus Curtius he found 50,000 talents of uncoined silver at Susa, 120,000 talents at Persepolis and 6,000 talents at Pasargadae. Taxes in kind, which included horses and cattle, foodstuffs, clothing materials and all kinds of manufactured goods, provided for the support of the army and the households of the king and the satraps.

It is difficult to assess the burden of this taxation. It was probably not as onerous as is sometimes suggested, but corruption in the fiscal administration was undoubtedly a major cause of discontent. Against the taxation must be set the economic and social advantages conferred by peace, security and the development of trade among all parts of the empire.



JOSEPHINE POWELL

ZOROASTRIAN FIRE TEMPLE AT NAKSH-E ROSTAM

To facilitate the exact calculation of tax, Darius standardized coinage and weights and measures. The gold coin of 129 gr. was known in Greek as *dareikos*, a word derived by some authorities from the king's name, by others from Old Persian *daraniya*, "gold." It contained about as much gold as an English guinea and was the equivalent of 20 silver shekels. The coinage of gold was the exclusive prerogative of the king, but silver and copper could be coined by the satraps, generals, dynasts and autonomous cities. In the commercial centres of the west, where various forms of metal currency, including coinage, had previously been in existence, this monetary reform was of great advantage to trade and banking, but it can have had little effect in the more backward parts of the empire where the method of exchange was still by barter. The introduction of a money economy to a community which had hitherto known only payments in kind is strikingly illustrated by the wage lists from Persepolis. Payment based on coined money was introduced there by Darius about 493. In the first part of Xerxes' reign two-thirds of the wages were paid in kind and the balance in cash. Later in the reign the payment in kind was reduced to a half and in one instance to a third of the total amount due.

Imperial trade was further assisted by the improvement of land and sea communications. The great road system, while primarily developed for political and military reasons, also served the interests of commerce, as did the completion by Darius of the canal between the Nile and the Red sea and the exploration by Scylax of the sea route between India, Persia and Egypt.

Persian Religion.—During the Achaemenid period the polytheistic nature worship of the Aryan tribes was reformed by Zoroaster (*q.v.*) into an ethical dualism centred on Ahura Mazda (*q.v.*) as the only true god. The prophet preached the new faith in eastern Iran, probably in Chorasmia, in the 7th–6th century. How widely it was spread in its pure form is difficult to determine, but by the 5th century a religion had developed combining certain of Zoroaster's tenets with the cult of the old Aryan gods. (*See* also ZOROASTRIANISM.)

The extent to which the Achaemenid kings were influenced by Zoroaster's teaching is the subject of keen controversy. Inscriptions of the early rulers throw no light on the exact nature of their religious beliefs. Those of Darius I and Xerxes give pre-eminence to Ahura Mazda; no other gods are named, though their existence is recognized. Darius constantly insists on the aid and protection accorded him by Ahura Mazda and also stresses the nefarious role of the lie, which, he says, caused the provinces to rebel against him. Since exclusive devotion to Ahura Mazda and the concept of the dualism of truth and falsehood are basic to Zoroaster's religion, it is considered by many authorities that the beliefs of Darius were ultimately derived from those of Zoroaster, who, however, is never mentioned by the king. It has further been argued that Zoroastrian ideas were introduced into western Iran by Darius and that at first they were adopted only by the royal family and court circle. That the old nature worship continued among the common people is evident from the statement of Herodotus in the 5th century that the Persians sacrificed to the sky, sun, moon, earth, water and winds. Under pressure from the old religion, Zoroastrianism eventually became fully polytheistic. Artaxerxes II and Artaxerxes III invoke not only Ahura Mazda but also Mithra, the ancient Aryan god of the contract, and Anahita, who appears in the Avesta as a goddess of water and later as a fertility deity.

The gods might be represented by their particular symbols. So on Achaemenid reliefs Ahura Mazda is depicted rising from the winged disk, a symbol derived from Assyria though ultimately Egyptian in origin. The worship of divine images, however, was first introduced by Artaxerxes II, who was presumably influenced by cult practices in the western part of the empire. Herodotus says that the Persians had neither temples nor altars, that they offered blood sacrifices but lit no fire and made no libations. Although there is no evidence for temples housing a divine statue, at any rate prior to Artaxerxes II, places of worship certainly existed, for Darius states that he restored those destroyed by Gaumata. The towers at Pasargadae and Naksh-e Rostam are identified by some authorities as fire temples, while a terraced structure at Pasargadae and a building of unusual plan at Susa may also be shrines. Libations by a Magian priest appear to be mentioned in an Elamite tablet from Persepolis. This may refer to the offering of *hauma* (*homa*), an intoxicating drink, well attested for eastern Iran in the Avesta. A

fire altar is depicted on the royal tomb reliefs and also on a tomb at Qez Qapan in the district of the Shehrizor, for which a date of 600–550 is suggested. Actual examples of fire altars standing in the open occur at Pasargadae. The blood sacrifices to the gods are described in detail by Herodotus and Achaemenid kings are frequently mentioned by the Greeks as sacrificing horses and cattle and even on occasion human beings.

Sacrifices could take place only in the presence of a Magus, a member of a separate clan or caste of the Medes. The Magi (*q.v.*) were distinguished by certain peculiar customs, notably exposure of the dead. During the sacrifices they chanted a hymn and held a bundle of reeds (the barsom). They wore felt caps and covered their mouths with a band (*paitidana*) so that their saliva might not defile the sacred fire which it was their duty to tend. In addition to officiating at sacrifices, they participated in the coronation ceremony, guarded the royal tombs, accompanied the army with the sacred fire, interpreted dreams and assisted in the education of the royal princes. They constituted the professional priesthood of western Iran, serving all cults, and it is to their influence that the fusion of Zoroastrian and pre-Zoroastrian doctrines must be attributed.

The Achaemenids adopted a tolerant attitude toward the diversity of religions within the empire. In part this was a matter of policy, for by conciliating the native priesthoods they hoped to win influential support for their rule. This is well illustrated in Babylonia, where Cyrus II presented himself as the defender of the faith against the heretic Nabonidus and as the king chosen by the national god, Marduk. He not only permitted the priests to maintain existing rituals but himself participated in them and also restored the temples. A similar policy was followed by Cambyses and Darius in Egypt, although the former suppressed certain abuses in the temples and thereby earned the enmity of the priests. Cyrus permitted the exiled Jews to return to Jerusalem and rebuild the Temple, a decision which was confirmed by Darius, and Artaxerxes I afforded protection to Ezra and Nehemiah. With all the Greek oracles, even those in Greece, the Persians maintained excellent relations. In Babylonia, however, national revolts caused Xerxes to abandon a conciliatory policy. To prevent any future pretender from legitimizing his rule he destroyed the statue and temple of Marduk.

Sources for the Period.—For the inscriptions of the Achaemenid kings *see* R. G. Kent, *Old Persian: Grammar, Texts, Lexicon* (1950). Important details on the rise of Cyrus to power and his capture of Babylon are contained in the Persian verse account of Nabonidus and the Nabonidus chronicle (*see* S. Smith, *Historical Texts Relating to the Capture and Downfall of Babylon*, pp. 27 ff.; 1924). In the Old Testament, only the contemporary books of Ezra and Nehemiah are of importance, but there are a few statements in the later Esther romance. Information on the struggle of Egypt for independence in the 4th century is given in the *Demotic Chronicle* (*see* W. Spiegelberg, *Die Sogenannte Demotische Chronik*, 1914). The tablets from the Persepolis treasury and fortifications provide important information on religion and economic affairs in the time of Darius and Xerxes (*see* G. G. Cameron, *Persepolis Treasury Tablets*, 1948). Large numbers of business contracts from Babylonia throw light on economic and social conditions in that country. In Egypt Aramaic documents of the 5th century give information on administration and judicial procedure (see *Aramaic Papyri of the Fifth Century B.C.*, edited by A. Cowley, 1923; and *Aramaic Documents of the Fifth Century B.C.*, edited by G. R. Driver, 1957).

Among Greek sources, the most ancient work preserved is that of Herodotus, which is very valuable for the period up to 479. His material was drawn partly from sound tradition, partly original knowledge, as in the account of the satrapies, the Royal road and the army of Xerxes, but there is also much that is fabulous. The physician Ctesias of Cnidus, who for 17 years (414–398) was in the service of Artaxerxes II, composed a great work on Persian history, known from an extract in Photius and numerous fragments. Ctesias possessed a more precise acquaintance with Persian views and institutions than Herodotus did, and where he deals with matters that come under his own cognizance he gives much useful information. For the early period, however, he proves how rapidly the tradition had degenerated since Herodotus, and his narrative must be used with caution. Also of value is the work of Dinon of Colophon (*c.* 340), known from fragments, and a few statements from Heraclides of Cyme, which afford evidence on Persian institutions. To these must be added the testimony of the other Greek historians (*e.g.*, Thucydides, Ephorus, Theopompus, with the histories of Alexander) and, before all, that of Xenophon in the *Anabasis* and *Hellenica*. The *Cyropaedia* is a didactic romance, written with a view to Greek institutions and rarely preserving genuine information on the Persian empire. (J. M. M.-R.)

III. HELLENISTIC PERIOD

Alexander's conquest of the whole of the Achaemenid empire cannot be related in detail here. (*See* ALEXANDER III the Great.) The essential fact, however, is that after the victory of Gaugamela and still more completely after the assassination of Darius—avenged, according to the Persian laws, on the perpetrators—Alexander regarded himself as the legitimate head of the Persian empire and therefore adopted the dress and ceremonial of the Persian kings. With the capture of the capitals the Persian war was complete: a truth symbolically expressed in the burning of the palace at Persepolis.

Then began the world conquest—not in the sense of the "world kingdom" concept that subsequent to Alexander grew to comprehend specifically a plan to conquer the Mediterranean shores to the Strait of Gibraltar (the Alexander Romance had the great Macedonian actually accomplishing this feat) but in the more general and accepted sense of the vast Persian empire, whose ruler had become the nearest approach of the orient to its ancient ideal of universal king and whose domain Alexander probably expected to secure and extend. The basis of this new world order was to be the union of Macedonia and Persia, which Alexander began even while campaigning in the east and carried forward upon his return from India. It was in support of this program that the ceremonial of the Persian court, including *proskynesis* (prostration), was adopted by Alexander. This development was readily accepted by the Persians but not by the Macedonians, who, with few exceptions, acquiesced in it only with great reluctance. The union of the two nations was consummated by a great marriage feast at Susa, at which all Alexander's officers, with about 10,000 Macedonians, were married to Persian wives (324 B.C.). The Macedonian veterans were released and the army reorganized, with Persians serving on an equal footing. At this critical juncture Alexander died in Babylon, in June 323 B.C.

The Diadochi.—Alexander left no heir. Consequently his death not only ended the scheme of universal conquest but led to an immediate Macedonian reaction. The Macedonian army, which was considered as representative of the Macedonian people, took over the government under the direction of its generals. The policy of partnership between Macedonians and Persians initiated by Alexander was entirely abandoned; the Persian wives were practically all discarded and the Persian satraps removed, at least from all important provinces. But the attempt to maintain the empire in its unity proved impracticable, and almost immediately there began the embittered war, waged for several decades by the "successors" (Diadochi) for the inheritance of the great king. (*See* HELLENISTIC AGE.)

It was soon obvious that the eastern rulers, at all events, could not dispense with the native element. Peucestas, the governor of Persis, there played the role of Alexander and won the Persians completely to his side, for which he was dismissed by Antigonus Monophthalmus in 316. A similar position was attained by Seleucus—the only one of the Diadochi who had not divorced his Persian wife, Apama—in Babylonia, which he governed from 321 to 316 and regained in the autumn of 312. While Antigonus, who since 316 had striven to win the kingdom of Alexander for himself, was detained by the war with his rivals in the west, Seleucus, with Babylon as his headquarters, conquered the whole of Iran as far as the Indus. In northern Media alone, which lay outside

the main scene of operations and had been only partially subject to the later Achaemenids, the Persian satrap Atropates, appointed by Alexander, maintained his independence and bequeathed his province to his successors. His name is borne by northern Media to the present day (Atropatene, modern Azerbaijan). So, too, in Armenia the Persian dynasty of the Hydarnids held its ground. To these must be added, in the east of Asia Minor, the kingdoms of Pontus and Cappadocia, founded about the end of the 4th century B.C. by the Persians Mithradates and Ariarathes. These states were fragments of the Achaemenid empire which had safely transferred themselves to the Hellenistic state system.

The Seleucids.—The annexation of Iran by Seleucus I Nicator led to a war for the countries on the Indian frontier, Seleucus' opponent being Sandrocottus or Chandragupta (*q.v.*) Maurya, the founder of the great Indian Maurya empire with its capital at Pataliputra (Gr. Palibothra, modern Patna). The result was that Seleucus abandoned to the Indian king not merely the Indian provinces conquered by Alexander but even the frontier districts west of the Indus. As compensation for this cession of imperial territory he received 500 elephants, with other presents (*c.* 303 B.C.). His next expedition was to the west to assist Lysimachus, Ptolemy and Cassander in the overthrow of Antigonus (*qq.v.*).

The battle of Ipsus (*q.v.*), in 301, gave Seleucus Syria and northern Mesopotamia, and from that time he made the Syrian city of Antioch on the Orontes river his residence. Shortly afterward he handed over the provinces east of the Euphrates to his son Antiochus I Soter, who in the following years exercised in the east a very energetic and beneficial activity, which continued the work of his father and gave the new empire and the oriental Hellenistic civilization their form. In his campaigns Alexander had founded several cities in Bactria, Sogdiana and India in which he settled his veterans, and before his death he had begun or planned the foundation of Greek cities in Media and other parts of Iran. These plans were now executed by the Seleucid kings on the largest scale.

Most of the new cities were probably military colonies in the first place and only later evolved to the class of city. They fulfilled strategic needs, serving as a screen against unruly hill tribes within the frontiers of the empire (*e.g.* in Media) or against external enemies. Some, however, were from their foundation truly self-governing Greek cities of the normal type. Of this class may be mentioned Antioch in Persis, founded by settlers from Magnesia in Asia Minor; Alexandria (also known as Charax) at the mouth of the Tigris; Seleucia (*q.v.*) on the Tigris; and Seleucia (Susa; *q.v.*) on the Eulaeus (Karun) river.

Though many of the inhabitants were Asians or people of mixed race, the new colonies preserved their distinctive character as islands of Greek life and influence. The Seleucids counted upon these widely distributed settlements for active support in maintaining their authority in the various regions of their empire. Except in Bactria, where after about 250 B.C. they supported their own dynasty, the Greek settlers did in fact usually identify their interests with those of the Seleucid kings and proved their loyalty. In return for this loyalty they were apparently allowed much freedom in their internal affairs. The degree of control exercised over them by the provincial governors, either satraps or strategi ("generals"), and the variation in this control between one place and another cannot in the absence of sufficient evidence be determined. The new foundations, as had no doubt been envisaged by their founders, greatly aided the growth of commerce throughout the empire and with foreign countries.

Shortly after his conquest of Babylonia, Seleucus Nicator had founded a new capital, Seleucia on the Tigris, his intention being at once to displace the ancient Babylon from its former central position and to replace it by a Greek city. This was followed by a series of other foundations in Mesopotamia, Babylonia and Susiana (Gr. Elymais). "Media," says Polybius (x, 27), "was encircled by a sequence of Greek towns, designed as a barrier against the barbarians." Among those mentioned are Europus (formerly Rhagae) near modern Teheran, Laodicea (? modern Nahavand), Apamea and Heraclea. To these must be added Achaea in Parthia and, farther to the east, Alexandria (Herat) in Aria, Antioch (later Merv) in Margiana (on the site of a destroyed Alexandria) and many others; farther still, Alexandropolis or Alexandria (usually identified with Kandahar) in Arachosia, Alexandria Prophthasia in Drangiana, and the towns founded by Alexander in Bactria, Sogdiana and the mountain country of the Hindu Kush (*see* ALEXANDRIA [cities]).

Thus an active Hellenic life soon arose in the east; Greek settlers must have come in numbers and founded new cities which afterward formed the basis of the Greco-Bactrian kingdom. Journeys of exploration, which were aimed at seeking out and developing new routes for commerce, were undertaken by Seleucid generals in central Asia beyond the Jaxartes (Syr-Darya) river, the northeastern frontier of the empire, and around the shores of the Caspian sea.

While Hellenism was thus gaining some footing throughout the east, the native population remained absolutely passive. Apart from the rude mountain tribes, no national resistance was dreamed of for a long time. The Iranians quietly accepted the foreign yoke, and the higher classes adopted the external forms of the alien civilization even though they actually retained their own characteristics. Eratosthenes, for instance, spoke in high terms of the Iranians, ranking them (as well as the Indians, Romans and Carthaginians) on a level with the Greeks in their capacity for adopting city civilization. The later Parsee tradition contends that Alexander burned the sacred books of Zoroaster, the Avesta, and that only a few fragments were saved and afterward reconstructed by the Arsacids and Sassanids. This however is absolutely unhistorical. The Persian religion was never attacked by the Macedonians and Greeks. Under their dominion, on the contrary, it expanded with great vigour, not only in the west (Armenia, north Syria and Asia Minor, where it was the official religion of the kings of Pontus and Cappadocia) but also in the east, in the countries of the Indian frontier. That the pre-Zoroastrian gods—Mithra, Anahita (Gr. Anaitis), etc.—had come to the forefront has been mentioned above. This movement, however, was void of all national character and ran on precisely the same lines as the movement in the Syrian, Jewish and Egyptian cults. Only in Persis itself did the national character of the religion survive side by side with the memory of the old Persian empire; there a local Persian dynasty continued to rule in the centre of the province at Istakhr (*see* PERSIS).

Decline of the Seleucids.—The gigantic empire conquered by Seleucus I, stretching from the Aegean sea to India, was not easy to control, and everywhere it offered points of attack to external enemies. The wars which the Seleucid kings of the 3rd century B.C. had to fight with their Ptolemaic rivals in Egypt and with lesser states such as Galatia and Pergamum inevitably had repercussions in the eastern regions of their empire, the more so since the vast empire with its many races held together only in a loose administrative framework was always threatening to break apart. The borders of Iran were severely affected. In Parthia two brothers, Arsaces and Tiridates, revolted against their Seleucid satrap and founded an independent kingdom and the Parthian era, beginning in 247 B.C. In vain did Seleucus II toward the end of his reign (228 B.C.) attempt to suppress the new state. The Bactrian Greeks had established an independent state at about the same time.

At the accession of Antiochus III (223 B.C.) the greater part of Iran was, however precariously, still in Seleucid hands. In 220 Antiochus suppressed an insurrection of the satraps of Media and Persis. Ten years later he led a great expedition into the eastern provinces with the purpose of restoring the imperial authority in its full extent. Media was reduced to order (210), and successful campaigns were waged against the Parthians (209) and against Euthydemus, king of Bactria (208–206). In spite of his successes Antiochus concluded peace with both kingdoms, rightly considering that it would be impossible to retain these remote frontier provinces permanently. He next made a pact of friendship with the Indian king Sophagasenus (Subhagasena; 206), then returned by way of the southern provinces—Arachosia, Drangiana, Carmania and Persis—to Babylonia, which he reached in 205 or 204. This great expedition had fully re-established the Seleucid do-

minion in Iran and its border lands. But Antiochus' defeat by the Romans in 190/189 B.C., with the resultant loss of territory in Asia Minor and the heavy war indemnity imposed, enfeebled the rest of his empire. In order to raise money he plundered a wealthy temple of Bel in Elymais but was killed by the inhabitants (187). His presence in Elymais suggests that he had decided to undertake new measures to strengthen his hold on the eastern provinces.

The governors of Armenia now asserted their independence. Artaxias founded the kingdom of Greater Armenia and Zariadres the kingdom of Sophene on the Euphrates and the source of the Tigris. In other districts rebellions also occurred; and in the east the Bactrian kings, Euthydemus and his successors, began to conquer the eastern Iranian provinces (Arachosia, Aria, etc.) which were still nominally Seleucid. (*See* BACTRIA; DEMETRIUS [king of Bactria]; EUCRATIDES; EUTHYDEMUS.)

Antiochus IV Epiphanes (175–163 B.C.) restored once more (at least in part) the eastern dominion. He defeated Artaxias of Armenia, restored several towns in Babylonia and subdued the Elymaeans. Persis, also, and Media were still subject to him. He tried to strengthen Hellenism throughout his empire by settling Greek colonists and mercenaries in the native towns and granting them the status of Greek cities. But his premature death at Gabae (Isfahan) in Persis prevented his achieving his next aim: the conquest of Parthia and the reincorporation within the Seleucid empire of the independent Bactrian state in east Iran. In 161/160 Demetrius I Soter (162–150 B.C.) suppressed the revolt in Media and Babylonia of Timarchus, the governor of the upper satrapies. During his reign the Seleucid empire still embraced those provinces and perhaps also Persis. *See* also ANTIOCHUS; SELEUCID DYNASTY. (R. H. Si.)

IV. PARTHIAN EMPIRE, 2ND CENTURY B.C.–3RD CENTURY A.D.

Arsacids.—Meanwhile, in the east, the Parthian Arsacids had begun their expansion (*see* ARSACES). Phraates I (*q.v.*; *c.* 176–171 B.C.) subdued the Mardians in the Elburz mountains. His brother Mithradates I (*q.v.*, *c.* 171–*c.* 138 B.C.) had to sustain a difficult war with Eucratides of Bactria, but eventually succeeded in wresting from him the districts of Tapuria and Traxiana which lay in the vicinity of Tus and Meshed. However the tradition that Mithradates advanced eastward beyond the Indus depends only on a doubtful interpretation of a passage in Orosius. In the west he conquered Media and invaded Babylonia. Though in 140 the Seleucid king Demetrius II Nicator took the field in order to save the east, the latter was defeated and captured. Mithradates next reduced the province of Elymais, according to Strabo and Justin, sacking an important temple of Artemis in the mountains, and capturing the Greek city of Seleucia on the Hedyphon (Surraq, near Behbehan in southwest Iran). His son Phraates II (*c.* 138–128) was attacked in 130 by Antiochus VII Sidetes, brother of Demetrius II, whom Phraates promptly released. Antiochus advanced and once more recovered Babylonia, but was defeated during 129 in Media, and fell in a desperate struggle. With this battle Seleucid dominion over the countries east of the Euphrates was finally lost. The Babylonian towns, especially Seleucia, were handed over by Phraates to the Hyrcanian Himerus, who punished them severely for their resistance.

TABLE I.—*Arsacid* (*Parthian*) *Kings*

Name	Reign years	Name	Reign years
Arsaces	*c.* 250/247 B.C.–?	Orodes III	A.D. 4–*c.* 6/7
Tiridates I	?–*c.* 211	Vonones I	7/8–12
Artabanus I	*c.* 211–191	Artabanus III	12–*c.* 38
Priapatius	*c.* 191–176	Tiridates III	*c.* 36
Phraates I	*c.* 176–171	Cinnamus	*c.* 37
Mithradates I	*c.* 171–138/137	Gotarzes II	39 or 44–51
Phraates II	*c.* 138–128	Vardanes	*c.* 39–47/48
Artabanus II	*c.* 128–124/123	Vonones II	*c.* 51
Mithradates II	*c.* 123–*c.* 87	Vologaeses I	51/52–79/80
Gotarzes I	91–81/80	Pacorus II	78–115/116?
Orodes I	80–77/76	Artabanus IV	80–81
Sanatruces	..77/76–70 or 69	Osroes	*c.* 109/110–128/129
Phraates III	70 or 69–58/57	Parthamaspates	*c.* 117
Mithradates III	56–55	Vologaeses II	105/106?–147
Orodes II	*c.* 57–37	Mithradates IV	128/129?–147?
Pacorus I	d. 38	Vologaeses III	148–192
Phraates IV	*c.* 38–*c.* 32	Vologaeses IV	191–208/209
Tiridates II	*c.* 30–25	Vologaeses V	208/209–228/229
Phraataces (Phraates V)	2 B.C.–A.D. 4	Artavasdes	212/213–224
			c. 228

In 140 the Seleucid king Demetrius II Nicator took the field in order to save the east, the latter was defeated and captured. Mithradates next reduced the province of Elymais, according to Strabo and Justin, sacking an important temple of Artemis in the mountains, and capturing the Greek city of Seleucia on the Hedyphon (Surraq, near Behbehan in southwest Iran). His son Phraates II (*c.* 138–128) was attacked in 130 by Antiochus VII Sidetes, brother of Demetrius II, whom Phraates promptly released. Antiochus advanced and once more recovered Babylonia, but was defeated during 129 in Media, and fell in a desperate struggle. With this battle Seleucid dominion over the countries east of the Euphrates

During these wars great changes had taken place in eastern Iran. Powerful nomadic tribes, the Sacae and the Tochari (or Tukharians, called Yue-chi [*q.v.*] by Chinese writers), forced their way into Sogdiana, and about 130 overran Bactria. From Bactria they began to advance farther into Iran and India. Phraates II marched to encounter them. He pressed into service Greek prisoners from the army of Antiochus, but these deserted him in the battle. Phraates was defeated and slain, while his country was extensively ravaged. His successor was Artabanus II (also numbered I; *c.* 128–124/123), the uncle of Phraates, who likewise fell in battle against the Tochari; but his son Mithradates II, called the Great (*c.* 123–*c.* 87), apparently defeating the Scythians, restored for a while the power of the Arsacids. He also defeated Artavasdes, king of Greater Armenia, whose son Tigranes (*q.v.*) became a hostage in Parthian hands, and was redeemed, as Strabo related, only for the cession of 70 valleys. Tigranes subsequently attempted to seize Cappadocia, and the Roman praetor L. Cornelius Sulla advanced against him. In 92 B.C. Mithradates, whose forces were also advancing into north Syria against the declining Seleucids, concluded the first treaty between Parthia and Rome.

Meanwhile a prominent Parthian, Gotarzes, named as satrap of satraps in the Greek inscription at Bisitun, was establishing himself as an independent monarch in Babylonia. Mithradates still controlled Iran and northern Mesopotamia until his death (not before 87 B.C.), after which, profiting from the division of the Parthian kingdom, Tigranes of Armenia extended his power and assumed the dignity of "great king." Soon, however, a son of Mithradates II, Orodes I, had risen in Iran to assert his hereditary right against Gotarzes. Cuneiform tablets show that by 80 B.C. Orodes had replaced Gotarzes in Babylonia. His reign was brief. It was followed by the period of the famous "campaign coins" which, exceptionally, bear mint names Rhagae (Ray), Traxiana, Margiana, Aria and an inscription in Greek meaning "on an expedition." They seem to attest a reconquest of territory from Orodes, though whether by a Gotarzes returned to power or by an "unknown king" is still disputed. This period of confusion came to an end when in 77 B.C. the octogenarian king Sanatruces was set on the Parthian throne by the central Asian tribe of the Sacaraucae. Yet it was not until Sanatruces' successor, Phraates III (*c.* 70–*c.* 57), that the kingdom was once again in a completely settled state.

Organization.—The Parthian empire as founded by the conquests of Mithradates I and restored first by Mithradates II, and again by Phraates III, was in many of its outward forms a revival of the Achaemenid empire. Thus the Arsacids began to assume the old title "king of kings," though previously their coins had, as a rule, borne only the legend "great king." As will be seen, their script was directly derived from the Aramaic of the Achaemenid chancery.

Meanwhile, as successors to a Greek administration in one province after another, the Parthians assimilated Greek government practice, and, in addition to their own ideographically written language (described below), for many purposes made use of Greek (*e.g.*, on their coinage), while there are several reports of Parthian rulers who understood spoken Greek. In reality, however, the Parthian empire was radically different in structure from its predecessors. Instead of aiming at direct, centralized government of its territories, it was an early example of a feudal type of organization, in which the greater part of the empire was governed on behalf of the "king of kings" by vassal princes belonging to hereditary local dynasties. Thus the direct possessions of the kings —provinces governed by their satraps—consisted of a rather narrow strip of land, stretching from the Euphrates and north Babylonia through southern Media and Parthia as far as Arachosia (in southeastern Afghanistan). In addition to the vassal states, there were also a number of Greek cities of Seleucid foundation which retained some degree of local autonomy within the royal provinces and the states of the vassal kings. Nicephorium, Anthemusia,

Ichnae, Artemita and Chala are all mentioned as Greek cities in Mesopotamia, but by far the most important of the autonomous cities was Seleucia on the Tigris. The documents of the royal administration were often dated according to the Arsacid era, which commenced in 247 B.C. In contrast the Greek cities continued to date by the Seleucid era, which in the Babylonian reckoning commenced in 311 B.C. (used for instance on the Parthian tetradrachma coinage minted at Seleucia), or with a double dating referring to both eras.

Topography of the Parthian Empire.—The main axis of the empire lay along the principal trade route running from west to east, but in the 1st century B.C. there was a shift in the centre of gravity of the Parthian kingdom from the northeast to the plains of Mesopotamia. This was no doubt the result of pressure in the east from the nomadic central Asian tribes. Thereafter the capital of the empire was generally at Ctesiphon (*q.v.*), the Parthian suburb opposite Seleucia on the east bank of the Tigris, the two forming a twin city. It is noteworthy that the mint for the Parthian royal tetradrachma coinage seems always to have remained at Seleucia.

To the west, on the Euphrates, excavations at the Parthian frontier post of Doura-Europus (*q.v.*) have revealed many notable finds. Between Doura and the Tigris lay Hatra (Arabic Al Hadr), a frontier fortress held by Arab allies of Parthia, and also the site of important excavations by the Iraq government. Eastward of the capital lay Artemita, and farther along the eastward route lay Kangavar, a town which still exists and was in Parthian times the site of a temple of Artemis (Anahita) of which traces survive. Ecbatana (Hamadan) seems to have retained its importance under the Parthians.

An important centre farther east was Rhagae (Ray), of which the ruins are situated a few miles southeast of the modern capital of Iran at Teheran. Eastward again from Rhagae were the districts of Choarene and Comisene. In the latter district Polybius describes an important city and early Parthian capital at Hecatompylos, thought to be in the neighbourhood of modern Damghan, though the site has not been identified on the ground. Near Hecatompylos was a mighty castle, Tagae, sometimes identified with the medieval stronghold of Girdkuh, rather than the site northeast of Damghan known as Taq.

Not far from this point the main route crossed to the north of the Elburz range into Hyrcania (Gorgan province). Here the provincial capital was Zadracarta; this site may be marked by the findspot of the Hellenistic inscription near Asterabad (Gorgan). In the same province are mentioned the towns of Tambrax and Syrinx, of uncertain location.

The next district was Astavene (Ustawa), with its chief city Asaak (apparently in the vicinity of modern Quchan) where Arsaces, the first Parthian king, was proclaimed. There a perpetual fire was reverenced. Farther to the northeast was the district of Parthyene, with its capital city Mithradatkert (Nisa), near to the modern Ashkhabad, the scene of important Soviet excavations. Then followed Apavarcticene (Abivard) and Margiana (the district of Merv).

Southward of Merv, following the Royal road, lay the province of Aria (Herat), with its two cities of Artacavana and Alexandria of the Arians. Beyond these to the southwest came the territory of Anauon, in which lay the cities of Farah, Bust and Neh, all of which still retain their names in virtually the same forms as in Parthian times. There followed the districts of Drangiana, Sakastan (Sanskrit Sakasthana, known also as Paraetacena) and Arachosia, the latter comprising the modern province of Kandahar. These eastern provinces were only for limited periods subject to the central government of the Parthian king. During the 1st century A.D. they appear to have formed part of the independent Indo-Parthian kingdom, with its best-known centre at Taxila in West Pakistan.

Vassal States.—The royal provinces were surrounded to the south by a ring of minor states, which as a rule were dependent on the Arsacids, though occasionally transferring their allegiance on the rise of a new power, such as that of Tigranes of Armenia, or a Roman invasion. Of the vassal kingdoms, only Characene, Elymais and Persis together with some of the city-states, such as Hatra and Seleucia, were permitted to issue coinage while under Parthian control. The most important of the Parthian vassal states were the following:

1. The kingdom of Osroene (*q.v.*) in the northwest of Mesopotamia, with Edessa as capital.

2. The desert of Mesopotamia, which came to be known in Parthian as Arabistan, after its population of Arab tribes under the rule of chiefs. One of these, Alchaudonius, became prominent in the period of Tigranes and Crassus. According to Plutarch and Pliny the former encouraged the Arabs to settle in Mesopotamia. In the 2nd and 3rd centuries A.D. the Arab city of Hatra in this region became an important Parthian frontier fortress, governed by its own dynasty, of Aramaic origin.

3 and 4. To the east of the Tigris two kingdoms, Gordyene (Cordyene), the country of the Carduchians, a mountainous district south of Armenia; and Adiabene (Hadyab), the ancient Assyria, with its metropolis at Arbela (Irbil; *q.v.*), situated on either side of the Zab river.

5. On the farther side of the Zagros mountains, adjoining Adiabene to the east, the kingdom of Atropatene in north Media,

THE PARTHIAN EMPIRE

the name of which is preserved in the modern Azerbaijan. By the ancient writers this kingdom was often referred to simply as Media (*q.v.*).

While the power of Armenia was at its height under Tigranes in the 1st century B.C., all these states acknowledged his rule. After the victories of Pompey, however, the Romans claimed the suzerainty, and during the expeditions of Crassus and Mark Antony they oscillated between Rome and Parthia, though their inclination was generally to the latter.

6. In the south of Babylonia, in the district of Mesene (Persian Meshan), on the fall of Antiochus VII Sidetes in 129 B.C. a local prince, Hyspaosines or Spasines, son of Sagdodonacus, founded a kingdom which survived until the rise of the Sasanian empire. In a cuneiform inscription of 127, on a clay tablet dated after that year, he is called Aspasine. A town originally founded by Alexander near the junction of the Eulaeus (Karun) with the Tigris was refortified with dikes by Spasines and became known as Spasinu Charax ("the fort of Spasines"), or, in Pliny, simply Charax. In the following centuries it was the main mercantile centre on the Tigris estuary, but the site has not been precisely located in modern times.

This kingdom of Mesene, also called Characene, is known from occasional references in various authors, especially Lucian. The chief source of information, however, is to be found in the numerous coins of the dynasty, to which a large find of coins from Basra brought important accessions. The coins are dated according to the Seleucid era and make it possible to compile the following fairly complete list of the local kings:

Hyspaosines (127–*c.* 121 B.C.)	Abinerglus (*c.* A.D. 10–*c.* 13)
Apodacus (*c.* 109–*c.* 105)	Adinerglus (*c.* 22)
Tiraeus I (*c.* 90–*c.* 89)	Attambelus III (*c.* 38–*c.* 44)
Tiraeus II (*c.* 78–*c.* 48)	Thionesius II (*c.* 46)
Artabazus (48–47)	Thionesius III (*c.* 52)
Attambelus I (*c.* 46–*c.* 28)	Attambelus IV (*c.* 54–64)
Thionesius I (*c.* 20)	Attambelus V (*c.* 73)
Attambelus II (*c.* 17 B.C.–*c.* A.D. 8)	Attambelus VI (*c.* 104–*c.* 105)
	Thionesius IV (*c.* 111–*c.* 112)

7. East of the Tigris lay the kingdom of Elymais (Elam), to which belonged Susa and its modern representative Ahvaz, farther down on the Karun. The heart of the kingdom lay not at Susa, however, which seems to have fallen into Parthian hands and to have been administered by a Parthian satrap, but close under the mountains of Luristan near Behbehan and Izeh (formerly called Malamir), where the local dynasty has left rock reliefs and inscriptions in a form of Aramaic. The monuments of Tang-e Sarvak, north of Behbehan, which relate to a King Orodes of this dynasty, were studied in detail by W. B. Henning. The dynasty seems to have been founded by a ruler named Kamnaskires, known from coins dated 81 B.C. The coinage of another Orodes, who reigned shortly after A.D. 59, displays Aramaic script. The kingdom, though seldom mentioned, survived until its extinction by Ardashir I.

8. In the district of Persis (*q.v.*), the local dynasts became independent in the time of Antiochus IV, and on their coins appear as zealous adherents of Zoroastrianism and the fire cult. These coins bear inscriptions in the Persian language but written ideographically with Aramaic characters. They were forced, however, to acknowledge the suzerainty of Parthia, to which they stood in the same position as the Persians under the forefathers of Cyrus had stood to the Medes. Later, before the foundation of the Sassanid power, Persis disintegrated into a number of small local states. Even in Carmania (Kerman) there were independent kings.

9. The east of Iran was never subject to the Arsacids. In Arachosia and the Punjab, however, there appears in the 1st century A.D. an independent dynasty with Iranian and indeed peculiarly Parthian names. This was the Indo-Parthian dynasty. Its best-known representative, Gondophares (*q.v.*), reigned over Arachosia and the Indus district from *c.* A.D. 19 to 45. According to a legend which may contain a substantial core of historical truth, it was under Gondophares that the apostle Thomas visited northern India to preach there. A vivid picture of life in Taxila under the Indo-Parthians is also given by Philostratus in his *Life of Apollonius of Tyana*, which describes in somewhat legendary terms a visit to that city of the sage Apollonius. Apollonius reached Taxila after visiting the Parthian capital in the third year of Vardanes I (A.D. 42/43), and having resided there for at least one year and four months; other indications suggest that Apollonius was in Taxila in A.D. 49. There is a description of the Indo-Parthian "satrap of the Indus," presumably one of the satraps of Chukhsha known from inscriptions, who was corresponding cordially with the Parthian king in the tone not of a vassal but of the representative of a fully independent power, an impression that is likely to be historical. It was the Kushan invasion of the Indo-Parthian empire in the second half of the 1st century A.D. which brought about its downfall. This event may have occurred around A.D. 78, and approximately contemporary is the reference in the anonymous *Periplus of the Erythraean Sea* to Parthian princes at Minnagar in the Indus delta (an unlocated site) "continually expelling one another."

Remains of the Parthian Language.—Knowledge of the history and culture of the Parthian empire is largely based on descriptions given by Greek and Latin authors. Research in the 20th century, however, has made available an increasing body of material relating to the language employed by the Parthians themselves. The speech of the nomadic founders of the Parthian state, the Parni and Dahae, was described by Justin as "halfway between Scythian and Median, and a mixture of both." They seem, however, to have adopted the speech of the original Iranian inhabitants of Parthia (Parthava), and the language subsequently attested as Parthian is a standard north Iranian dialect. Until the middle of the 1st century B.C. it retained unvoiced consonants between vowels, together with the other characteristics of an Old Iranian dialect. Later came the transition into the Middle Iranian phase. To this Middle Iranian dialect, however, a peculiar writing system was applied, that which in later times was called Pahlavi, meaning "Parthian." In modern usage, however, the term Pahlavi is specifically applied to the form of writing used by the Sasanians (*see* PAHLAVI LANGUAGE), the term Parthian being reserved for the earlier form. The script was a derivative of Achaemenid chancery Aramaic, and in the writing of many common Iranian words the Aramaic equivalent was written to represent the root but with the addition of the terminations proper not to the Aramaic but to the Iranian dialect itself. The resulting hybrid forms were simply pronounced as Iranian. With the passage of time the proportion of Aramaic ideograms diminished and that of Iranian phonetic spellings increased, this process evidencing the gradual falling out of use of the Aramaic language in Iran.

Among the earliest monuments of this ideographically written Parthian language are the ostraca discovered in Soviet excavations at Nisa, a site named Mithradatkert after its Parthian founder in ancient times. It is situated not far from Ashkhabad in the Turkmen S.S.R. Also in ideographically written Parthian is one of the three parchments found at Avroman (Owraman) in Kurdistan and dated to A.D. 53, the other two being in Greek and dating from the 1st century B.C. Apart from these the extant texts in ideographic Parthian are limited to a small number of minor inscriptions and to the Parthian texts of the bilingual and trilingual Sasanian inscriptions, discussed below.

There exist, however, a considerable number of texts in Parthian dialect, written phonetically in a form of the Syriac script, among the Manichaean documents recovered by expeditions from central Asia. The work of piecing together these fragmentary manuscripts was carried on over many years by F. Andreas, F. Müller, C. Salemann, W. B. Henning, M. Boyce and others. From this material a considerable body of linguistic evidence was brought together, which greatly extended knowledge of the spoken forms of Parthian and contributed to the interpretation of the more difficult texts in ideographic writing.

Besides these written texts, there is substantial evidence of the existence among the Parthians of an extensive literature of oral poetry, recited by minstrels, notably at the courts of kings and nobles. This poetry, mainly devoted to heroic subjects, seems to have been composed, unlike the later Islamic Persian verse, in stressed rather than syllabic metre and without the use of rhyme,

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

PERSIAN COINS: (TOP) SIGLOS OF DARIUS; (SECOND) TETRADRACHMA OF THE SATRAP TISSAPHERNES; (THIRD) TETRADRACHMA OF MITHRADATES II OF PARTHIA; (BOTTOM) DRACHMA OF SHAPUR I [ENLARGED]

an Arabic innovation. It is reflected, though in reworked form, in Gurgani's poem *Vis u Ramin*, and in the episode of Godarz in the *Shah-nama* of Firdausi; also more directly in the *Yadgar i Zareran*, a Middle Persian poem in the Pahlavi script. Though apparently of great richness and extent, this Parthian minstrel poetry was rarely set down in the cumbrous ideographic script and has otherwise almost entirely perished.

Cultural Elements in the Parthian Empire.—Three national elements of widely differing kinds contributed to the origin of the Parthian empire. On the one hand the state sprang from a predatory nomad tribe, the Scythian Dahae, which had established itself in Khurasan, on the borders of civilization, and gradually annexed further districts as the political situation or the weakness of its neighbours allowed. Consequently these nomads were the main pillar of the empire, and from them appear to have derived the great magnates, with their huge estates and hosts of serfs, who composed the imperial council, led the armies, governed the provinces and made and unmade the kings.

The military organization was nomadic in character and was made up of two arms. First the heavy cavalry (cataphracti), in which the rider and often even the horse were fully protected in armour of steel scales. These were armed with the great lance (contus) and employed shock tactics to break an enemy line. The heavy cavalry with their elaborate equipment were recruited mainly from the wealthier retainers of the nobles and composed the bodyguard of the generals—for example that of Surenas (the Suren, a Parthian hereditary title) on the occasion of the Roman defeat at Carrhae (53 B.C.). The mass of the Parthian cavalry, however, was composed of horse archers, less heavily armoured but of legendary equestrian skill and mobility. From these is derived the familiar picture of the Parthian horseman shooting over his shoulder as he retires.

The importance of the nomadic element in the Parthian empire is obvious from the fact that in the civil wars the deposed kings consistently took refuge among the Scythian Dahae and were restored by them. Yet in Parthia these nomads became assimilated to the local peasantry and came to adopt their dress and manners as well as their religion. Even the kings, after the first two or three, wore their hair and beards long after the Iranian fashion, whereas their predecessors were beardless.

Unlike the Achaemenians and the Sassanids, the Arsacids seem to have lacked any strong religious conviction; yet they appear to have acknowledged at the same time the old Iranian gods and the leading tenets of the Zoroastrian fire cult. They erected fire altars and, according to Justin, obeyed the commandment to abandon all corpses to the dogs and fowls. At the same time archaeological excavation both at Susa and in Soviet territory suggests that inhumation burial in sarcophagi of terra cotta continued to be practised in Iran under Parthian rule, at least among the subject populations. The union recommended by the Zoroastrian creed between brother and sister—and even son and mother—occurred among the Parthians. And besides the council of the nobility there was, according to Strabo, a second council of "Magians and wise men."

At the same time, the dominant world culture of Hellenism had also penetrated Parthia and Media. Parthia was indeed the successor state of the Seleucid empire, and some acquaintance with Hellenic culture was indispensable to every state which hoped to play a part in world affairs and was not so utterly secluded as Persis and Atropatene. Moreover the Arsacids lacked any strong cultural tradition of their own. Many of their institutions were borrowed from the Seleucid empire—their coinage with its Greek inscriptions, its nomenclature and Attic weight standard, and in all probability much of their administrative practice also. In the towns many Greek merchants were settled. The first Mithradates himself assumed, after his great conquests, the title Philbellene, "friend of the Greeks," which was retained by many of his successors. There follow the surnames Epiphanes, "(God) Manifest"; Dikaios, "the Just"; and Euergetes, "the Benefactor." All these were essentially Greek in their reference and were regularly borne by the Parthian kings. Orodes I spoke good Greek, and Greek tragedies were staged at his court, as Plutarch relates.

It was not until the 1st century A.D. that Greek influence began to weaken. The Greek script of the chanceries in Media and Babylonia was replaced by Parthian, as can be seen from the third of the Avroman parchments. The Hellenistic character of the coinage succumbed to a process of conventionalization, and as the Greek coin inscriptions become increasingly illegible the name of the king is in several cases indicated by Parthian inscriptions, usually in the form of abbreviations. This decline of Parthian Hellenism can naturally be associated with the seven-year revolt of Seleucia from the royal authority between A.D. 35 and 42. The city was finally brought to terms by Vardanes. Subsequently Vologaeses I (*q.v.*; A.D. 51/52–79/80) founded nearby in the district of Nahr Malka (*i.e.*, of the royal canal, which joined the Euphrates to the Tigris near Seleucia) the city of Vologesias or Balashabad. The new city took over much of the commercial prosperity of the old, and from this moment the influence of Babylonian Hellenism was greatly reduced.

Wars With Rome.—The feudal and decentralized structure of the Parthian empire may help to explain why, though founded on annexation and perpetually menaced by hostile armies both in the east and the west, it never took a strong offensive after the days of Mithradates II. It was bound to protect itself against

attack both from the Scythians in the east and from the Romans in the west. To maintain or regain suzerainty over Mesopotamia and the vassal states of that region, as also over Atropatene and Armenia, was the imperative task. Parthia thus tended to remain on the defensive and even in this role was often lacking in energy. Whenever it made an effort to enforce its claims, it retreated as soon as confronted by a resolute foe.

The wars between Parthia and Rome therefore were initiated not by the Parthians—deeply injured though they were by the encroachments of Pompey—but by Rome itself. Rome felt itself obliged, reluctantly enough, to enter upon the inheritance of Alexander the Great, and since the time of Pompey had been subjecting the Hellenistic countries as far as the Euphrates. The task now faced the Romans of annexing the remainder of the Seleucid empire, which had covered the whole east from the Euphrates to the Indus, and thus of saving Greek civilization (as is argued by Plutarch in his comparison of Nicias and Crassus). The aristocratic republic quailed before such an enterprise, though Lucullus at the height of his success entertained the thought. However the ambitious men whose goal was to erect their own sovereignty on the ruins of the republic took up the project. With this objective M. Licinius Crassus, the triumvir, in 54 B.C. took the offensive against Parthia, the occasion being favourable because of dynastic troubles between Orodes II, the son of Phraates III, and his brother Mithradates III. The Roman infantry proved incapable of countering in open country the cavalry tactics of the Parthians; Crassus' forces were reduced to the last extremity, and he met his death at a parley, allegedly by treachery (June 9, 53 B.C.), after his army was routed at Carrhae. After this battle Mesopotamia was regained by the Parthians, and King Artavasdes of Armenia entered their alliance. But apart from the ravaging of Syria (51 B.C.) by Pacorus, the son of Orodes, the threatened attack on the Roman empire materialized neither then nor during the civil war of Caesar and Pompey.

At the time of his assassination Caesar was intent on resuming the expedition of Crassus. The Parthians formed a league with Brutus and Cassius, as previously with Pompey, but gave them no support until in 40 B.C. a Parthian army led by Pacorus and the republican general Q. Labienus harried Syria and Asia Minor. It was repulsed by Publius Ventidius, Mark Antony's lieutenant, and Pacorus himself fell on June 9, 38 B.C., at Gindarus in northern Syria. Antony then attacked the Parthians in 36 B.C. and penetrated through Armenia into Atropatene, but was defeated by Phraates IV—who in 37 B.C. had murdered his father, Orodes II—and compelled to retreat with heavy losses. The continuation of the war was frustrated by the conflict with Octavian. Armenia alone was subdued in 34 B.C. by Antony, who treacherously captured and executed King Artavasdes.

Roman Settlement.—That the Romans expected Augustus to take up the work of his predecessors, annihilate the Parthian dominion and subdue the east as far as the Indians, Bactrians and Seres is clear from Virgil, Horace and the other Augustan poets. Augustus, however, disappointed these expectations, since his whole policy and the needs of the newly organized Roman empire demanded peace. His efforts were devoted to reaching a *modus vivendi* by which the authority of Rome and its most vital claims might be peacefully vindicated. This the weakness of Parthia enabled him to do without much difficulty. His endeavours were assisted by the revolt of Tiridates II (*q.v.*), before whom Phraates IV was compelled to flee (32 B.C.) until he was restored by the Scythians. Augustus lent no support to Tiridates in his second march on Ctesiphon in 26 B.C., and Phraates was all the more inclined on that account to stand on good terms with him. Consequently in 20 B.C. he restored the standards captured in the victories over Crassus and Antony and recognized Roman suzerainty over Osroene and Armenia. In return the Parthian dominion in Babylonia and the other vassal states was left undisputed.

Shortly after the restoration of the standards in 20 B.C. Augustus sent as a present to Phraates IV an Italian slave girl named Musa, by whom Phraates had a son, Phraataces, known later as Phraates V. Subsequently Musa persuaded her husband to send his older children to Rome, where they remained as hostages to Augustus. In 2 B.C. Musa secured the throne for her son by poisoning Phraates IV, and in A.D. 2 she and Phraataces were married, an event which horrified the Greeks and Romans but which is no doubt an example of the kin marriages advocated by the Magi and apparently adopted in this period, as later under the Sasanians, by the Iranian people in general. The portrait of Musa appears with that of Phraataces on the coinage at this time. In A.D. 4, however, Phraataces was driven into exile and died soon afterward. The Parthians then obtained the release of the eldest of the princes interned at Rome, Vonones I (*q.v.*), but his foreign manners and dependence on Rome soon caused them to call in another Arsacid, Artabanus III (*see* ARTABANUS), known chiefly for his letter of Dec. A.D. 21 to the magistrates and city of Susa, the only Arsacid royal document which has been preserved. His reign was interrupted *c.* A.D. 36 by another Roman nominee, Tiridates III, whose rule was of short duration.

Decline of Parthia.—The close of the reign of Artabanus III (*c.* A.D. 38) was followed by the rebellion of Seleucia, which lasted for seven years, and by a period of civil war between Gotarzes II, whose power was centred in Hyrcania, and Vardanes, who seems to have controlled Babylonia. These ended only with the assassination of Vardanes in A.D. 47/48. Another pretender to the throne, the Roman nominee Meherdates, was defeated and captured by Gotarzes, whose own death followed in A.D. 51. Further conflict with Rome broke out under Vologaeses (Volagases) I (reigned 51/52–79/80), who made his brother Tiridates king of Armenia. After a long war, described by Tacitus, in which the Roman army was commanded by G. Domitius Corbulo, peace was concluded in 63, confirming Roman suzerainty over Armenia but recognizing Tiridates as king (*see* CORBULO, GNAEUS DOMITIUS). Tiridates himself visited Rome and was invested with the diadem by Nero (66). After that Armenia continued under the rule of an Arsacid dynasty. During this fighting Vologaeses was diverted by attacks on his eastern frontier in Hyrcania. "Hyrcanian" emissaries even visited Corbulo, and if Tacitus is correct in saying that they returned home by way of the Indian ocean, they must have been representatives of the Kushan power, which in this period was expanding to the detriment of the eastern frontiers of Parthia. Later the Alans (Alani), a great Iranian tribe of south Russia, broke for the first time through the Caucasus passes and ravaged Media and Armenia.

After the reign of Vologaeses I came a period of great disturbances in the history of Parthia. A continuous narrative is lacking, but the evidence of coins, added to that of isolated literary references, shows that at certain periods there were two or more kings reigning concurrently. One of the best-known episodes was the invasion of Parthia by the Roman emperor Trajan. With the Parthian kingdom divided between Osroes, Vologaeses II and perhaps also Pacorus II, the Romans were able to march down the Euphrates, haul their fleet across to the Tigris and occupy Ctesiphon unopposed (115). Trajan then sailed down the Tigris to the Persian gulf, receiving on the way the submission of the king of Characene, and is even said to have contemplated an expedition to India. However he returned to Babylon in 116 to learn that the greater part of the conquered territory was in revolt. Though he encompassed the death of the Parthian prince Sanatruces by embroiling him with his cousin Parthamaspates, Trajan's position was untenable, and in 117 he retreated up the Tigris, evacuating Parthian territory after a fruitless siege of the desert fortress of Hatra. Hadrian, who succeeded him in the same year, favoured a peaceful settlement of the Parthian problem.

In 161 Vologaeses III invaded Cappadocia and Syria; as a consequence a powerful Roman expedition was sent to the east under Lucius Verus, the colleague of Marcus Aurelius, and the general Avidius Cassius. In 165 the latter led the legions into Parthian territory, capturing Doura-Europus and reaching and storming Ctesiphon, but was forced to evacuate the Parthian capital by an outbreak of smallpox. Subsequently sporadic fighting in Mesopotamia and Armenia led to further reductions of Parthian influence. Septimius Severus also campaigned on the Parthian frontier, but it was not until 198 that he penetrated deep into Parthian territory, occupying Seleucia and Babylon, while Ctesiphon was

taken by storm and sacked. On his return march Septimius Severus, like Trajan, failed to capture Hatra.

These repeated invasions appear to have crippled the Parthian kingdom. Vologaeses IV was succeeded in 208/209 by his son of the same name; yet from 212/213 the latter was obliged to share his kingdom with a rival, Artabanus (Ardavan) V, whose control of Susa in 215 is attested by an inscription discovered at that site. Meanwhile the dated coinage of Seleucia continued until 228/229 with the types of Vologaeses V. The Roman emperor Caracalla was not the only one to exploit the weakness of the Arsacids by an invasion of Media. In southern Iran the new dynasty of the Sasanians was gathering strength, and by 226/227 Ardashir had overthrown both the Arsacid princes, leaving only Artavasdes (Ardavazd), the son of Artabanus, to carry on a hopeless struggle for a few years in the mountains of Azerbaijan.

V. SASANIAN EMPIRE, *c.* A.D. 224–651

Rise of Ardashir I.—At the beginning of the 3rd century A.D. the Arsacid empire had been in existence for 400 years. It had been undermined, however, by repeated Roman invasions, and the kingdom was once more divided, this time between Vologaeses V, who seems to have ruled at Ctesiphon, and Artabanus V, who controlled Iran, and whose authority at Susa is attested by an inscription of A.D. 215. The moment was thus ripe for the overthrow of the Arsacids, and it was against Artabanus V that the blow eventually fell.

On his borders there arose in Persis (Fars)—just as Cyrus had arisen against Astyages the Mede—a great personality. Ardashir I (*q.v.*), son of Babek (Papag or Papak) and descendant of Sasan, was the sovereign of one of the small states into which Persis had gradually been divided. His father had taken possession of the city and district of Istakhr (Estakhr), which had replaced the old Persepolis, long a mass of ruins. Babek was succeeded by his eldest son, Shapur, who was soon killed in an accident, so that in A.D. 208 Ardashir came to the throne. He first built for himself an impregnable stronghold at Gor (Gur), also called after its founder Ardashir-Khurre, the modern Firuzabad in the recesses of Fars southeast of Shiraz. Then he subdued the neighbouring potentates, disposing also of his own remaining brothers. Ardashir's seizure of Carmania (Kerman), Isfahan, Elymais and Characene (Mesene) quickly led to war with his suzerain, Artabanus V. The conflict lasted for several years, and the Parthians were worsted in three battles. The last of these was the battle of Hormizdagan (224), which resulted in the death of Artabanus.

Yet though Ardashir appears subsequently to have occupied the capital, Ctesiphon, his progress to suzerain power could not have been without setbacks. Thus Vologaeses V struck coins at Seleucia as late as the Seleucid year 539 (A.D. 228/229). Another Parthian prince, Artavasdes, a son of Artabanus, is known also from coins on which his distinguishing feature is his forked beard. This personage retained a portion of the empire to an even later date.

TABLE II.—*Sasanian Dates Established on Direct Ancient Evidence*

Event	Regnal years	Seleucid era	Christian era
Accession of Artabanus (Ardavan) V	1		212/213
Inscription of Khwasak at Susa names Artabanus "king of kings"			215
Birth of Mani	5	527	216/217
Artabanus V overthrown and killed by Ardashir			224
Official first regnal year of Ardashir		538*	226/227
Last coin of Vologaeses V minted at Seleucia		539	228/229
Mani, in 13th year, receives divine revelation	3	539	228/229
Official first regnal year of Shapur I		553	241/242

*Syrian reckoning.

Moreover Ardashir on his coins is distinguished by no fewer than four different crowns: (1) as king of Fars; (2) before the battle of Hormizdagan as claimant to the empire; and (3) and (4) with two quite separate crowns as emperor. This situation suggests that Ardashir had more than one coronation ceremony as suzerain ruler, the second perhaps following on some short-term setback by which he temporarily lost the throne. A rock sculpture near Firuzabad depicts the overthrow of Artabanus by Ardashir. In another at Naksh-e Rostam near Persepolis, Ardashir tramples underfoot the vanquished Artavasdes. The members of the Arsacid line who fell into the hands of the victor were put to death. Yet a number of the princes found refuge in Armenia, where the Arsacid dynasty maintained itself until 428.

Ardashir then subdued Seistan (Sakastan), Gorgan (Hyrcania), Abarshahr (modern Khurasan), Merv (Margiana), Balkh (Bactria) and Khwarizm (Chorasmia). Since most of these territories had formed part of the Kushan empire, the implication is that he overcame the Kushans. This deduction is confirmed by the statement of al-Tabari that after these campaigns the kings of the Kushans, of Turan (Quzdar, south of Quetta) and of Makran made their submission to Ardashir. The victorious Ardashir also took possession of the palace at Ctesiphon, assuming the title "king of kings of the Iranians." The city of Seleucia he refounded after the fighting under the name of Veh Ardashir, "the good deed of Ardashir."

The chronology of events in the early Sasanian period was calculated by T. Nöldeke in 1879, and many authorities still adhere to his system of dating. The discovery, however, of evidence from later manuscript finds concerning the date of events in the life of Mani (*q.v.*), a religious leader active in the early Sasanian period, led W. B. Henning to call for a reassessment of this system of dating in favour of a revised system in which the chief events are dated about two years earlier. This view was disputed by S. H. Taqizadeh, who prefers another alternative in which the chief events are placed about six months later than the dates established by Nöldeke. Since the dating systems employed by the Sasanians themselves were based on the regnal years of the kings, whose exact coronation dates are often subject to dispute, a final solution of the problem is not yet possible. Errors in the various computations may have arisen from such circumstances as the possible second coronation of Ardashir, and the unknown lapse of time between the demise of one ruler and the coronation of his successor, a common source of discrepancy. Where the ancient authorities quote dates in terms of the Seleucid era—either according to the reckoning which prevailed in Babylonia, which commenced from 311 B.C., or the Syrian reckoning, counted from 312 B.C.—a firmer basis of calculation is obtained. In Tables II and III are set out dates established on the direct testimony of ancient coins or literary evidence, and the differing chronological systems of Nöldeke, Henning and Taqizadeh.

TABLE III.—*Chronological Systems of Nöldeke, Henning and Taqizadeh*

Event	Nöldeke	Henning	Taqizadeh
Ardashir's "first year" begins		Sept. 27, 223	Sept. 26, 226
Ardashir's actual accession	Sept. 26, 226	April 28, 224	April 6, 227
Shapur's first year begins		Sept. 23, 239	Sept. 22, 241
Shapur's actual accession	Sept. 22, 241		
Shapur's coronation		April 12, 240	April 9, 243
Shapur's death		May 270	April 273
Accession of Ormizd (Hormizd) I	Sept. 14, 272		
Ormizd's death		June 271	April 274
Accession of Bahram I	Sept. 14, 273		
Death of Mani (about age 60)		March 2, 274	Feb. 26, 277
Death of Bahram I		Sept. 274	July 277
Accession of Bahram II	Sept. 13, 276		

Source: T. Nöldeke, *Geschichte der Perser und Araber zur Zeit der Sasaniden* (E. J. Brill Ltd., Leiden, 1879); S. H. Taqizadeh and W. B. Henning, "The Dates of Mani's Life," *Asia Major*, vi, part 1, pp. 106–121 (London, 1957).

Wars of Shapur I.—Shortly before his death, no doubt as a consequence of failing health, Ardashir abdicated the throne in favour of his chosen heir, Shapur I. The latter, however, though assuming the responsibilities of government, delayed his coronation until after his father's death. Thus coins exist portraying Ardashir together with his son as heir apparent, and Shapur alone wearing the eagle cap as prince regnant before his coronation, besides the normal series of Shapur crowned as king. Immediately after his accession, Shapur was faced with an invasion of Persian territory by the Roman emperor Gordian III. He confronted the Roman forces at Massice on the Euphrates, defeating them in a major battle in which Gordian was killed. From this event the town of Massice received the name of Firuz-Shapur, though in

later history it is usually known as Al Anbar (*see* ANBAR). The survivors of the Roman force raised Philip the Arab to the purple, and he was able to negotiate a peace with the Persians, ransoming the Roman prisoners for a large sum of gold. In A.D. 256 (A.D. 252 according to other authorities) a dispute over Armenia led Shapur to invade the Roman provinces of Syria and Cappadocia, destroying a Roman army of 60,000 men at Barbalissus and capturing 37 cities, including the capital city of Syria, Antioch itself. When the emperor Valerian marched with a large force to the defense of Edessa, he was utterly routed by Shapur, who performed the unparalleled feat of personally taking prisoner the Roman emperor. The destruction of the Roman force laid Syria and Cappadocia open once more to devastation and plunder by the Persian armies, while the hapless Valerian was held prisoner in Persia for the remainder of his life.

Knowledge of the reign of Shapur I was greatly extended in 1938 through the discovery by the expeditions of the Oriental institute, Chicago, of a long inscription containing Shapur's own account of these events. This was found near Persepolis on the walls of an Achaemenian monument known as the Ka'aba-e Zardusht. The text is in three languages, Sasanian Pahlavi, Parthian and Greek, and, besides its narrative of the military operations, contains a description of the Persian empire of the time and an account of Zoroastrian religious foundations established by Shapur to commemorate his wars. These were fire temples dedicated to the memory of members of the Sasanian royal family and of the prominent officials who had served under Shapur and his predecessors; the officials are individually specified by name in a list which throws considerable light on the administrative arrangements of the kingdom at that time.

Organization of the Empire.—In contrast to his father, Shapur I assumed the title "king of kings of Iran and non-Iran" (*shahan shah Eran ut Aneran*), thus emphasizing his claim to world dominion. This formula was retained by his successors and became the regular designation of the Sasanian emperors. The supremacy of the ruler was powerfully emphasized under the dynasty of Ardashir. The hereditary local dynasties which under the Arsacids had ruled many of the most important provinces were to a large extent abolished. Instead, such fiefs as Maishan (Mesene) and Sakastan (Seistan) were ruled by members of the Sasanian family appointed by the sovereign with the title of shah (king). Among such viceroys precedence was often held by the heir to the throne, who was placed in control of great territories such as the conquered lands of the Kushan empire (Kushanshahr), or of Armenia, and entitled *vuzurg shah* ("great king"). Next in the hierarchy to royalty came a few remaining hereditary vassals, including the kings of Iberia (Georgia) in the Caucasus, and the chief nobles of the kingdom, of whom the Varaz, Suren and Karen retained their prominence from Parthian times. These were followed by the satraps, whose importance had considerably diminished since the Achaemenids and who were now no more than the administrators of substantial cities, and by the various officials of the court.

The extent of the Sasanian empire under Shapur I is defined by the list of provinces given in the inscription of the Ka'aba-e Zardusht. No fewer than 27 provinces are enumerated: (1) Persis; (2) Parthia; (3) Khuzistan; (4) Maishan; (5) Asuristan (*i.e.*, Iraq, the province of Ctesiphon); (6) Adiabene; (7) Arabistan (*i.e.*, northern Mesopotamia); (8) Azerbaijan; (9) Armenia; (10) Iberia; (11) Machelonia; (12) Albania; (13) Balasakan, extending to the Caucasus mountains and the Alans' Gates; (14) Patishkhwagar (*i.e.*, the Elburz mountains); (15) Media; (16) Hyrcania (*i.e.*, Gorgan); (17) Merv; (18) Aria; (19) Abarshahr; (20) Carmania; (21) Seistan; (22) Turan; (23) Makran; (24) Paratan; (25) India (the exact extent of the Sasanian province is undefined, but it may have been restricted to the Indus delta); (26) Kushanshahr, extending from before Peshawar to Tashkent, Sogdiana and the borders of Kashgaria; and (27) on the further side of the sea, Mazun (*i.e.*, Oman). This empire, considerably more extensive than that controlled by the Arsacid dynasty, was governed on behalf of the Sasanian dynasty not by feudal chiefs but by members of the dynasty and by appointed officials directly responsible to the throne. The greater degree of centralization attained by the Sasanian government no doubt partly explains its increased military effectiveness in comparison with the preceding administration of the Arsacids.

Another tendency which developed in the Sasanian period (and which indeed had already made itself felt under the Arsacids) was a strict principle of dynastic legitimacy. For a usurper not of the royal blood to achieve the throne was an extremely rare occurrence, though it was in fact accomplished by Bahram Chobin (*q.v.*). Allegiance attached, however, to the whole royal house, rather as it did in the later Ottoman empire. The person of the individual ruler was a matter of less importance, and one member of the dynasty could readily be removed and replaced by another. In accordance with this principle of legitimacy, Persian tradition carried the Sasanian line back to the Achaemenids and, still further, to the kings of the legendary period.

TABLE IV.—*Sasanian Kings**

Name	Reign years	Name	Reign years
Defeat of Artabanus (Ardavan)	224	Firuz	457 or 459–484
Ardashir I	226–241	Balash	484–488
Shapur I	241–272	Kavadh I (first reign)	488–496
Ormizd I	272–273	Jamasp	496–498 or 499
Bahram I	273–276	Kavadh I (second reign)	498 or 499–531
Bahram II	276–293	Khosrau I	531–579
Bahram III	293	Ormizd IV	579–590
Narses (Narseh)	293–302	Khosrau II Parvez (first reign)	590
Ormizd II	302–309	Bahram VI Chobin	590–591
Shapur II	309–379	Khosrau II Parvez (second reign)	591–628
Ardashir II	379–383	*Bistam* (rebel in Media)	591–596
Shapur III	383–388	Kavadh II Shiruya (Siroes)	628
Bahram IV	388–399	Ardashir III	628–630
Yazdegerd I	399–420	*Shahrvaraz*	630
Bahram V Gor	420–438	*Borandukht*	630–631
Yazdegerd II	438–457	*Ormizd V*	631–632
Ormizd III	457–459?	Yazdegerd III	632–651

*Based mainly on T. Nöldeke's chronology.

Religious Developments.—The forebears of Ardashir had played a leading role in the rites of the fire temple at Istakhr, known as Atur-Anahid, "The Anahit fire." With a dynasty having such priestly antecedents, it is natural to expect that important developments would have taken place in the Zoroastrian religion during the Sasanian period. Indeed the evolution of Zoroastrianism as an organized religion in something resembling its modern form can be regarded as having commenced in the period of this dynasty. Prior to the Sasanian period, there is little evidence of any centralized religious organization in Iran. Under the Parthians local Magi (*q.v.*) had no doubt continued to perform the traditional ceremonies associated with the old Iranian deities, the fire cult, the creed preached by Zoroaster, with its emphasis on the worship of Ahura Mazda, and even the cults of cosmopolitan deities introduced in the Hellenistic period and later.

It is probable that the Parthians enforced no sharp distinctions between these diverse forms of religious activity. Under the Sasanians, however, stress came to be increasingly placed on the fire cult and the worship of Ahura Mazda. Strong links were developed between religion and the state, and an ecclesiastical organization was evolved in which every considerable district had its mobed (*magupat*, "chief priest"). At the head of these stood the *mobedan mobed* (supreme priest), who in addition to his religious jurisdiction appears in later times to have exercised considerable influence in connection with the choice of a successor to the throne. There is some evidence that besides their religious function the Magi, by virtue of their proficiency in the complicated Pahlavi writing system necessary for the understanding of the Iranian scriptures, performed the offices of registrars and scribes, after the fashion of the Christian clergy in medieval Europe. The *magukhana* (Magus house) will thus have replaced the office of the Hellenistic bibliophylax (archivist) as the repository of the local archives, title deeds and other similar legal documents.

In the matter of religious practice, the rites of the Sasanians appear to have developed from those previously current in their home province of Persis. There extraneous religious influences were slight. The opposition between the good spirit of light and the demons of evil—between Ahura Mazda (*q.v.*; Ormazd) and

Ahriman—still remained the principal dogma of the creed. All the other gods and angels, however estimable their aid, were but subordinate servants of Ahura Mazda, whose highest manifestation on earth was less the sun-god Mithra than the holy fire guarded by his priests. At the same time the names of such deities as Verethragna (Bahram), Mithra and Anahit were still associated with the names of fire temples or classes of fire. All the prescriptions of purity—partly connected with national customs and impossible of execution abroad—were diligently observed. The elaborate ritual still maintained by the modern Parsees (*q.v.*) for the purification and custody of the sacred fire were no doubt observed under the Sasanians. The responsible priest was girt with his sword and carried in his hand the barsom, or bundle of sacred twigs. His mouth was covered to prevent the sacred flame sustaining pollution from his breath. Yet the practice of animal sacrifice, abhorred by the modern followers of Zoroaster, is attested in the history of the Sasanian period at least as late as the reign of Yazdegerd I (399–420). On the great festivals, such as the day of Nauruz (the Iranian new year) and the day of Mihrajan, the sacred fire was displayed to the faithful populace at nightfall from some point of vantage, a platform on rock or hill. Moreover under the Sasanians the injunction not to pollute the earth with corpses but to expose the dead on the mountain tops to vulture and dog was observed in its full force. At the same time Ahura Mazda preserved his character as a national god, who bestowed on his worshipers victory and world dominion. In the sculptures of the Sassanids, as also in Armenian traditions, he appears on horseback as a war god.

Under the Sasanians theology was further developed and an attempt made to modify the old dualism by envisaging both Ahura Mazda and Ahriman as emanations of an original principle of infinite time (Zurvan). This doctrine enjoyed a degree of official recognition under the earlier Sasanian reigns. Indeed the innovation had even been known earlier to the Mithra cult of the west, where Zurvan appears as Aion. However, in the reign of Khosrau I the "sect of the Zurvanites" was pronounced heretical. The chief development of Sasanian religion, apart from the process of institutionalization to which reference will be made later, was the elaboration of ritual and of the doctrine of purity. There was evolved a complete and detailed system of casuistry dealing with all things allowed and forbidden, the forms of pollution and the expiation of each, which recalls the similar prescriptions in the Pentateuch. The consequences of this development were that orthodoxy and literal obedience to priestly injunctions assumed an increasing importance. Heathenish cults and forbidden manners and customs came to be regarded as a pollution to the land and a deep insult to the true God. It became the duty of the believer to combat and destroy the unbeliever and the heretic. In short, the tolerance of the Achaemenids and the indifference of the Arsacids came to be replaced by increasing intolerance and religious persecution.

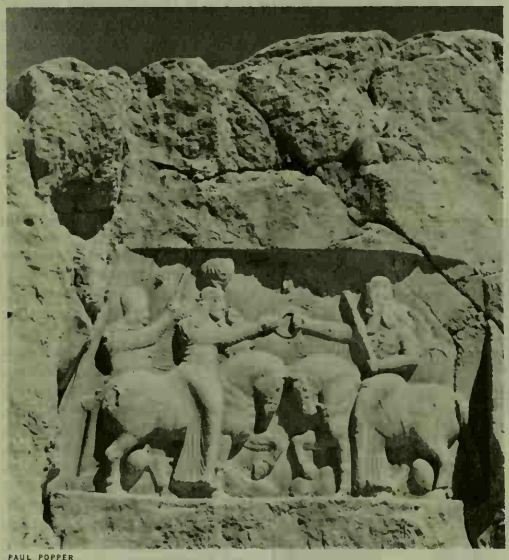
Such was the religious background to the inauguration of the Sasanian dynasty. Yet despite his priestly origins, Ardashir himself seems not to have been the person responsible for giving religious affairs this new direction. It was once believed that the institutionalization of the Zoroastrian church and the codification of its scriptures and beliefs was the work of a high priest named Tansar, contemporary of Ardashir I, of whose doings an account is preserved in the *Letter of Tansar* contained in the *History of Tabaristan* of Ibn Isfandiyar. The later interpretation of the Sasanian inscriptions of Fars, however, suggests that if Tansar was in fact a historical personage his role in these matters may have been less significant than that of Kartir, a Magus, or rather a *herbed*, prominent under Shapur I, who in the subsequent reign of Bahram II (A.D. 276–293, by Nöldeke's chronology) appears as the dominant figure in the Zoroastrian church. He claims credit for the suppression of non-Zoroastrian religious communities in Iran, for the imposition of orthodoxy and discipline in the Magus estate, and for the establishment of royal foundations making provision for the maintenance of Magi and of sacred fires.

The reference in the Pahlavi inscriptions of Kartir to two sects of Christians, besides Buddhists, Brahmans and other foreign religious communities, confirms the indications from Syriac sources that Christianity had by this time gained a firm footing in the countries of the Tigris and Euphrates, where it was naturally strongest among the Aramaic-speaking communities. Yet ultimately Christian missionary enterprise came to stretch over the whole of Iran and even farther afield. As long as the Roman empire remained pagan, the Christian communities of Iran lived undisturbed by persecution. At the same time the Christians themselves evidenced the strongest hostility toward the heterodox sects, such as the Manichaeans and the Gnostic followers of Marcion and Bardesanes, who existed side by side with them (*see* BARDESANES; GNOSTICISM; MANICHAEISM; MARCIONITES). However, when the emperor Constantine made Christianity the official religion of the Roman world, the Iranian Christians were, on the one hand, drawn to feel a certain sympathy for their foreign coreligionists, while, on the other, political significance came to be attached by the Sasanian rulers to these religious connections with an often hostile power. After A.D. 339, therefore, the Christians of Iran were subjected to severe persecutions at the hands of Shapur II and his

THE SASANIAN EMPIRE IN THE TIME OF SHAPUR I

successors. Nonetheless, substantial Christian communities survived in parts of Iran long after the close of the Sasanian dynasty.

At the same time, the old idea that every religion contained a portion of the truth and that it was possible to borrow something from one and amalgamate it with another had not lost all its power. From such a conception arose the teaching of Mani. Knowledge of Manichaeism was greatly increased by the discovery of many fragments of its literature in eastern Turkistan; these include portions of the *Shapuraghan*, a work in Middle Persian dedicated to the Sasanian emperor Shapur, and the *Evangel*. Subsequently a large part of the *Kephalaia*, a book of the religious injunctions of Mani, was recovered in a Coptic text from Egypt. These texts can be collated with the versions of Manichaean doctrines reported by the Church Fathers, among others St. Augustine. It is clearly seen that Manichaeism originated from a Gnostic sect. Mani was the offspring of a Parthian family resident in Babylonia but himself a speaker of Aramaic. He proclaimed himself as the last and greatest apostle of Jesus and as the paraclete announced in the Gospel of St. John. With the Gnostic interpretation of the Gospel he tried to combine the doctrines of Zoroaster and of Jesus to create a new universal religion. There is a tradition that he made his first appearance as a teacher on the coronation day of Shapur I, but other evidence suggests that Mani was not necessarily in Iran at that time but may have been occupied with his journey by sea to India when he commenced to preach. He subsequently returned and found many adherents, among whom are



PAUL POPPER

numbered Firuz (Peroz), a brother of Shapur, and Mihrshah, governor of Maishan, the province at the head of the Persian gulf. Even the king is said to have been impressed and to have granted the prophet no fewer than three interviews. The prophet's decision to dedicate to him the *Shapuraghan* is further evidence of a degree of royal favour. During the reign of Shapur the religion of Mani was thus propagated in Iran and beyond. Even the heir to the throne, Ormizd (Hormizd) I, was favourably disposed toward him; but Shapur's younger son, Bahram I, yielded to pressure from the priests, and Mani was executed. After that Manichaeism was persecuted and extirpated in Iran. Yet it maintained itself not merely in the west, penetrating far into the Roman empire, but also in the east, in Khurasan and beyond the bounds of the Sasanian dominion. There the seat of its pontiff was at Samarkand, whence Manichaeism penetrated into central Asia. There, buried in the desert sands which entomb the cities of eastern Turkistan, have been discovered numerous fragments of the works of Mani and his disciples. They are written in a form of the Syrian script adapted by the Manichaeans for their scriptures, and in the Middle Persian and Parthian languages; others are in the east Iranian Sogdian dialect.

Art and Literature.—Perhaps the most characteristic and certainly among the most striking relics of Sasanian art are the great rock sculptures carved on the abrupt limestone cliffs which are found in many parts of the country. The best-known groups are at Naksh-e Rostam and Naksh-e Rajab, near Persepolis, and at Shahpur (Bishapur), the ancient city a few miles north of Kazerun in Fars. At Firuzabad, the ancient Gor, in the same province, are two reliefs of Ardashir, one depicting his overthrow of Artabanus V, the other an investiture scene. Not far away in the lonely valley at Sar Mashad, a representation of Bahram II slaying two lions was discovered by E. Herzfeld in 1932. At Darabgird a ruler of uncertain identity, perhaps Ardashir, is shown triumphing over a Roman emperor, while at Naksh-e Bahram, north of Kazerun, Bahram II is depicted enthroned; the same ruler appears in small reliefs at Qasr-e Abu Nasr, near Shiraz, and at Guyom, not far away. Sasanian sculptures are less numerous outside the province of Fars, where such work may have been put in hand by the Magus Kartir, but an equestrian figure which once existed at Ray was replaced in the 19th century by a representation of the Qajar king Fath Ali Shah. At Shahpur (formerly Salmas) on Lake Urmia (Reza'iyeh) Ardashir is shown on horseback receiving the surrender of Parthian personages. There are later Sasanian sculptures at Taq-e Bostan, near Kermanshah, showing Ardashir II, Shapur III and Khosrau II. In many of these sculptures the Sasanian kings can be recognized by their individual crowns, but a poorly preserved relief at Finik, near Jazirat Ibn Umar in Iraq, reported by Sir A. H. Layard and G. Bell, may be of pre-Sasanian date. At Sar-e Pul in Afghanistan a rock carving seen by J. P. Ferrier before 1856 has never been relocated. It may, however, be Sasanian.

The most celebrated architectural achievement of the dynasty is no doubt the vast palace at Ctesiphon (*q.v.*), built by Khosrau II, of which a part is still standing. It is known as the Taq-e Kisra, and is notable for its great barrel vault in baked brick, a typically Sasanian device. Many Sasanian buildings can also be seen in Fars, where the characteristic construction is of limestone blocks embedded in strong mortar. The most important of these is the palace of Ardashir at Firuzabad (*q.v.*), and a small, well-preserved palace at Sarvestan, in which the rooms are roofed with domes and squinches, features often found under the Sasanians. French excavations at Shahpur near Kazerun have revealed some mosaic floors, among other features of the considerable Sasanian town. Numerous fire temples of the period survive, especially in Fars; these are square buildings roofed by a dome over four arches. Moreover Sasanian remains of considerable extent exist at Qasr-e Shirin, on the Baghdad-Teheran road, and at Jundai Shapur (modern Shahabad, south of Dezful).

The Sasanian epoch was indeed one of a general renascence in Iranian art, which if not on the same level as the Achaemenian achievement was of no small importance. Metalwork of the period enjoyed a high reputation, its most characteristic decorative theme being hunting scenes portraying the Sasanian kings. The position of Iran on the silk route between China and the west encouraged the establishment of an important silk industry, which often supplied the Roman world and of which the influence can be traced in the west. The art of gem engraving produced many intaglio stamp seals, especially of the characteristic domed shape, and a few fine cameos. The coins invariably bear a Pahlavi legend—on the obverse the head of the king, wearing his characteristic crown, and accompanied by his name and title; on the reverse the fire altar with its guardians and the inscription "fire of Ardashir, Shapur, etc." or, in the later period, an abbreviated mint name and the regnal date.

The acquaintance with the Greek language and literature maintained by the Arsacid court was already in decline during the last

century of that dynasty. Nonetheless Greek translations accompany the inscriptions of Ardashir I and Shapur I, notably the long Greek version of the latter's great inscription at the Ka'aba-e Zardusht, which may show traces of Parthian official terminology. Later inscriptions, however, are only in Parthian and Pahlavi (in the cases of the inscription of Narses at Paikuli) or in Pahlavi alone. Little of the surviving literature in book Pahlavi is as old as the Sasanian period. A few works, however, contain material which goes back to the period of Khosrau I (531–579). The *Dadhastan i Menoghkhrad* ("Doctrine of Celestial Wisdom") and the *Ardagh Viraz-Namagh* ("Vision of Ardagh Viraz") contain material on Zoroastrian theology. The *Madhighan i Hazar Dadhastan* ("Account of a Thousand Decisions") is a compendium of Sasanian law, which names many Sasanian jurists and quotes their opinions. The *Karnamak-i Ardashir-i Papakan* contains a version of the life of Ardashir I which, though legendary, is shown by Agathias to have been current in the late Sasanian period. The *Letter of Tansar*, mentioned above, though perhaps also legendary, is taken from a Pahlavi work of the time of Khosrau. The later compilations, especially the *Denkard*, though mainly concerned with cosmology and religious legend, contain some important historical references relating to the Sasanian period. According to one of these, Shapur I ordered the collection and translation of religious, astronomical, medical and philosophical texts from the Byzantine empire and from India. Other translations from Indian literature are known under the Sasanians; *e.g.*, the book of tales called *Kalilah and Dimna*, the legends of Barlaam and Josaphat and the Indian legends in the *Letter of Tansar*. The books of moral precepts (*andarz*) constitute another important genre in Sasanian literature, which, with the orally transmitted popular romances in verse, are often reflected in the writings of the Islamic period.

Foreign Policy.—In foreign policy the problems under the Sasanian kings remained, as of old, the defense and, when possible, the expansion of the eastern and western frontiers. In the east Ardashir I had quickly defeated the Kushans, annexing the western part of their empire. There are indications that Shapur I before his accession had played a leading part in these operations, and was probably the first Sasanian prince to bear the afterward well-established title of *Kushanshah*, "Viceroy of the Kushans." His inscription defines the Kushan province under Sasanian rule as extending from the Indus to Sogdiana and the boundaries of Kashgar. Successors of the Kushans seem to have retained some independence only in the Punjab, where they were still subject to Sasanian inroads until they finally succumbed to the expanding Gupta empire of India in the mid-4th century. Farther south, the Sasanian governorate of Sakastan included "India [? Sind] and Turan (Quzdar) to the shores of the Indian ocean." Thus all the local principalities of Baluchistan had come under Sasanian control.

In the west, the old contest for Osroene and northern Mesopotamia with the fortresses of Carrhae, Nisibis (Nusaybin) and Edessa still smoldered. The Sassanids were all the more eager to regain Armenia because there the Arsacid dynasty still survived and turned for protection to Rome, with which, in consequence, new wars perpetually broke out. In the reign of Bahram II the emperor Carus, burning to avenge the disaster of Valerian, invaded Mesopotamia without meeting opposition and reduced Coche (near Seleucia) and Ctesiphon; but his mysterious death in Dec. 283 prevented further success, and the Roman army returned home. Bahram had been diverted from the scene by the dangerous rebellion of his brother, the Kushanshah Ormizd (Ormies), who had occupied Merv and Herat, claiming imperial status for his Kushan viceroyalty. He was however defeated by Bahram, who was able to appoint his younger son, the future Bahram III, as viceroy of Sakastan. After the father's death, Narses, the youngest son of Shapur I, then viceroy of Armenia, contested the succession of Bahram III and won the crown. In memory of his victory he erected a great tower at Paikuli, in the mountains west of the upper Diyala, discovered in 1843 by Sir Henry Rawlinson and investigated in three expeditions by E. Herzfeld. Decorated with busts of Narses, the monument bears a long inscription in Parthian and in Sasanian Pahlavi, recounting the history of these events. After his victory Narses occupied the independent portion of Armenia. In the following year he sustained a severe reverse in that province, losing his war chest and his harem. He then concluded a peace, by the terms of which Armenia remained under Roman suzerainty, and the steppes of northern Mesopotamia, with Singara and the hill country on the left bank of the Tigris as far as Gordyene, were ceded to the victors. In return Narses recovered his household. By this peace, concluded in 296, which lasted for 40 years, the Sasanians withdrew completely from the disputed districts.

After the death of Ormizd II, the son of Narses, the nobles imprisoned or put to death his adult sons, one of whom, Ormizdas (Hormisdas), later escaped to the Romans, who used him as a pretender in their wars. Shapur II (*q.v.*; 309–379), a posthumous child of the former king, was raised to the throne, proof that the great nobles held the sovereignty in their own hands and attempted to order matters at their own pleasure. Shapur, however, when he came to manhood proved himself an independent and energetic ruler.

Renewed Conflict With Rome.—Meanwhile, the Roman empire had become Christian, so that the Syro-Christian populations of Mesopotamia and Babylonia began to feel some sympathy with Roman policies. For similar reasons Christianity became predominant in Armenia; as early as 294 King Tiridates was converted by St. Gregory the Illuminator and adopted the Christian faith. The Sasanian empire was thus the more constrained to consolidate its Zoroastrianism. Under Shapur II the compilation of the Avesta was completed, and state orthodoxy perfected by the chief mobed, Adhurbad. All heresy was proscribed by the state, defection from the true faith was pronounced a capital crime and the persecution of the heterodox—particularly the Christians—began. Thus the duel between the two great empires became simultaneously a duel between two religions.

In this situation a fresh war with Rome was inevitable. It was begun by Shapur in 337, the year that saw the death of Constantine the Great. The conflict focused upon the Mesopotamian fortresses, Shapur thrice besieging Nisibis without success. The emperor Constantius conducted the war feebly, but Shapur was diverted by the appearance of a new enemy, the nomadic Chionites (Huns; *see* HEPHTHALITES), on his eastern frontier. He campaigned against them for five years (353–358) in Khurasan, giving its modern name to the great city of Nev-Shapur (Nishapur; *q.v.*), formerly known as Abarshahr. Finally, winning over the Chionites as his auxiliaries, he returned to Mesopotamia and stormed Amida (359), an episode vividly narrated by Ammianus Marcellinus; the next year he also reduced Singara.

Julian the Apostate (363) undertook an invasion of the Persian empire, also described in detail by Ammianus. He pressed forward to the neighbourhood of Ctesiphon but succumbed to a wound. His successor, Jovian, found himself in such straits that he could extricate himself and his army only by a disgraceful peace at the close of 363; this ceded the possessions on the Tigris and the great fortress of Nisibis, and pledged Rome to abandon Armenia and its Arsacid protégé, Arsaces III, to the Persians. After desperate Armenian resistance, the greater part of the kingdom was made a Persian province under a *marzpan*.

From Yazdegerd I to the Turks.—After several disturbed reigns Yazdegerd I (*q.v.*; 399–420) came to the throne. His reign is differently viewed by Christian and Magian sources. The Christian writers praise his clemency, but the sources dependent on the Magian tradition refer to him as "Yazdegerd the Sinner." Inclined to tolerance of the Christian and Jewish religions, Yazdegerd was concerned to limit the power of the nobles, whose obdurate resistance finally drove him to severity. Furthermore, the growing fanaticism of the Christians made repression at last unavoidable. In the end Yazdegerd was probably assassinated. The nobles refused to admit any of his sons to the throne, but one of them, Bahram V, was supported by al-Mundhir, Arab prince of Hira, and also apparently by Mihr-Narseh, chief minister of Yazdegerd's last years, whom Bahram retained in office subsequently. As king Bahram (*q.v.*), surnamed Gor, "the Wild Ass," became the favourite of Persian popular tradition, which is eloquent on his

adventures in the chase and in love. Unsuccessful in a war with Rome (421–422), Bahram made a peace granting freedom of worship to the Christians. On his eastern frontier he was successful in repelling an invasion by a new wave of nomadic Hephthalites. However, in the succeeding reigns continued Hephthalite attacks harassed and weakened the Sasanians. Firuz (*q.v.;* 457 or 459–484) fell in battle against them; his treasures and family were captured and the country devastated. His brother Balash (484–488), unable to repel them, was deposed and blinded, the crown being bestowed on Kavadh I (*q.v.;* 488–531), son of Firuz. As the empire continued to suffer distress, he was dethroned and imprisoned; but he escaped to the Hephthalites and was restored in 498 or 499 by their assistance. The Nestorian doctrine had now become dominant among the Christians of Iran. Already favoured by Firuz, in 483 it was adopted by a synod and definitively established as the regular form of Christianity in the Sasanian empire.

Kavadh proved himself a vigorous ruler. He restored order in the interior and in 502 attacked the Romans and destroyed Amida (modern Diyarbakir), but was compelled to ratify a peace because of an inroad of the Huns. Toward the close of his reign (527) he resumed the war, defeating Belisarius at Callinicum (531), with the zealous support of the Arab al-Mundhir II of Hira. Early in his reign he had inclined away from the Zoroastrian church and favoured Mazdak, the founder of a communist sect which had made headway among the people (*see* MAZDAKISM). The crown prince, Khosrau, however, was an orthodox Zoroastrian; toward the close of his father's reign, in conjunction with the chief mobed, he contrived the condemnation of the Mazdakites, who were butchered in a great massacre (528). On his father's death, acceding as Khosrau I (*q.v.;* 531–579), surnamed Anushirvan ("of the immortal spirit"), he concluded peace with Justinian (532). He re-established Zoroastrian orthodoxy, yet though some persecution of the Christian communities occurred during periods of hostilities against Byzantium, the restoration of peace saw a return of tolerance.

Khosrau I was one of the most illustrious sovereigns of the Sasanian empire. From his time dates a new and equitable adjustment of the imperial taxation. The levying of land revenue in kind was replaced by a fixed assessment in cash, and these assessments continued in force later under the Arabs. His reputation as an enlightened ruler stood so high that when Justinian in 529 closed the philosophy school at Athens, the last Neoplatonists bent their steps to him in hopes of finding in him the true philosopher-king. Though disillusioned with conditions at the court, their gratitude was great when Khosrau by the peace of 549 obtained for them the right to return. From 540 onward he had been conducting a great war against Justinian, which, interrupted by several armistices, lasted until the 50 years' peace of 561. The net result, indeed, was merely to restore the status quo; but during the campaign Khosrau sacked Antioch and transplanted the population to a new suburb of Ctesiphon (540). He also extended his power to the Black sea and the Caucasus. On the other hand, a siege of Edessa failed (544).

The Turks.—Meanwhile, about 560, a new nation, that of the Turks, had appeared in the east. By concluding an alliance with them Khosrau crushed the Hephthalites and conquered Bactria south of the Oxus. Inevitably this alliance soon turned to hostility, and in the second Roman war the Turkish khan was leagued with Rome.

Khosrau bequeathed this war to his son Ormizd IV (579–590), who in spite of repeated negotiations failed to re-establish peace. Ormizd had not the ability to keep his father's authority, and he further affronted the Magian priesthood by declining to take action against the Christians. Eventually he succumbed to a conspiracy of his nobles headed by the general Bahram Chobin (*q.v.*), who had defeated the Turks and was afterward beaten by the Romans. Ormizd's son, Khosrau II, was set up against his father and forced to acquiesce in Ormizd's execution. But immediately new risings broke out, in which Bahram Chobin—though not of the royal line—attempted to secure the crown, while simultaneously a Prince Bistam entered the lists. Khosrau fled to the Romans and the emperor Maurice undertook his restoration at the head of a great army. People flocked to his standard; Bahram Chobin was routed (591) and fled to the Turks, who slew him, and Khosrau again ascended the throne at Ctesiphon. In Media Bistam held out until 596.

Khosrau II (590–628), though distinguished by the surname Parvez ("the Victorious"), lived to witness unparalleled vicissitudes of fortune. He achieved a splendour and material wealth unprecedented in a lavish period. The assassination of Maurice in 602 impelled him to a war of revenge against Rome, in the course of which his armies penetrated as far as Chalcedon opposite Constantinople, ravaged Syria, reduced Antioch (611), Damascus (613) and Jerusalem (614), and carried off the true cross to Ctesiphon; in 619 Egypt was occupied. Meanwhile the Roman empire was at its lowest ebb.

The great emperor Heraclius, who assumed the crown in 610, took years to create the nucleus of a new military power. This done, however, he took the field in 622, and retaliated vigorously against the Persians. Their armies were everywhere defeated. In 624 he penetrated into Atropatene (Azerbaijan) and destroyed the great fire temple; in 627 he entered the Tigris provinces. Khosrau attempted no resistance, but fled from his residence at Dastagerd to Ctesiphon. A revolution followed in which Khosrau was deposed and slain by his son Kavadh II (628). When Kavadh died a few months later anarchy resulted. The true cross was meanwhile returned to Heraclius. After a succession of ephemeral rulers, the nobles united, and in 632 elevated to the throne Yazdegerd III (*q.v.*), grandson of Khosrau.

The Arabs.—Prolonged hostilities had drastically enfeebled both the great powers. Room was given to a new enemy that now arose against both states and religions—the Arabs. After several encounters the fate of the Sasanian empire was decided at the battle of Kadisiya (637) on one of the Euphrates canals. Ctesiphon with all its treasures was laid at the mercy of the victors. The king fled to Media, where his generals attempted to organize resistance; but the battle of Nahawand (641) decided matters there. Yazdegerd sought refuge in one province after another, until at last, in 651, he was assassinated near Merv (*see* CALIPHATE).

The fall of the empire sealed the fate of its religion. The Muslims officially tolerated the Zoroastrian faith, though persecutions were not unknown. But little by little it vanished from Iran, except for the few survivors who remain at Yazd. Other Zoroastrians found refuge in western India, where they are now chiefly concentrated at Bombay. These Parsees (*q.v.*) have preserved but a small part of their sacred writings; but they still number their years by the era of Yazdegerd III, the last king of their faith and the last Sasanian sovereign of Iran. (A. D. H. B.)

VI. FROM THE FALL OF THE SASSANIDS TO THE RISE OF THE SAFAVIDS, 651–1501

Arab Caliphates.—After the Arab conquest the greater part of Iran was divided into four provinces: Khuzistan and Fars, attached to Basra; Media or Iranian Iraq, attached to Kufa; Khurasan; and Seistan. Arab tribal forces were established in a number of garrison towns (such as Qom and Shiraz), the largest bodies of them being settled in Khurasan (Nishapur, Merv, Herat, and later on Balkh, Bukhara and Samarkand), to serve as effectives for further conquests in central Asia. The Arabs interfered little with the Iranian population or their religions. For the most part the feudal nobility (*dihkans*) and the small principalities in the east were left in possession of their lands and privileges, subject to good behaviour and the payment of a stipulated rate of taxation or tribute, for which the local *dihkans* acted as collectors. Relations between the Arab administration and the feudal classes seem to have been generally good, and a contingent of Iranian troops assisted the Arabs in the conquests in Transoxiana (notably under Kutaiba ibn Muslim, 705–715) and in repelling the later counterattacks of the central Asian Turks. There is evidence that the Arabs intermarried extensively with the Iranian population and that at an early date the mingling of the two speeches had begun to lay the foundations of the modern Persian language.

On the other hand, increasing fiscal pressure under the later Omayyads caused discontent among the cultivators and townsmen, as well as among a number of *dihkans*. The social strains result-

ing from the old feudal system also were intensified as large numbers of Iranians were converted to Islam, with its equalitarian ideals. These discontents were exploited by the missionaries of Arab revolutionary groups opposed to the Omayyad caliphate, and particularly, from 745, by an emissary of the Abbasid family named Abu Muslim (*see* CALIPHATE). By clever tactics he took advantage of the tribal feuds by which the Arabs in Khurasan were divided; and, adding his weight to a general rising of the Yemenite (or southern Arab) faction, he drove the Omayyad governor, Nasr ibn Sayyar, out of Khurasan and, on the occupation of Iraq by the Khurasanian forces, succeeded in supplanting the Omayyads by the Abbasid caliphate (750).

The Abbasid caliphs based their military power upon a standing army of Khurasanians, both Arabs and Iranians, stationed at Baghdad, and their administration, under the influence of Khurasanian nobles, notably the Barmecides (*q.v.*), was closely assimilated to the former Sasanian regime. When, however, the second Abbasid caliph, al-Mansur, suspicious of Abu Muslim's power and designs in Iran, murdered him in 754, a series of insurrections by his followers disturbed the peace in Khurasan for about 50 years. After the overthrow of the Barmecides a serious general rising broke out and Harun al-Rashid died at Tus on the way to suppress it (809).

The government of Khurasan passed to Harun's son al-Ma'mun, who restored order but quarreled with his brother, the caliph al-Amin. A new Khurasanian army was raised, commanded by the Iranian general Tahir ibn Husain, who besieged and captured Baghdad and killed al-Amin (813). After much fighting the Khurasanians re-established the caliph's control over the Arab provinces, but when a fresh insurrection threatened to break out in Iran under Mazdakite leadership al-Ma'mun found it necessary to appoint Tahir viceroy of Khurasan and the east (821). Tahir was succeeded by his sons, and until 872 the Tahirids constituted a practically independent dynasty and at the same time held the command of the caliphs' Khurasanian guard at Baghdad. During the half-century of Tahirid government a great part of northeastern Iran probably enjoyed a measure of security and prosperity greater than it had known for several centuries. Tahirid power, however, was really effective only in the region of Khurasan centred on their capital at Nishapur. But their influence extended farther because members of the family held posts at Baghdad and Samarra, which meant Tahirid influence on areas governed either directly from the metropolis or by its nominees. Conditions in Khurasan by about 870 and the capture of Nishapur by Yaqub ibn al-Layth indicate that prosperity did not long survive the decline of Tahirid power.

Minor Dynasties.—The Tahirids, though semiautonomous in Khurasan, represented a continuation in altered terms of the Arabs' compromise with the Iranian landowning aristocracy. The caliphate's increasing weakness; its distraction on account of the Zanj rebellion (869–883), which engaged al-Muwaffak, who might otherwise have restored Abbasid power; and the disappointment of the Iranian masses, who had rallied to Abu Muslim and helped to raise the Abbasids, in the Abbasid family—all were factors which encouraged movements claiming greater independence. The Abbasid-Tahirid regime in Iran could only with difficulty suppress the religio-political rebellion of the *khurramis* in Azerbaijan and made no headway against Iranian chiefs and Shi'ite refugee leaders on the Caspian littoral and in the adjacent mountains. From 865 more far-reaching movements than these local insurrections arose. These were helped by the prevailing insecurity consequent upon Kharijite activities. This sect carried to extremes the democratic ideas latent in Islam and practised excessive puritanism. To them neither the Omayyads nor the Abbasids were acceptable, while to another faction, the Shi'a, only descendants from the Prophet through his son-in-law, Ali, had the right to lead the Muslim community. Iran became the scene of Kharijite depredations and Shi'ite intrigues. The latter flourished for a time when al-Ma'mun attempted reconciliation with Shi'ite leaders, and, in the meantime, a Shi'ite dynasty had become established in the Caspian region, with influence in neighbouring Dailam. Kharijite outrages favoured the rise in Seistan of the Saffarid dynasty (*see* SAFFARIDS), whose founder, Yaqub ibn al-Layth, posed as a suppressor of their disorders while recruiting Kharijite warriors into his army. He was thus soon strong enough to control the whole of eastern Iran from Balkh to Shiraz, and from bases in Khuzistan eventually threatened the caliphate itself. He liquidated Tahirid power in Khurasan. Although his achievements have left Iranians the memory of a great hero, ousting the Tahirids from the north left a power vacuum in Khurasan to be filled by forces that had coalesced under another Iranian, Ismail the Samanid, who defeated Yaqub's brother Amr in 900.

The Saffarid ("coppersmith") dynasty's origins had been popular. The Samanids (*q.v.*) were aristocrats, but they also expressed Iranian reaction against Arab domination. Their main cities, Samarkand and Bukhara, enriched by extensive commerce with the far east, became centres of learning and the arts. Persian emerged as the language of great poetry; philosophy and history were encouraged and the foundations of Iranian Islamic culture laid. The Samanids were unable to conquer the Shi'ite leaders in the mountains of Dailam, whence issued the Buyids (*q.v.*). The three sons of Buya, a former Samanid officer, succeeded in gaining control of the caliphate and, as the Samanids did in the northeast, established an Iranian interlude in western Iran and Iraq. Both powers, their vassals and those who ruled where their power was not effective, were supplanted in the 11th century by the Seljuks. Arab power had either been infiltrated or repulsed altogether, but the way had been opened to another race of nomad tribes, this time from central Asia.

Ghaznavid and Seljuk Turks.—After the middle of the 9th century, the practice grew up in all Muslim kingdoms of purchasing Turkish prisoners and slaves from central Asia and forming them into regiments of guards (*see* MAMELUKE). As each dynasty weakened, its Turkish officers acquired an increasing measure of control and occupied the chief political offices at the capital and in the provinces. This led in due course to armed rivalries and revolts, by which the power and authority of the dynasty were undermined. The Samanids, after their conquest of Afghanistan, had established a Turkish officer as governor in Ghazni; this officer's son, Alptigin, ousted by a rival from his command in Khurasan, withdrew to Ghazni in 962 and defied the Samanid prince. He was succeeded by his son and several of his Mamelukes, the third of whom, Subuktigin (976–997), made his peace with the Samanids and obtained the government of Khurasan in addition to Ghazni. Subuktigin was succeeded after a year's interval by his son Mahmud (*see* MAHMUD OF GHAZNI), the first of the great military sultans, under whom the Muslim invasion of India began. When the Turkish Il-khans destroyed the Samanid kingdom, Mahmud kept them out of Khurasan and finally forced them to acknowledge his suzerainty. His government was a centralized military despotism in which the old feudal structure was gradually broken down; his administrative officers, however, were drawn from the landowning classes in Khurasan, where the old traditions of the Tahirids were still preserved; and their strong Sunni sympathies contributed to Mahmud's championship of the Abbasid caliphs against the Buyids and other Shi'ite sectaries.

At the end of the 10th century the converted Turkish tribes of central Asia, under the leadership of the Il-khans, had occupied Transoxiana. Among the nomadic Turkmen groups that had migrated into the country, one, the Ghuzz, was transported by Mahmud to Khurasan. During a struggle between Mahmud's sons, the Ghuzz, led by Togrul (*q.v.*) and Chakir of the Seljuk family, allied themselves with the nobles of Khurasan, defeated the Ghaznavid army at Dendenkan (1040) and set out on the conquest of western Iran (*see* SELJUKS). Togrul entered Baghdad in 1055, and he and his successors Alp Arslan and Malik Shah (*qq.v.*), aided by the great Khurasanian vizier Nizam al-Mulk, united the whole of Iran, with Iraq and Syria, under their rule. Each province was assigned to a Seljuk prince (*malik*), whose army was maintained by military fiefs (*ikta*). After Malik Shah's death the rivalries of these princes led to renewed disintegration, except in Khurasan where his son Sanjar maintained order until 1153. Most of the other principalities were taken over piecemeal by former officers of the Seljuk army, called atabegs, who founded new dynasties, the

most important of which in Iran were the atabegs of Azerbaijan and the Salghur Turkmens of Fars. Favoured by this disintegration, the Shi'ite sect of the Assassins (*q.v.*) firmly established themselves in the highlands of Dailam and by their terrorism contributed to the demoralization of the governing classes.

The massive immigration of Turkmen tribes accompanying the Seljuks also made heavy inroads on the economy of Iran. Much cultivated land was turned into pasture, and only the walled cities and fortresses provided a measure of security for their environs, from which the revenues of the military fiefs were drawn. The devastation was increased when fresh bands of Ghuzz swarmed into Khurasan, defeated and captured Sanjar and looted its cities before moving on to occupy Kerman and to extinguish the Seljuk principality there. Sanjar's territories were disputed between his former vassals, the shahs of Khwarizm (Khiva), and the chiefs of Ghor in Afghanistan; eventually the Khwarizm-shah Takash (1172–99) conquered Khurasan and Isfahan, and his son Ala ud-Din Mohammed (1199–1220) drove out the Ghorids, conquered the rest of Iran and occupied Transoxiana. Their armies, recruited mainly from the half-pagan Kipchaks of the steppes, added to the general rapine and disorder, and the Khwarizm-shah himself devastated the border lands of Transoxiana in his conflicts with the Turkish khans in central Asia.

Mongols.—It is thus historically false to represent the Mongol invasions as suddenly and ruthlessly tearing down a flourishing civilization and prosperous economy and reducing Iran to a desert. Their effect was rather to intensify the process of nomadization, by destroying most of the cities—especially those of Khurasan during the first invasion under Genghis Khan in 1220—and disrupting the organizations in which the old traditions of Persian-Islamic culture were still cultivated. It was as if, in medieval Europe, the cities and schools of Italy and France had been laid in ruins and their populations killed or dispersed. Except for a few individuals in the service of the Mongols, learning and culture survived only in the peripheral regions, of which Fars was the most important. There is therefore some symbolic truth in the popular view of the Mongols, insofar as they finally destroyed the social and economic foundations upon which the culture of Persia had rested, even if more and more precariously, for a thousand years.

Under the successors of Genghis Khan the Mongols extended their power over the whole of Iran and consolidated it by a fresh invasion led by his grandson Hulagu (*q.v.*), who destroyed the Assassin fortresses in 1256 and captured Baghdad in 1258, putting the last of the Abbasid caliphs to death. Hulagu thus became the first of the new "provincial dynasty" (Il-khans; *q.v.*) of Iran, which, though nominally subordinate to the Mongol Great Khan in China, governed their territories as autonomous princes until 1335.

The Il-khans.—Except for occasional conflicts with their Mongol kinsmen of the Golden Horde to the north and the Jagatai khanate to the east, the external policy of the Il-khans was directed for about 50 years toward the conquest of Syria. This brought them into conflict with the Mamelukes of Egypt (*see* EGYPT: *History*) and some ineffectual negotiations with the crusaders and the Christian powers, but their ephemeral seizures of Aleppo and Damascus in 1260 and 1303 were terminated by crushing defeats.

In internal affairs the most constructive policy of the Il-khans was their interest in trade, which was directed through Azerbaijan to the Black sea and made Tabriz a centre of international commerce. They introduced a new system of administration and taxation which continued into the Safavid period but was constantly impeded by tribal risings and military disturbances. Religious questions also created many difficulties. The early Mongols were Buddhists, but were generally tolerant toward Islam and all other religious communities. The third Il-khan, Ahmed Takudar, adopted Islam in 1282 but was dethroned by the Mongol nobles and replaced by his nephew Arghun, under whom there was a reaction against the Muslims. His employment of a Jewish doctor, Sa'd al-Dawla, as finance minister in 1288, and the latter's severe measures against the Muslims, led to such general disorder and discontent that Sa'd al-Dawla's downfall and execution was followed by violent pogroms in all the provinces. A still more disastrous attempt was made in 1294 to issue paper currency, in imitation of the Chinese *chau*, but without monetary backing. In the following year Arghun's son Ghazan was raised to the throne, although he was already converted to Islam, and set on foot an impressive series of measures of reform. Most of them aimed at reconstituting the pre-Mongol land system, including military fiefs, and restoring order and security, but Ghazan's early death (1304) prevented him from carrying them through.

Although the economic results of Ghazan's reign were quickly dissipated, the political and religious results were important. Islam again became the official religion of the state, and its religious and social institutions benefited from state support. Most of the Mongol nobles and tribesmen in Iran had by now been converted to Islam, and the faith was making rapid progress also in the neighbouring khanate in central Asia. The reign of Ghazan's brother Ulja'itu (1304–16) was a period of relative tranquillity and moderate prosperity. Under his nephew Abu Said (1316–35) the internal and external forces of disruption became too strong to hold down. Powerful officers contended for control of the Il-khanate, and after his death set up rival successions of puppet princes. The contest was won finally by the Mongol Jelairs, whose chief, Hasan Buzurg (1336–56), established them in power in Iraq and Azerbaijan.

Out of the confusion which attended the decay of the Il-khans, Fars and Herat (in both of which local dynasties had continued under Mongol rule for several decades) regained independence—Herat under its former Ghorid princes, known as the Kurts, Fars under the dynasty of Muzaffar. Besides the Jelairs, other nomadic chiefs governed parts of Iran, notably in Luristan. A more remarkable phenomenon was the success of an association of local bands in Khurasan who called themselves Serbadars and controlled most of the province, an instance of the new kind of associations which were growing up (mostly in relation to some Sufi leader or group) among the general population, in reaction to the political anarchy of the preceding centuries. The most notable political event of the period was the failure of an attempt by the Golden Horde to seize Azerbaijan (1357), while the economic decay of Iran was accentuated both by the disruption of trade routes and by disastrous plagues.

Whatever elements of urban culture survived these disasters were almost entirely destroyed by Timur (*q.v.*). The Mongol Il-khans had only with much difficulty protected the eastern frontier against the Jagatai khans of Transoxiana. This task, on passing to the Kurt kings of Herat, was eased for a time by internal dissensions in the Jagatai khanate. But when, between 1370 and 1380, Timur recreated a centralized power at Samarkand, they were powerless to resist, and after the fall of Herat in 1383 he swept over Iran without meeting effective opposition. Later risings were put down with ruthless cruelty; city after city was destroyed and their populations were massacred, except for the craftsmen who were transported to Samarkand to embellish the conqueror's capital. (H. A. R. G.; P. W. A.)

Timurids and Turkmens.—Timur died as he was setting out on an expedition to China (1405), and his conquests were divided between numerous descendants, of whom his sons Miranshah (d. 1407) and Shahrukh held western and eastern Iran respectively, and a grandson, Pir Mohammed, held Fars. The devastation and depopulation of Iran had left only three centres of power outside Transoxiana; these were Herat, Fars and Tabriz, and the conflicts of the next century developed into a struggle between Herat and Tabriz. Rivalries and warfare among the Timurids weakened them against the Turkmens of Azerbaijan and Armenia, themselves grouped in two rival confederacies, the Kara-Koyunlu (Black Sheep) and Ak-Koyunlu (White Sheep). The Black Sheep were at first the more powerful, and their chiefs Kara Yusuf (1388–1420) and Iskandar (1420–38) repeatedly occupied Azerbaijan and Mesopotamia. Nevertheless Shahrukh (1405–47) succeeded in time in reuniting most of Timur's empire under his rule. Unlike his father, he devoted himself to restoring some measure of prosperity and made his capital Herat the centre of a renewed and artistically brilliant Persian culture. He was succeeded by his only surviving son, Ulug-Beg (1447–49), formerly governor of

Samarkand; Ulug-Beg's name was made famous by the astronomical tables (*zij*) drawn up under his patronage, but in his time the Uzbek Turkmens began to challenge the Timurid government in Transoxiana. His murder was followed by further struggles among the Timurids, during which the Black Sheep under Jahanshah (d. 1467) extended their rule over Iraq, Fars and Isfahan (1453). Scarcely had Miranshah's grandson Abu Said established his power in the east than Jahanshah invaded Khurasan and seized Herat (1458), but the growing power of the White Sheep under Uzun Hasan brought about an agreement between Abu Said and Jahanshah to divide Iran between them. Defeated by the Ottoman Turks in 1461, Uzun Hasan turned against the Black Sheep and defeated and killed Jahanshah (1467), whose son appealed to Abu Said for assistance. Rejecting Uzun Hasan's overtures for peace, Abu Said marched into Azerbaijan and was defeated and killed (1469). The White Sheep were now supreme in the west, but were preoccupied with the growing Ottoman power, and the Timurids remained in possession of Herat, where the sultan Husain Bayqara (1468–1506) maintained a brilliant and luxurious court. After the deaths of Uzun Hasan (1478) and his son Yaqub (1490), the White Sheep confederacy began to break up, and western Iran and Iraq gradually became fragmented between petty governments, which opened the way to the conquests of the Safavids.

(X.)

VII. SAFAVIDS, 1501–1736

Shah Ismail I (*q.v.*), the founder of the Safavid (Safawid) dynasty, was sixth in descent from the saintly Sheikh Safi al-Din (1252–1334) of Ardabil, who had founded an order of Sufis there. Sheikh Safi claimed descent from the Prophet Mohammed through the imam Musa al-Kazim, the seventh of the imams or spiritual leaders of the Shi'a. Sheikh Safi and those of his descendants who succeeded him as the head (*pir* or *murshid*) of this order were greatly revered. They formed a theocratic form of government at Ardabil, ruling only as spiritual leaders. Their theocracy became so popular and influential that it excited the fears of Jahanshah, the Black Sheep chieftain who ruled over central and northwestern Iran from 1457 to 1467.

Sheikh Safi and his son and successor Sheikh Sadr al-Din were both Sunnis, but Sheikh Sadr al-Din's son Khwaja Ali, who succeeded to the headship of the order in 1399, adopted Shi'ism (*q.v.*) in a moderate form. His successor, Sheikh Ibrahim, became, however, imbued with extreme Shi'ite views, as was his son Sheikh Junaid who perished when fighting against the Sunnis of Dagestan (Daghistan) in 1455. Sheikh Haidar, who became head of the order on his father's death, gave to his followers, who were all Shi'ite Turkmens, the scarlet cap with 12 gores (one for each of the Shi'ite imams) which earned for them the nickname of Qizilbash ("Red Head"). Sheikh Haidar married Marta, the daughter of the White Sheep ruler Uzun Hasan and his Christian wife Despina Katerina, daughter of Kaolo Joannis, the penultimate emperor of Trebizond (Trabzon); by Marta Haidar had three sons and one daughter. Haidar, like his father, was a militant Shi'ite, and he was killed when fighting against the Sunnis in 1488, when his third son, Ismail, was only one year old. Ismail and his two elder brothers narrowly escaped capture by their enemies on a number of occasions. Eventually both the elder brothers were killed, leaving only Ismail, who thus succeeded to the headship of the Sufis of Ardabil. Ismail, by virtue of his position, won the support not only of the local Turkmens but also of many other tribes which had sought sanctuary in order to escape the persecution of the Ottoman Turks. With the aid of these tribes Ismail was able to capture Tabriz, where he was enthroned as shah of Azerbaijan in July 1501. In the course of the next few years Shah Ismail gained control over the greater part of Persia. He thereupon attacked the Sunni Uzbeks who had occupied part of northeast Persia and defeated them in a great battle near Merv in 1510. Despite the fact that many of his subjects had at the outset been Sunnis, Shah Ismail converted the majority to Shi'ism, which he made the state religion. He had even wider religious aspirations, a fact which brought him into conflict with Sultan Selim I (*q.v.*) of Turkey, a fanatical champion of Sunnism. The clash came at Chaldiran in northwest Persia in Aug. 1514. Though they fought with great bravery, Shah Ismail's tribal levies proved in the end no match for Selim's well-trained Janizaries and his corps of artillery. Selim followed up his victory by taking Tabriz, but a mutiny of his troops soon after forced him not only to relinquish it but to withdraw to Turkey.

The defeat at Chaldiran was a severe blow to Persian morale, but, on the other hand, Ismail was able thereafter to keep both the Ottoman Turks and the Uzbeks at bay and to retain the provinces of Baghdad and Mosul, which he had wrested from the former in an earlier campaign.

One of the consequences of Vasco da Gama's discovery of the sea route from Europe to the east by the Cape of Good Hope was the appearance of the Portuguese in the Persian gulf under the able leadership of Affonso d'Albuquerque early in the 16th century, when they captured the island of Hormuz and also made themselves masters of part of the adjoining mainland. Owing to his life and death struggle with the Ottoman Turks, Shah Ismail could do no more than make a protest to Portugal, but this aggressive action rankled not only in his mind but also in the minds of his successors.

Shah Ismail died, deeply regretted by his subjects, in 1524. During his reign he had welded his peoples into a nation; in this connection, the fact that he had made Shi'ism the dominant faith in Persia was of importance since the threat of attack by the Sunni powers on both the northwestern and northeastern frontiers served to knit the various racial elements together in defense of their common creed.

Tahmasp I and His Successors.—Shah Tahmasp (reigned 1524–76), Ismail's eldest son, was only 11 years old when he succeeded to the throne; he was thus for a number of years no more than a puppet in the hands of the powerful Turkmen chiefs. The early years of his reign were disturbed by repeated onslaughts of the Uzbeks and also by local revolts. Fortunately for Persia it was not until after these troubles had ceased that Sultan Suleiman I (*q.v.*) the Magnificent invaded Persia, capturing Tabriz and recovering the territory in Mesopotamia which Shah Ismail had conquered. The Turks soon relinquished their possession of Tabriz and withdrew to their own country, but in 1538 they renewed their onslaught, taking Tabriz again; once more, however, their possession of the Persian capital was brief. It was the proximity of Tabriz to the Turkish frontier which induced Shah Tahmasp to make Kazvin his capital in 1548.

In the course of Tahmasp's reign the western European powers were often hard-pressed by the Turks. The fact that the latter had a relatively strong and often hostile power on their eastern border was a factor of importance; on one occasion Augier de Busbecq, the emperor Ferdinand's envoy at Constantinople, remarked, "It is only the Persian who stands between us and ruin."

In 1561 the English merchant and traveler Anthony Jenkinson arrived at Kazvin bearing a letter from Queen Elizabeth to the shah, his object being to establish trade between England and Persia across Russia. Tahmasp received Jenkinson courteously, but brusquely bade him depart on discovering that he was a Christian.

When Shah Tahmasp died in 1576, Persia had grown appreciably weaker than it had been at the outset of his reign, one reason being that he had allowed the Turkmen chiefs to increase their power and influence. On the other hand, he had managed to prevent the Ottoman Turks and the Uzbeks from permanently alienating any of his territory.

On Tahmasp's death the crown passed to his elder son, Ismail, a drunken and dissolute tyrant who was poisoned after reigning for only a few months. His brother Mohammed Khudabanda, who succeeded him, was purblind and of weak character. The Turkmen chiefs took advantage of the situation to make themselves practically independent; when the Turks and Uzbeks once again invaded the country, they paid little or no heed to the shah's appeals for help.

Abbas I.—So serious did the situation become that a patriotic chieftain belonging to the Ustajlu tribe deposed Mohammed Khudabanda in 1587 in favour of his son Abbas (*see* ABBAS I, shah of Persia), who was then a youth of 16. The outlook for the

young monarch was most discouraging. Not only was much of his realm in the hands of the Turks and Uzbeks, but in the territory which remained free of their control the Turkmen tribes enjoyed a monopoly of military power. It being essential to break this military monopoly, Shah Abbas made a beginning toward this end by creating a special force which was paid directly from the royal treasury. Realizing that with his still very limited military strength he could not hope to contend successfully with both the Turks and the Uzbeks simultaneously, Shah Abbas made peace with the former on unfavourable terms in 1599 in order to concentrate on the latter. Fortunately for him, the Uzbeks were at that time weakened by internal dissensions, so the Persians' first onslaught on them was successful. The Uzbeks thereupon composed their differences and forced the Persians to evacuate Balkh, which they had occupied; they were unable, however, to renew their incursions into Persia. Early in 1599 the English adventurer Sir Anthony Sherley, his brother Sir Robert and a number of other Europeans arrived at the Persian court on an unofficial mission from the earl of Essex, with the object of inducing the shah to ally himself with the Christian powers against Turkey and to improve commercial relations between England and Persia.

As the trial of strength with Turkey had yet to come, Shah Abbas was most anxious to reform his army. By a fortunate chance, Sir Robert Sherley was a well-trained and capable soldier, and with his aid the shah formed three bodies of troops, all of whom were properly trained and armed and, moreover, were paid out of the royal treasury. One of these bodies of troops was a cavalry corps called the Qullar or "Slaves"; they were not in fact slaves, but were so called because they were recruited for the most part from Caucasia whence the Persians had for long been wont to take slaves. Like the Turkish Janizaries, the Qullar were mostly of Christian descent. The Tufangchis (musketeers) formed the second corps; they were at first infantry but were later converted into cavalry. The Topchis (artillerymen) formed the third corps. With his new army in being, Shah Abbas greatly reduced the strength of the Qizilbash levies and then, in 1603, he attacked the Turks. In this war his troops acquitted themselves brilliantly, proving more than a match for their formidable foes, with the result that Turkey had to relinquish the territory it had seized. Moreover, in a later campaign, Shah Abbas carried the war into Mesopotamia, capturing Baghdad. By his wise leadership and the valour and efficiency of his army, Persia's prestige was greatly enhanced. Although endeavours were made on more than one occasion to form a definite alliance between Persia and the western powers, these met with no success; but, as had previously been the case, the fact that Turkey had a strong military power on its eastern frontier curbed to some extent its activities in Europe.

Shah Abbas' reign was remarkable not only for his striking military successes but also for the efficiency of his administrative system, the magnificence of his court and his genius and zeal as a builder. Having made Isfahan his capital in 1598, he replanned and largely rebuilt it, endowing it with many splendid buildings such as the Masjid-i-Shah (*masjid*, "mosque"), the smaller but exquisite Masjid-i-Shaikh Lutfullah, the Ali Qapu and the Chihil Sutun; all these, with the exception of the Chihil Sutun, front onto the splendid Maidan-i-Shah or royal square. In consequence of Shah Abbas' endeavours, Isfahan became a worthy capital of his realm, rivaling even London in size (*see* ISFAHAN).

Shah Abbas fostered trade and industry in his new capital by settling many Armenians from the north of Persia in a new suburb called Julfa (Jolfa). He encouraged the English and Dutch East India companies to establish branches in Persia, giving them special trading facilities. He ruthlessly put down brigandage, making the routes once more safe for caravans and travelers; he also improved communications by constructing many bridges and caravansaries.

As Shah Abbas was an ardent nationalist, the Portuguese foothold in southern Persia was extremely irksome to him. In 1602 he expelled them from the mainland to the north of their trading centre on the island of Hormuz. Twenty years later, with the aid of the fleet of the English East India company, he ousted the Portuguese from Hormuz itself; to show his gratitude to the company he gave it valuable privileges at the port of Bandar Abbas (which was named after him).

In religion Shah Abbas was a zealous Shi'ite. As most of the holy cities of Islam were in the hands of the Sunni Turks, he urged his subjects to confine their pilgrimages to shrines of the imam Riza at Meshed and of his sister Fatima at Qom; he set them an example by performing the pilgrimage from Isfahan to Meshed on foot. Notwithstanding his religious zeal, Shah Abbas was most tolerant toward Christians, allowing the Carmelites and other orders to set up missions and build churches at Isfahan and elsewhere.

Although he had so many admirable qualities, Shah Abbas' character was marred by a cruel streak which manifested itself mostly against members of his own family. He not only blinded and imprisoned his father and his two brothers, but he also had his own son Mohammed Baqir Mirza executed and another son, Imam Quli, blinded.

Shah Abbas, unquestionably raised Persia from the depths of degradation to the status of a great power, yet he was nevertheless partly responsible for its subsequent decline by introducing the practice of immuring, for purposes of security, the heir apparent (as well as the other royal princes) in the harem, with the result that when the moment came for him to mount the throne he was totally inexperienced in the art of government. Shah Abbas died in Jan. 1629 at the age of 58, having reigned 42 years.

Decline of the Safavid Dynasty.—After the death of Shah Abbas the Safavid dynasty lasted for nearly a century, but, except for an interlude during the reign of Shah Abbas II (1642–66), it was a period of decline. One of the main reasons for this decline was the deterioration in the character of the sovereigns, which was due largely to the above-mentioned pernicious practice of incarcerating the heir apparent in the harem until the moment came when he had to succeed his father. In the circumstances, the court eunuchs obtained an undue measure of influence and power. As had been the case in Achaemenian times, this undoubtedly contributed to the decline of the dynasty. Shah Safi (1629–42) showed himself indifferent to affairs of state or the good of his country. He was cruel and bloodthirsty and he put to death many of his own relations as well as a number of the generals and statesmen who had greatly contributed to the glory of Shah Abbas' reign. Sultan Murad IV, the last of the Turkish warrior sultans, invaded Persia repeatedly, massacring the inhabitants of Hamadan and Tabriz and recovering Baghdad. Under Shah Abbas II Persia recovered some of its glory, and the pomp and pageantry of the court dazzled European envoys and travelers. Shah Abbas II's successor, Shah Suleiman, was a debauched tyrant, indifferent to the welfare of his people or to governmental affairs, and decline set in once more; it became accentuated under the pious but weak Shah Sultan Husain who ascended the throne in 1694. During his inglorious reign the control of affairs came more and more into the hands of the court eunuchs and the mullahs.

The first outward sign of impending disaster was the successful revolt of the Ghilzai Afghans of Kandahar in 1709 under the able leadership of their chief Mir Vais. He defeated the forces sent against him and ruled as an independent monarch until his death in 1715. In 1720 his son Mahmud raided Persia, penetrating as far as Kerman; he was then forced to return to Kandahar to quell a revolt there. In 1722 he again invaded Persia, once more taking Kerman. He then continued his advance. Although he was repulsed at Yazd, he marched boldly on Isfahan. Near the village of Gulnabad, 12½ mi. E. of the capital, the Afghans encountered the vastly superior Persian forces. Due mainly to bad leadership, the Persian troops were routed and fled in confusion back to the capital. Mahmud thereupon resumed his advance and invested the city, gradually cutting off all sources of supply from outside. In due course, famine set in and was followed by pestilence which took a terrible toll of the inhabitants. Tahmasp Mirza, the heir apparent, escaped from Isfahan with the object of raising a relieving force, but he failed to take any active steps to do so. Eventually, on Oct. 23, 1722, Isfahan surrendered and Shah Sultan Husain had to surrender his crown to his uncouth Afghan conqueror. As the Ghilzais were never in control over more than a portion of the

country, however, and as the Safavids were restored in 1729, the dynasty may be regarded as continuing until its complete suppression seven years later.

Peter the Great of Russia had for long been contemplating the establishment of a trade route to India across the Caspian sea and the countries beyond. The losses sustained by some Russian merchants in northern Persia in the course of a tribal uprising there in 1721 gave him the pretext for invading that country in the following year. Peter's action alarmed the Turks, who likewise invaded Persia in order to prevent Russia from gaining control over the territories contiguous to their country. For a time war between Turkey and Russia seemed imminent, but a settlement was reached in 1724 when the two powers agreed to partition much of Persia between them, Russia taking part of the northern provinces while Turkey occupied the northwest and west portions. Mahmud, the Ghilzai usurper, was left in possession of central and part of southwestern Persia, while the remainder of the country was in loyalist hands.

Mahmud died or was put to death in 1725 and was succeeded by his more capable cousin Ashraf. Although he held the capital and its district, Shiraz and other parts of southern and southwestern Persia, his position was most insecure, as his Afghan troops were greatly outnumbered by those who remained loyal to the Safavids. The Afghans were detested by the Persians on racial grounds and also because they were stanch Sunnis. Tahmasp Mirza, who had proclaimed himself shah on hearing of his father's deposition, was gathering troops in the northeast, and Russia and Turkey were determined to retain the Persian territories they had seized. As Peter the Great had alleged that he would endeavour to restore the Safavid dynasty, Ashraf remonstrated with Turkey for allying itself with Russia, a Christian power, in order to deprive him, a Sunni ruler, of his throne in favour of a Shi'ite claimant. Ashraf's arguments met with some favour in Turkey, but the latter nevertheless declared war on him. Ashraf, by skilful propaganda, undermined the morale of the Turkish troops and won a victory over them. By his studied moderation after his military success and by his appeal for unity among Sunnis, he made peace with Turkey on relatively favourable terms, being recognized as shah of Persia. Turkey, however, refused to cede to him any of the provinces it had occupied.

Nadr Quli Beg.—Ashraf was no sooner freed from the Turkish menace than he was confronted with another danger the serious nature of which he failed at first to realize. Tahmasp Mirza was at this juncture joined by Nadr Quli Beg, a member of the Afshar tribe and former leader of a band of robbers. Nadr Quli Beg brought with him 5,000 Afshars and other tribesmen to whom he had already given some military training. In gratitude for his adhesion, Tahmasp Mirza gave Nadr Quli Beg the title of Tahmasp Quli Khan. Tahmasp Mirza had already obtained the support of 3,000 Qajar tribesmen under their chief Fath Ali Khan. Both Tahmasp Quli Khan and Fath Ali Khan were intensely ambitious men, and a keen struggle for supremacy immediately ensued. This struggle ended in Tahmasp Quli Khan's favour when Tahmasp had his rival executed on a charge of treason.

Tahmasp Quli Khan soon showed that he was a soldier of genius. He took great pains to train the prince's forces, inspiring them with confidence not only in him but also in themselves. Deeming the Ghilzai Afghans too formidable to be attacked by his still only partially disciplined men, he first led them against rebels who had set themselves up as independent rulers in Meshed and Herat, in both cases achieving complete success.

Meanwhile, Ashraf, having at last become aware of his danger, marched eastward to attack Tahmasp Mirza and his formidable general. In a series of brilliant victories, Tahmasp Quli Khan defeated and almost annihilated the Afghans; on the recovery of Isfahan in 1729, Tahmasp was able at last to ascend the throne. Tahmasp Quli Khan then attacked the Turks and drove them out of most of the territory they had occupied; a revolt in Khurasan prevented him, however, from completing their expulsion. In his absence in Khurasan, Shah Tahmasp rashly attacked the Turks; having sustained a heavy defeat, he had to make peace on humiliating terms. Tahmasp Quli Khan hastened back from Khurasan, deposed Tahmasp and placed the latter's infant son Abbas on the throne. He thereupon resumed the war with Turkey, retrieving the provinces lost by Tahmasp and completing the expulsion of the Turks from Persia. By threatening war, Tahmasp Quli Khan made Russia relinquish its conquests in Persia.

In the spring of 1736 Tahmasp Quli Khan felt himself strong enough to cast all pretense aside, deposing Abbas III and mounting the throne himself; on so doing, he took the title of Nadir Shah (*q.v.*).

VIII. AFSHARIDS, 1736–49

Nadir Shah had successfully dealt with both the Turks and the Russians, having previously shattered the Ghilzai Afghans. Nevertheless, the Ghilzais, under Husain, Mahmud's brother, still maintained themselves in the province of Kandahar, a fact which made Nadir determined to attack them. Husain had ample warning of Nadir's intentions and had accumulated large stocks of provisions and military stores. The fortress of Kandahar, moreover, was very strong. As Nadir had no siege artillery, a long blockade followed the investment of the fortress. For many months the siege went on, great damage being done to the defenses; at length, after nearly a year had elapsed, Kandahar fell. Nadir treated the survivors of the garrison with moderation and enlisted many of them in his army. With the capture of Kandahar and the subjugation of the surrounding district, the recovery of the lost provinces of Persia was complete.

Indian Campaign.—Nadir, who was an intensely ambitious man, was not satisfied with this achievement, great though it was. For some years past, the lure of India and its incalculable wealth had had him in thrall. It so happened that the Mogul dynasty, like that of the Safavids, had for some time been on the decline, and Mohammed Shah, the degenerate descendant of Babur and Akbar, and his imbecile ministers were not the men to be in control of a vast empire at a time of serious crisis. As soon as Nadir could complete his preparations after the fall of Kandahar, he and his well-trained veterans set out on their eastward march. After capturing Kabul, Nadir pressed onward, but found the Khyber pass held in force by the Indian troops. Nothing daunted, Nadir traversed the mountains by the parallel Tsatsobi pass and attacked and routed the Indians from the rear. The Persian forces then resumed their advance, capturing Peshawar and crossing the Indus without meeting serious resistance.

Meanwhile, Mohammed Shah had at last realized the danger confronting him. He and his main forces marched from Delhi to Karnal, 70 mi. to the north, where they formed a strongly entrenched camp in which to await the oncoming enemy. Nadir, when his army drew near, realized the strength of the Indian position, and decided to give battle only if the emperor's forces emerged; if they failed to do so, he would march directly on Delhi. At this juncture, Sa'adat Khan, the subahdar of Oudh, joined Mohammed Shah with 30,000 men. Hearing a report that the Persians were plundering his baggage, Sa'adat Khan impetuously attacked them, but was lured into a trap, defeated and taken prisoner. Part of the emperor's forces who had gone to Sa'adat Khan's assistance then became involved with the Persians. In the battle which ensued Nadir's forces obtained a complete victory. He thereupon surrounded the Indian camp and cut off all supplies.

Mohammed Shah, knowing that his troops would not fight again and that supplies would soon be exhausted, surrendered. Nadir treated him outwardly with respect but in reality made him and his nobles prisoners. In company with the luckless emperor, Nadir thereupon marched in triumph to Delhi, which he entered in March 1739. He then proceeded to strip the emperor and his people of their treasures, obtaining, it is said, booty to the value of Rs. 700,000,000. As the Indian historian Anand Ram Mukhlis remarked, "the accumulated wealth of 348 years changed owners in a moment."

Nadir remained for two months in Delhi. He put down with such terrible severity a rising of the citizens against his troops that a *nadir-shahi* is still synonymous there with a massacre. After this tragic event, Nadir demanded and obtained the hand of a granddaughter of Aurangzeb for his second son, Nasrullah Mirza.

When, in accordance with Mogul etiquette, inquiries were made as to Nasrullah's descent to the seventh generation, Nadir said: "Tell them that he is the son of Nadir Shah, the son of the sword, the grandson of the sword, and so on until they have a descent of 70 instead of seven generations."

Realizing that he could not hold Delhi, Nadir restored it and the bulk of the empire to Mohammed Shah, but he annexed the provinces on the right bank of the Indus, which during the reign of Darius had been incorporated in the Achaemenian empire. Then, after a stay of less than a year, he returned to Persia with greater power, wealth and glory than any other Asian conqueror since Timur.

Campaign Against Bukhara and Khiva, 1740.—During the siege of Kandahar, Nadir had dispatched Reza Quli Mirza, his eldest son and heir, against Balkh, whose ruler had promised help to Husain, the Ghilzai ruler. The prince had proved himself worthy of the command and succeeded in taking the city. He then crossed the Amu-Darya river and defeated a strong force of Uzbeks. Nadir, who was unwilling to attack Bukhara at that juncture, then recalled Reza Quli. After the Indian campaign the situation, however, was completely changed. Nadir had not forgotten the raids made on Khurasan by the Turkmens of Khiva, and he realized that a campaign against the two Uzbek states would form a natural corollary to the conquest of India, besides protecting Khurasan against Turkmen raids for some time to come. Large quantities of grain had been collected at Balkh and loaded into boats, and the expedition then began its march down the Amu-Darya to Charjui (Chardzhou) where a crossing was made by means of a bridge of boats. The amir of Bukhara, realizing that he could not hope to resist Nadir's veterans, promptly submitted and went to the Persian camp. There he was at first treated with disdain, but Nadir finally restored him to the throne on condition that the Amu-Darya should again form the boundary of Persia and that the amir should supply a contingent of troops for the Persian army.

After Bukhara it was the turn of Khiva. On learning of Nadir's approach, Ilbars, the khan of Khiva, set out to destroy the bridge of boats at Charjui, but Nadir forestalled him and routed his forces. Taking his supplies by boat down the Amu-Darya, Nadir pursued Ilbars along the river bank and decisively defeated him near Khiva. Soon afterward Ilbars surrendered. As he had put to death the envoys whom Nadir had sent to him before the campaign, the conqueror executed him together with 30 of his councilors. At Khiva Nadir found two Englishmen who were members of the staff of Jonas Hanway, the intrepid merchant who endeavoured to establish trade between Persia and central Asia across Russia and who has left a most valuable account of the state of Persia at this time. Nadir treated the Englishmen kindly, giving them passports and promising them compensation for their losses. One result of this campaign was the release of thousands of Persian and Russian slaves; furthermore, the crushing of the Khivans stopped for some time their incursions into Persian territory.

Nadir was now at the zenith of his fame. Not only had he driven all Persia's foes from its soil, but he had made its territories more extensive than those of the Safavids. Through him Persia was once again a great military power. Had he possessed any foresight and any real concern for his people, he would have abandoned all further idea of war and conquest and so would have enabled Persia to become prosperous and settled. Nadir, however, had no administrative capacity or thought for the well-being of his people; he lived only for war.

While Nadir was besieging Kandahar, Ibrahim Khan, his only brother, who was in command of the forces in northwestern Persia, having heard of the successes of his nephew Reza Quli Mirza in Turkistan, wished to emulate them. He rashly attacked the formidable Lezgian tribe, but lost his life in so doing. Nadir, on learning of this disaster, felt bound to avenge his brother. He accordingly set out for Dagestan; on his way, he was shot at and slightly wounded. Like Shah Abbas, Nadir was jealous of his eldest son, whom he unjustly suspected of having instigated this attempt on his life. He subsequently had the unfortunate prince blinded. The prince reproached his father, saying, "It is not my eyes but those of Persia which you have put out."

At the outset of Nadir's campaign against the Lezgians all went well, but the main bodies of these hardy and warlike tribesmen retreated to the densely wooded higher country where conditions were ideal for ambushes and surprise attacks. The result was that the Persian troops were repeatedly defeated, suffering heavy loss. These reverses infuriated Nadir, but despite the utmost efforts of his troops, the stubborn Dagestanis more than held their own and eventually forced him to retreat baffled and sullen. At the close of the campaign Nadir found himself with an exhausted and depleted army and with his prestige much impaired.

The success of the Lezgians caused revolts to break out in various parts of the country, but Nadir suppressed them with merciless severity. He had unwisely endeavoured to reunite Islam by making his people abjure Shi'ism and join the Ja'fari sect, which he intended to be a fifth sect of the Sunnis. At the time his subjects did not openly object to the change, but it was nevertheless most unpopular. Moreover, in Turkey it met with a hostile reception, the religious leaders there giving the following decision: "The new sect is contrary to the true belief, and it is permissible to kill the people of Persia." This decision was followed by the invasion of Persia by an enormous army, which was determined to avenge former defeats. Nadir, however, as great a general as ever, inflicted a crushing defeat on the Turks, capturing the whole of their artillery and stores. Negotiations for peace followed in the course of which Nadir agreed to abandon his claim to found a new sect and to release his prisoners. This was his last victory.

Death of Nadir Shah, 1747.—During the last few years of his life Nadir became increasingly savage and cruel, being subject to sudden outbursts of rage. In these paroxysms he put to death so many of his officers and advisers that no one felt safe. The consequence was that he was assassinated in his tent one night when endeavouring to suppress a revolt in Khurasan. Thus ended the career of Nadir Shah, who, endowed with superb physique, a voice of thunder, dauntless courage and a real genius for war, had hewn his way to the throne. As in the case of Napoleon, with whom he may be compared, success had caused moral deterioration, and when he died the nation which he had saved from the Afghans, Turks and Russians received the news with intense relief. Had the attempt on his life in 1741 been successful, he would have been the national hero for all time.

Nadir's assassination was the signal for the breakup of his composite army. Ahmad Khan Abdali and his Afghans, who had remained loyal to Nadir to the last, marched off to Kandahar. On the way Ahmad had the good fortune to intercept a Persian treasure convoy. He thereupon marched on and founded the kingdom of Afghanistan, taking the title of Ahmad Shah Durrani. The Persian throne was seized by Nadir's nephew Ali Quli Khan, who took the title of Adil Shah. His reign was very brief, as he was soon deposed and blinded by his brother Ibrahim. The new shah attempted to seize Shahrukh, the son of the ill-fated Reza Quli Mirza, but failed to do so. Not long afterward Ibrahim was killed by his own troops, and Adil Shah also lost his life at this juncture. Shahrukh was then made shah, but in Dec. 1749 he was supplanted and blinded by a Safavid claimant, who styled himself Suleiman II.

At this juncture the Afsharid dynasty may be said to end; although Shahrukh was reinstated by Ahmad Shah Durrani after the brief rule of the Safavid usurper (who was himself deposed and deprived of his sight after ruling for only 40 days), his authority, such as it was, was limited to Khurasan which was for many years merely an appanage of Afghanistan.

Meanwhile, a stern triangular contest for control over the rest of Persia had developed, the aspirants for power being Karim Khan, of the Zand tribe of Fars; an Afghan general named Azad Khan; and Mohammed Hasan Khan, a son of Fath Ali Khan Qajar whom Tahmasp had put to death in 1726. Victory went first to one and then to another of the three claimants until, after Mohammed Hasan Khan had been killed and Azad Khan had surrendered, Karim Khan was left supreme.

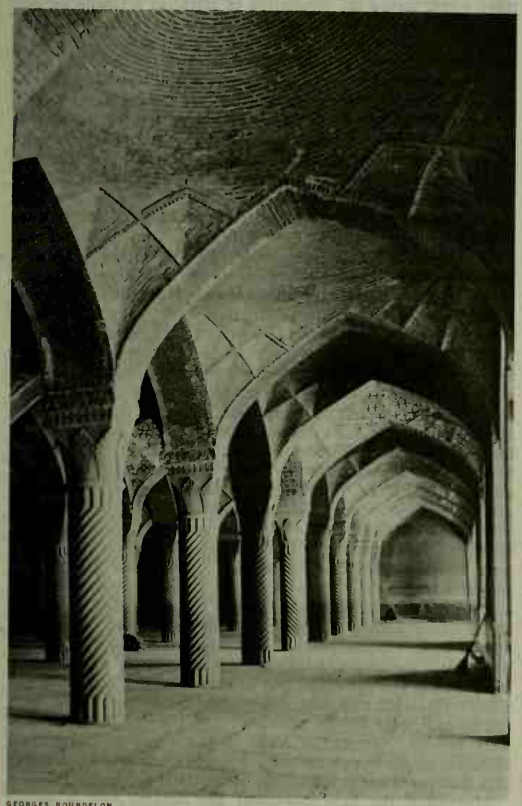
IX. ZAND DYNASTY, 1757–94

Karim Khan, a man of humble birth, had served in Nadir's army, without, however, achieving any distinction as a leader. He owed his popularity to his probity, his tolerant views and his kindliness. Under his rule Persia enjoyed a much-needed period of peace and justice, with the result that there was some return to prosperity. He never styled himself shah, being content with the title of *vakil* (regent). Being a man of the south, he made Shiraz his capital and adorned it with many noble buildings and beautiful gardens.

Persia's period of peace and prosperity was ended on Karim Khan's death in 1779, when various members of the Zand family strove for the succession. For a number of years one of the hostages at Karim Khan's court was Agha Mohammed Khan Qajar, a son of Mohammed Hasan Khan. When very young he had fallen into the hands of Adil Shah, who had made him a eunuch, a cruel act which permanently warped his character. When Agha Mohammed learned that Karim Khan was *in extremis*, he escaped from Shiraz and hastened to the Qajar tribal country in the northeast where he gathered together a strong force. Subsequently, he gained over to his side Hajji Ibrahim, the redoubtable vizier of the Zand family, with whose help he was able to defeat and capture the gallant Lutf Ali Khan, the last of the Zand dynasty, whom he most cruelly tortured and put to death.

X. QAJAR DYNASTY, 1794–1925

Agha Mohammed Shah.—Agha Mohammed owed his success not so much to his generalship as to his statesmanship and guile.



GEORGES BOURDELON

PRAYER ROOM IN THE HAKIL MOSQUE, SHIRAZ; THE CITY WAS EMBELLISHED BY KARIM KHAN IN THE 18TH CENTURY

As Hajji Ibrahim remarked after his death, "That monarch's head never left work for his hand." As pointed out, his mutilation when a mere youth had left a permanent mark on his character, making him vindictive and inordinately cruel.

After Agha Mohammed's final defeat of his rival, he attacked King Erekle (Heraclius) II of Georgia who, after Nadir Shah's death, had declared the independence of his country and had annexed territories extending southward to the Aras river. He had subsequently placed Georgia under the protection of Russia. Agha Mohammed acted so swiftly that he was able to defeat Erekle in the field and capture and sack Tbilisi (Tiflis) before Russia could respond to the Georgian ruler's appeal for aid. Agha Mohammed then evacuated Tbilisi and returned to Teheran which he had made his capital city.

In the spring of 1796 Agha Mohammed, yielding with feigned reluctance to the pleadings of his courtiers, had himself enthroned in Teheran. Almost immediately after the ceremony the shah set out for Khurasan, where Shahrukh still held his pathetic court. Being unable to offer resistance, Shahrukh submitted, but Agha Mohammed had a further motive; he knew that the prince had in his possession many of the priceless jewels which his grandfather had looted in Delhi in 1739. He thereupon subjected the prince to torture, forcing him gradually to give up his treasures. Finally, after Aurangzeb's famous ruby had been extorted in this way, Shahrukh, worn out by his sufferings, fell ill and died, cursing the Qajar monarch.

Agha Mohammed had intended to attack Bukhara after attaining his object in Khurasan, but, on learning that the Russians had invaded northern Persia, he hastened westward with his forces to oppose them. The Russians succeeded in taking Derbent and Baku but failed to capture Enzeli. Later they entered Shamakhi, in Shirvan, and were thus in a position to threaten Azerbaijan when the news of the death of the empress Catherine caused them to withdraw.

In the spring of 1797 Agha Mohammed Shah set out for Georgia to attack Erekle again. Before he came to grips with the Georgians, he was murdered in his tent by two of his servants whom he had sentenced to death for some trivial offenses but had nevertheless allowed to continue in attendance on him. Thus died the founder of the Qajar dynasty (*q.v.*), who had made himself detested and feared by all his subjects.

Fath Ali Shah.—The assassination of Agha Mohammed Shah was followed by a struggle for the throne which ended with the triumph of his nephew Fath Ali (reigned 1797–1834), a man of very different stamp. He was in general kindly and humane, though he could on occasion be capricious and cruel. It was during his reign that Persia, due to its position on the overland route to India, became involved in the rivalries of European powers. In 1798 Zaman Shah, the amir of Kabul, invaded India, advancing as far as Lahore. Lord Wellesley, the governor general, sent an envoy to Teheran to request the shah to take any steps short of war to curb the ambitious amir. Zaman Shah at this juncture demanded the cession of Khurasan by Persia, which led Fath Ali Shah to co-operate with the British by sending military aid to two Afghan pretenders; the amir thereupon withdrew his forces from Indian soil. Hardly had this danger to India been averted when what appeared to be a far more ominous menace developed. Napoleon and his Russian ally, the emperor Paul, planned to invade India jointly, by way of Persia. Although in the light of modern knowledge of the territories concerned it is clear that the scheme would have been impracticable, it was taken seriously at the time. Lord Wellesley sent Captain (later Sir John) Malcolm to Teheran, at the head of an imposing mission, to take all possible steps to persuade the shah to put pressure on the amir of Kabul to counteract the French designs and to negotiate a political and commercial treaty. Malcolm, who conducted the negotiations in an able manner, obtained the desired assurances from the shah and concluded a political and commercial treaty with him. Unfortunately, when Malcolm returned to India, no one was sent to replace him at the Persian court.

The murder of the emperor Paul in 1801 removed the danger of a joint Franco-Russian attack on India, but the threat from France

remained. In Dec. 1801 Russia formally annexed two provinces of Georgia and four years later declared war on Persia, taking Derbent and Baku. As the government of India failed to respond to the shah's appeals for help, he turned, but with some reluctance, to France (he had for long been unwilling to become the ally of a nation which had put its own monarch to death). By the treaty of Finkenstein, signed in May 1807, France undertook to help Persia to recover the provinces of Georgia and the other territories which Russia had seized. Almost immediately afterward, Napoleon made peace with Russia, with the result that the treaty of Finkenstein became a dead letter. Persia therefore received no help in its struggle with Russia, which ended disastrously in 1813 with the conclusion of the treaty of Gulistan (Golestan). By this treaty Persia had to renounce all claim to Georgia and to cede Qareh Dagh, Ganja (Kirovabad), Shirvan, Derbent and Baku. In 1814 the British government concluded a treaty with Persia whereby the latter agreed not to sign treaties or to cooperate militarily with countries hostile to Great Britain; in return Persia was to receive a subsidy of £150,000 a year, which would cease if Persia engaged in a war of aggression. What the British government failed to realize was that, while the French peril was a thing of the past, Persia's enforced cession of territory to Russia under the terms of the Gulistan treaty had created an entirely new situation.

Owing to ambiguous wording, the treaty of Gulistan led in 1825 to a dispute between Persia and Russia concerning three districts. While negotiations were in progress, Russia arbitrarily occupied these districts, an act which so stirred Persian public opinion that the shah had to declare war (1827). At the outset the Persian forces carried all before them, recovering much of the lost territories. Due to the parsimony of Fath Ali Shah, most of his troops had to be disbanded when the shah refused to pay them during the winter. Russia then gained the upper hand and forced Persia to conclude peace on ignominious terms by the treaty of Turkmanchai (Torkaman) in 1828. By this treaty, Persia had to cede Erevan (Yerevan) and Nakhichevan, besides giving up all claim to Georgia and the other areas lost in the earlier war. Persia was forced to pay a heavy indemnity and to grant extraterritorial rights to Russian nationals on Persian soil. By a commercial treaty concluded at the same time, Persians in Russia and Russians in Persia were to be allowed to export and import goods on payment of an ad valorem duty of 5%. These treaties inaugurated a new era and became the basis on which other European nations conducted their intercourse with Persia. Great Britain recognized the changed position; moreover, as Persia had been the aggressor in the war, Britain refused to continue the subsidy.

Fath Ali Shah realized that his country's defeat by Russia was final. He thereupon turned his attention eastward in order to endeavour to regain the territories which had been lost there. The prospects did not seem unpromising, as the Durrani dynasty had greatly declined since the death of its founder, Ahmad Shah. The shah sent Abbas Mirza, the heir apparent and commander in chief of the royal forces, to Khurasan to restore the situation there before attacking the Afghans. Abbas Mirza successfully attacked the Turkmens, who, although aided by the khan of Khiva, were effectively subdued. Abbas Mirza thereupon summoned Kamran, the nominal Sadozai ruler of Herat, to submit, but Abbas Mirza died before he could lead his main forces against Kamran. Mohammed Mirza, Abbas Mirza's eldest son, had meanwhile laid siege to Herat, but withdrew his army and hastened to Teheran when the news of his father's death reached him. Not long afterward Fath Ali Shah died, aged 63, having reigned for 37 years. It was his misfortune that his reign coincided with the rivalry of France, Great Britain and Russia over eastern affairs and with the revival of Russia's *Drang nach Osten*, which Peter the Great had inaugurated a century earlier.

Mohammed Shah.—Fath Ali Shah's successor was his grandson Mohammed Mirza, but his accession was disputed by several rival claimants to the throne. His bid for the throne succeeded because of the skilful handling of his troops by their commander, Sir Henry Lindesay-Bethune.

Mohammed Shah (reigned 1834–48) was obsessed with the desire to win military renown, but he was sensible enough to realize that he could not hope to do so if he resumed hostilities with Russia. With the active encouragement of the Russian minister, the shah determined to resume operations against Herat. Great Britain, anxious as ever to protect India, endeavoured, but without success, to dissuade Mohammed Shah. Great Britain feared that if Persia conquered the province of Herat and possibly additional territory to the east, Russia would be able, in virtue of the treaty of Turkmanchai, to appoint consuls in those regions and so extend its influence both commercially and politically almost to the Indian frontier. At this juncture a British military mission reached Teheran, but the shah received it with coldness and pressed on with his plans. In 1837 the Persian forces began the siege of Herat. Yar Mohammed, Kamran's able vizier, had had ample warning of the shah's intentions and had not only repaired the fortifications but had also laid in large stocks of food and munitions; moreover, Eldred Pottinger, a British artillery officer, opportunely arrived on the scene and gave valuable help to the besieged forces. In the spring of 1838 Sir John McNeill, the British minister, reached the Persian camp and endeavoured to persuade the shah to raise the siege. The shah, however, preferred to follow the advice of Count Simonich, the Russian minister, whose aide-de-camp proceeded to direct the siege operations. McNeill, being thus flouted, left the Persian camp. Soon after the envoy's departure, the shah's forces made their final assault, but it was repulsed with heavy loss. The shah was very dejected at this costly failure; consequently, when he received a communication from the British minister that the British government would regard the occupation of Herat as a hostile act and that British troops had already occupied the island of Khark (Kharg) in the Persian gulf, the shah broke off the siege. The last few years of Mohammed Shah's reign were troubled by the revolt of the Aga Khan, the spiritual leader of the Isma'ilis, a dispute with Turkey and disturbances caused by the Babi movement. The Aga Khan's revolt was crushed and he was forced to take refuge in India. The dispute with Turkey was settled by the joint intervention of Great Britain and Russia, but the Babi movement remained unsuppressed. The founder of this movement was Mirza 'Ali Mohammed, the son of a merchant of Shiraz, who, after long meditation and having performed the pilgrimage to Mecca, proclaimed himself to be the Bab (gateway) to the Divine Truth. The Babi movement rapidly gained strength in the years that followed, despite the imprisonment of the Bab himself in 1847 (*see* BAB; BABISM). In the following year Mohammed Shah, who had for long been in failing health, died.

Nasir ad-Din Shah.—Nasir ad-Din (*q.v.*; reigned 1848–96) was only 17 when he succeeded his father. Though so young, he had for several years been governor general of Azerbaijan (it was customary in the Qajar period for the heir apparent to hold that position), and he brought with him from Tabriz his remarkably able and scrupulously honest minister Mirza Taqi Khan, whom he made his vizier. With this minister's aid some serious disturbances which had broken out on the death of Mohammed Shah were quelled. Taqi Khan, who had been impressed by the liberal movement in Turkey, induced the shah to introduce some much-needed reforms. For the first time for many years the army was regularly paid and the sale of offices, titles and justice was stopped, as were also a number of other abuses. Taqi Khan was also responsible for the founding of the École Polytechnique in Teheran and for the publication of the first Persian newspaper. Unfortunately, Taqi Khan's reforms made him a number of enemies, among whom was the queen mother, whose influence over her son was great. She alleged to the shah that his minister was becoming too powerful and persuaded him to have him put to death. Taqi Khan's execution had most unfortunate results for Persia, as it put an end to the reform movement and many of the old abuses were revived. Thereafter Nasir ad-Din ruled as an absolute monarch, but he was on the whole a more enlightened and humane man than his father or indeed any of his Qajar successors.

Meanwhile, the Babi movement had become such a serious menace that the Bab himself was executed in 1850. Two years later an unsuccessful Babi attempt to assassinate the shah led to

such a fierce persecution of the sect that most of the survivors fled the country. The Baha'i faith (*q.v.*), an offshoot of the sect founded by the Bab, still exists and has many followers not only in Persia, but also in the Levant and the United States.

Nasir ad-Din was, like his father, desirous of obtaining compensation for the territorial losses to Russia in northern Persia earlier in the century by conquest in the east, Herat being as before the primary objective. These aspirations were encouraged by the Russian minister at Teheran. Yar Mohammed, Kamran's capable vizier, had died, leaving the government of the province of Herat to his imbecile son, whose first action was to open up negotiations with Persia. Great Britain thereupon protested and imposed a treaty on Persia whereby the Persian government undertook not to send troops to Herat unless that province were attacked from outside. Notwithstanding this undertaking, Persia subsequently gained possession of Herat (1856) through an Afghan nominee. Great Britain thereupon seized the island of Khark again and landed an expeditionary force under Sir James Outram near Bushire. This force marched inland and defeated a strong body of Persian troops; it then withdrew to the coast, crossed the head of the Persian gulf, sailed up the Shatt al Arab and captured Mohammerah (Khorramshahr). Meanwhile, unknown to both the belligerent forces, Britain and Persia had concluded the treaty of Paris (1857) whereby the shah undertook to evacuate Herat and to recognize the kingdom of Afghanistan.

As already stated, Russia, earlier in the century, had enveloped Persia on the north. Moreover, in the reign of Mohammed Shah, it had established a naval base on the island of Ashurada in the southeast corner of the Caspian sea in order to keep the piratical Turkmens in check. An attempt to subdue the khanate of Khiva, however, failed. The serious revolt in the Caucasus, together with the Crimean War, prevented Russia from pursuing its expansionist policy in central Asia for a number of years. Once freed from these difficulties, however, Russia resumed its advance, subduing the khanates one by one. In 1881 Gen. Mikhail Skobelev stormed Geok-Tepe, the stronghold of the formidable Tekke Turkmens, and three years later Russia completed the conquest of central Asia by the occupation of the Merv oasis. Persia thus found itself enveloped by Russia on the northeast as well as on the north.

Meanwhile, trouble had arisen between Persia and Afghanistan over Seistan. This question was settled in 1872 by the Seistan Arbitration commission, the province being divided between the two countries. Subsequently, the frontier between Persia and British Baluchistan was satisfactorily settled.

Through the influence of the enlightened Mirza Taqi Khan, Nasir ad-Din had become imbued to some extent with liberal ideas, but the failure of the constitutional movement in Turkey and Sultan Abdul-Hamid II's reversion to autocratic rule in 1878 discouraged the Persian liberals and caused the shah to modify his views, with the result that he became strongly opposed to reforms in his later years. Nevertheless, some progress was made during his reign toward the modernization of Persia in a number of ways, such as the introduction of the electric telegraph and a postal system, the establishment of a college in Teheran where science and other subjects could be studied on modern lines, the growth of the press and the construction of roads for wheeled traffic. It was greatly to Nasir ad-Din's credit that he established security throughout his realm. He was able to leave his country and visit Europe in 1873, 1878 and 1889. Although he was in general kindly, he could be stern and cruel at times; he was for most of his reign liked and respected by his subjects and he was, without question, the best of the Qajar sovereigns. In his later years, however, he lost his popularity partly because of his action in granting concessions to foreigners more with the object of pecuniary gain for himself than for the development of his country and partly because of his refusal to accede to the growing demand for reforms. He was assassinated in May 1896 four days before the 50th lunar anniversary of his accession.

Muzaffar ad-Din.—Nasir ad-Din was succeeded by his son Muzaffar ad-Din (reigned 1896–1907). Though not unkindly by nature, the new shah was of weak character and lacking in initiative. He suffered much from ill health and made this the excuse for costly journeys to Europe; his extravagance and that of his court brought the country to the verge of bankruptcy. After his accession the agitation for reforms grew rapidly in intensity. One of the chief leaders of the popular movement was Jamal al-Din al-Afghani (*q.v.*), an extremely able man who had gained considerable influence in the closing years of the previous reign. He was a pan-Islamist rather than a constitutionalist (*see* PAN-ISLAMISM). Another prominent leader was Malkom Khan, who was for many years Persian minister in London. Like Jamal al-Din, he was a great enemy of Amin as-Sultan, the shah's chief minister. He published in London a paper entitled *Qanun* in which he advocated the promulgation of a code of laws and other reforms; this paper, though officially banned in Persia, nevertheless had a wide circulation there.

In 1905 a number of merchants, in protest at the extravagance of the shah, the misgovernment and corruption of his ministers and the introduction of an onerous customs tariff, following an ancient custom, took *bast* (sanctuary) in one of the mosques in Teheran, where they were joined by some mullahs. On being expelled from this mosque, they went to the shrine of Shah Abdul-Azim, a few miles to the south of the city. When efforts to disperse them failed, the shah promised to dismiss the chief minister and to convene an *adalat-khaneh* ("house of justice"). The *bastis* thereupon dispersed, but the shah failed to implement his promises, whereupon many of the ulema went to Qom and threatened to go from there to Mesopotamia.

In consequence of further acts of oppression by the government, a large number of persons, including merchants, bankers and members of the ulema, took *bast* in the grounds of the British legation whence they renewed their demands for the dismissal of the obnoxious minister, the promulgation of a legal code and the recall of the ulema from Qom. Though the shah yielded to the extent of dismissing the unpopular minister, the people persisted in their demands, which included for the first time a request for a constitution. With great reluctance the shah complied with this last demand, with the result that in Oct. 1906 the first *majlis* (national consultative assembly) was convened. A committee of members was then formed which drafted the Fundamental Law of the constitution. This law was signed by the shah, who was by then moribund, on Dec. 30, 1906. Five days later he died.

The achievement of the constitutionalists was a truly remarkable one; except for the few reactionaries who continued to support the shah, practically the whole nation took part in the struggle. Although it ended in failure, the attempt by the Russian constitutionalists to end the autocratic rule of the tsar had a considerable effect on Persian public opinion, particularly in Azerbaijan.

Mohammed Ali.—Mohammed Ali (reigned 1907–09), Muzaffar ad-Din's eldest son, succeeded his father; he was aged 34. While governor general of Azerbaijan, he had shown himself bitterly opposed to the movement for reform. Although on his accession he took a solemn oath to preserve the independence of the country and the rights of the people and to observe the Fundamental Law of the constitution, he speedily showed that he had no intention of abiding by it. He was forced, however, by popular clamour to agree to the drafting of a supplementary Fundamental Law, to reaffirm that Persia had a constitution and to dismiss the Belgian head of the customs administration who had made himself most unpopular.

The able but reactionary Amin as-Sultan, who had been exiled, was recalled at this stage and reinstated as vizier, with the object of undermining and finally destroying the constitution. He endeavoured to persuade the moderate party in the *majlis* to agree to the raising of a loan to replenish the empty treasury, and might have achieved this object had he not been assassinated at the end of Aug. 1907. Pressure of public opinion forced the shah to appoint the liberal-minded Nasir al-Mulk as his successor, but, apart from inducing the shah to sign the supplementary Fundamental Law of the constitution in Oct. 1907, he could achieve little or nothing in the way of reforms.

Meanwhile, on Aug. 31, 1907, the Anglo-Russian agreement had

been signed which was designed to settle all differences between Great Britain and Russia insofar as Tibet, Afghanistan and Persia were concerned. As regards Persia, this agreement divided the country into three zones for commercial development; Russia was allocated the north and centre and Great Britain the southeast, which consisted almost entirely of deserts. The southwest of the country was declared neutral; from the British point of view the creation of this area as a neutral zone was a serious error, in view of the subsequent discovery of oil and its enormous development there by the Anglo-Persian Oil company. Russia had undoubtedly the better of the bargain. In this agreement the two powers, after affirming their respect for the independence and integrity of Persia, stipulated that neither should seek concessions of any kind in regions conterminous with the frontier of the other.

The Persian people were dismayed when the terms of this agreement became known to them; Great Britain, which had hitherto shown such sympathy with the constitutionalists, had, it seemed, betrayed them. What was not fully realized in Persia was that this agreement had been forced upon Great Britain and Russia because of their common fear of the growing might of Germany. A subsequent statement by the two powers that the object of the agreement was to prevent intervention and not to bring it about did little to allay Persian disquiet.

A serious crisis occurred in Dec. 1907 when it seemed that the shah was intending to dissolve the *majlis* by force and arrest the leading members. Such strong feeling was aroused that the shah, feigning submission, vowed on the Koran (the most solemn oath in Persia) to preserve the constitution and abide by its provisions. Oaths, however, meant nothing to the shah, who, six months later, ordered his artillery to bombard the *majlis* building, killing and wounding many deputies. Of the survivors a number were seized and executed, but some managed to escape and take sanctuary in the British legation. This outrageous action caused a serious rising in Tabriz which the shah's forces were powerless to quell; it was terminated only when Russian troops, with the ostensible object of protecting their nationals, entered the city in the spring of 1909.

Meanwhile, such was the feeling aroused throughout the country that strong nationalist forces were organized, chiefly at Rasht and Isfahan. In July 1909 these forces combined and marched on the capital, which they entered after meeting with only slight resistance. The shah, fearing for his life, took refuge in the Russian legation. The leading nationalists, the chief *mujtahids* and mullahs and a number of the survivors of the *majlis* then met and decreed the shah's deposition; they chose his eldest son, Ahmad Mirza, who was only 11 years of age, as his successor. Mohammed Ali, who was thereupon exiled, went to Russia. Thus the Persian revolution was accomplished with comparatively little loss of life.

Ahmad Mirza.—The nationalists had won a complete victory, but dissensions soon arose within their ranks and two main parties emerged, the Revolutionaries and the Moderates, between whom great hostility soon developed.

After the nationalist occupation of Teheran and the deposition and exile of Mohammed Ali, Ephraim Khan, the military leader of the Revolutionary party, organized an efficient police administration in Teheran which preserved order there. The Russians, however, on the ground that special measures were needed for the protection of their nationals, dispatched troops to Kazvin whence they refused to withdraw despite protests by Great Britain, which advocated a policy of nonintervention in accordance with the Anglo-Russian agreement of 1907. The lack of administrative experience on the part of the personnel of the new regime soon showed that the governmental departments could not be effectively reorganized without the help of foreign advisers. When this matter was discussed Great Britain and Russia stated that nationals of one or more of the minor powers should be engaged, otherwise they would have to insist on the appointment of their own nationals. These discussions ended early in 1911 when, despite Russian opposition, the Persian government engaged a U.S. citizen, William Morgan Shuster (*q.v.*), to serve as treasurer general of Persia with a staff of four assistants for a period of three years for the supervision, collection and disbursement of the revenues of the country. In June 1911 the *majlis*, by a large majority, passed an act conferring full powers on Shuster in regard to the handling of the national finances; for an assembly which was filled with nationalist sentiment, this was a striking act of statesmanship.

Hardly had Shuster and his staff begun their work when the deposed shah landed on the Caspian coast in order to attempt to recover his throne; his brother, Salar ad-Dauleh, raised the standard of revolt in western Persia, ostensibly on Mohammed Ali's behalf but really, it is believed, on his own. The former shah's forces, which consisted mainly of Turkmens, were defeated, and he was obliged to flee back to Russia; in the west, a force under the capable Ephraim Khan routed Salar ad-Dauleh's supporters.

Although Shuster was given every facility by the Persians, his activities were viewed with disfavour by Russia and in Nov. 1911, though legally in the right, he behaved with some tactlessness toward the Russian consul-general over a case respecting the property of one of the former shah's brothers who claimed to be under Russian protection. Russia thereupon used this matter as a pretext for demanding Shuster's immediate dismissal and threatened to order Russian troops to occupy Teheran in the event of Persia failing to comply. Despite protests by Great Britain, Russia persisted in its attitude, which occasioned strong feeling in Persia. However, faced with Russia's by no means empty threat of armed intervention, the regent, Nasir al-Mulk, by means of a *coup d'état*, dissolved the *majlis* on Dec. 24 and agreed to accede to Russia's demand for the dismissal of Shuster and his colleagues, who thus had to leave the country just when their labours were beginning to produce tangible results. Affairs in Teheran and throughout the country were in great confusion; the financial administration was carried on by Belgian customs officials so far as their limited powers permitted, but any real improvement was naturally impossible in the circumstances.

Russia's policy toward Persia and Great Britain's acquiescence therein, Shuster's dismissal and the consequent failure to organize Persia's finances and to found a new era for the country aroused strong resentment and criticism in the United States and in liberal circles in Great Britain and elsewhere. On the other hand, Sir Edward Grey, the British foreign secretary, and the other members of the cabinet, being deeply concerned at the growing threat of Germany to world peace, were convinced that there was little hope of successful resistance without a *rapprochement* with Russia and that such a vast stake excused a policy of compromise and resulting injustice to Persia.

When World War I broke out in 1914 Persia declared its neutrality, but Turkey's violation of Persian territory in order to attack Russia, and the Turkish threat to the oil field and refinery of the Anglo-Persian Oil company in the south, led to the occupation by British and Russian troops of parts of the country as a countermeasure.

On the conclusion of the war Persia was admitted as an original member of the League of Nations. The defeat of Russia in the war and the subsequent Bolshevik revolution freed Persia for a time from traditional Russian pressure. Great Britain was tempted to take advantage of this changed situation to include Persia in the protective zone that had been established adjacent to India. At the instance of Lord Curzon, then British foreign secretary, an agreement was signed with Persia on Aug. 9, 1919, which, had it been ratified, would have assured British ascendancy in that country. This agreement, while reaffirming the independence and integrity of Persia, provided for the appointment of British military and civil advisers, close co-operation with Great Britain for the construction of railways and other forms of transport and the revision of the customs tariffs. By a second agreement signed on the same day, Great Britain undertook to make Persia a loan of £2,000,000.

On the strength of this agreement, British military and financial advisers were sent to Persia, but their activities were cut short when the *majlis*, in consequence of the strong feeling which the agreement had aroused in the country, refused to ratify it.

The Soviet government, which had already been recognized by Persia, took advantage of this situation to negotiate a treaty in

Feb. 1921 whereby, in order to gain Persia's friendship, it abandoned the imperialistic policy of the tsarist regime by renouncing the use of force and guaranteeing nonintervention in Persian affairs. All the treaties which had been concluded between tsarist Russia and other powers in regard to Persia were denounced, a provision aimed especially at the Anglo-Russian agreement of 1907. Moreover, all concessions which had been granted to the Russian government and Russian nationals were canceled, as were also all loans and debts. All Russian concessionary rights relating to railways, roads, ports and docks reverted to Persia; it was expressly stipulated that none of the property thus returned to Persia could be alienated to any other power. Under article 6, the Soviet government reserved the right to send troops into Persian territory should it become a base for military action against Russia.

In the meantime the weakness and corruption of the cabinet and the incompetence of the young shah had stirred patriotic elements in the country to bring about a drastic change. This change was effected in Feb. 1921 when Sayyid Zia ad-Din Tabatabai, a leading reformer and editor of an influential newspaper, having made contact at Kazvin with Reza Khan, the able and forceful commander of the Persian Cossack brigade, persuaded him to march with his men on Teheran. They entered the capital on Feb. 21, whereupon the cabinet fell. Sayyid Zia ad-Din and Reza Khan then formed a new government, the former becoming prime minister and the latter minister of war and commander in chief. Five days later the treaty with the Soviet government was signed and the Anglo-Persian agreement was denounced.

Three months later, Reza Khan, although still officially only minister of war, gained control of the government, having forced Sayyid Zia ad-Din to resign. He appointed a statesman named Qavam as-Saltaneh prime minister. Almost his first task was the building up of a strong and efficient army; as this object could not be achieved without the funds for providing the troops with regular pay, Reza Khan insisted on certain branches of the ministry of finance being placed under his control as minister of war. By degrees he built up an efficient and disciplined force some 40,000 strong with which he proceeded to establish the authority of the central government throughout the country, particularly in the tribal areas in the southwest which had for long been quasi-independent. The sheikh of Mohammerah (now renamed Khorramshahr) was unwise enough to revolt in 1924, but his forces were defeated and he was compelled to submit; subsequently, he was removed to Teheran where he was detained as a political prisoner until his death in 1934; he had always been on good terms with the British, particularly with the Anglo-Persian Oil company, whose refinery at Abadan was built on property leased from him.

In the meantime, as the finances of the country were in confusion, Reza Khan invited a U.S. financial expert, A. C. Millspaugh, to reorganize them. Millspaugh, who was assisted by a number of other Americans, performed his difficult task successfully. Due to his efforts and to the increasing royalties paid by the Anglo-Persian Oil company, the financial stability of the country was restored.

XI. PAHLAVI DYNASTY

Reza Khan, commander of the Persian Cossack brigade and a leader of the revolt, thereupon made himself prime minister and summoned the *majlis*. He subsequently obtained from that body the grant of comprehensive military powers which could be withdrawn only by it; he thus became completely independent of the shah's authority. For some time past the people had become disillusioned respecting the monarchical form of government, due to the character and behaviour of the last three Qajar sovereigns, and there was some support in the country for the creation of a republic, with Reza Khan as president. The religious leaders, however, having noted the action of the Turks in abolishing the caliphate and divesting Islam of some of its traditional character, strongly opposed the idea of a republic. Reza Khan thereupon decided to retain the monarchy, to depose the shah and mount the throne himself. Accordingly, on Oct. 31, 1925, the *majlis*, by a large majority, declared that the rule of the Qajar dynasty was ended and arranged for the convening of a constituent assembly to make the necessary changes in the constitutional laws. This assembly was duly convened and on Dec. 12 it formally vested the crown in Reza Khan, with right of succession to his heirs. On Dec. 15 the new shah took the oath to defend the constitution and on the following day he was publicly proclaimed amid great popular enthusiasm as Reza Shah Pahlavi (*q.v.*). On April 25, 1926, the coronation took place.

The contracts of the members of Millspaugh's financial mission expired in Aug. 1927 and were not renewed. After a short interval, during which the Belgian customs staff carried on the financial administration, a German financial expert, Kurt Lindenblatt, was appointed in April 1928 to succeed Millspaugh, but with greatly reduced powers.

Following the example of Turkey and Afghanistan, in 1927 Reza Shah gave notice to the powers concerned of his intention to denounce all treaties in which extraterritorial rights (capitulations) were conferred on their subjects. The abolition of these rights was formally put into effect on May 28, 1928. In the previous year, by introducing the French judicial system, Reza Shah had challenged the competence of the religious courts in civil matters. He looked upon the majority of the ulema as backward and regarded their influence as detrimental to his policy of westernizing the country.

During 1927–32 the German firm of Junkers provided passenger and mail air services between Teheran and a number of provincial towns, and in Nov. 1928, after lengthy and difficult negotiations, agreement was reached with Imperial Airways for the establishment of bases in Persia for that firm's services to India.

Relations between Persia and the U.S.S.R. during the earlier years of Reza Shah's reign were marred by frequent disputes over commercial matters. In 1926 the Soviet government, in order to enforce compliance with its demands, placed an embargo on all imports of Persian goods, thus causing great hardship to Persian merchants. The Caspian fisheries were also a bone of contention, but this question was settled by the granting of a new concession to the Soviet government which provided, *inter alia*, for the formation of a joint Perso-Russian company to operate the fisheries. With Great Britain, too, Persia's relations were often far from happy. The most serious crisis occurred in consequence of the Persian government's unilateral cancellation of the D'Arcy oil concession which was held by the Anglo-Persian Oil company. The dispute was referred to the League of Nations, but was ultimately settled by direct negotiations which resulted, in May 1933, in the conclusion of a new agreement on satisfactory terms for both parties. Persia's periodic claims to sovereignty over the Bahrain Islands was another cause of friction, as were also the British coaling stations at Basa'idu (Basidu) and Hanjam (Hangam) (these stations were removed in 1935).

In Persia itself Reza Shah, using his well-trained army with much ability and courage, effectively subdued and disarmed the tribesmen of the southwest, a feat which had been far beyond the power of the previous dynasty. More than this, the Bakhtiari and the Kashgais were placed under the rule of military officers while their chiefs were either put in prison or forced to accept subordinate positions. The same policy was pursued with the smaller tribes. As the tribesmen were made to abstain from robbery, security of the roads in their areas was assured. An attempt to suppress nomadism failed, however, because inadequate provision had been made for the tribesmen to maintain their flocks in the areas chosen for their settlement. The power of the ulema, like that of the nomad chiefs, was also curtailed. Persia was really under military rule.

The shah fully realized the importance of communications, and steady progress in road building was made under engineers from the United States. The postal services were greatly improved, and the Junkers company in 1927 inaugurated a regular air service between Teheran, Shiraz, Meshed, Baghdad and Baku. Radio stations were also established and made available for public use. The construction of a railway line from the Caspian sea to the Persian gulf was eagerly desired by the shah, whose enthusiasm infected the whole nation. U.S. engineers surveyed the various routes, and in the autumn of 1927 the shah inaugurated this great

undertaking. The construction work was undertaken by U.S., European and Persian contractors, with Italian and Persian labour, under the supervision of the Consortium Kampsax, a Danish-Swedish consortium which took over the work in 1933.

Reza Shah's industrialization policy was likewise of great importance for the country; textile, cement, sugar beet and other factories were established in various parts of the country. Many of these enterprises soon showed a profit and contributed to economic stability and to a rising standard of living. Education was substantially reformed and improved, and the proportion of literacy steadily rose. The University of Teheran was established in 1935 and its staff included a number of European experts of good standing. Medicine and hygiene showed a marked advance. The judiciary was remodeled on French lines, and civil offices were opened for marriages. The veiling of women was abolished by a sudden and effective decree in 1935. In these reforms the policy of Turkey was very influential; in fact, Reza Shah modeled himself to a large extent on Mustafa Kemal Atatürk.

In 1935 Iran became the official name of the country.

Foreign Relations, 1938–41.—Naturally enough, Iran viewed the onset of World War II with deep anxiety. Having suffered from the invasion of the Turkish, Russian and British armies in World War I, the country was unanimously resolved to keep clear of all entanglements and preserve its neutrality.

At the outset of the struggle, the sympathies of the Iranian people were largely with the Allies, but the shah himself, some of the ruling classes and a number of army officers tended to favour Germany and Italy, partly because of the long-standing distrust of the U.S.S.R. and Great Britain and partly because they were contemptuous of the timidity and confusion in Allied councils which culminated in the Munich agreement. The shah, resolute and forthright in all things and believing in swift, implacable decisions, was impressed by these same qualities in Mussolini and Hitler. German propaganda, moreover, was well organized and well financed, besides being skilful and unscrupulous.

The Soviet government's accommodation with Germany, the indecision and ambiguity of Allied plans and the disastrous defeat of France convinced the shah, his officers and gradually the bulk of his people that the Allies were doomed. Germany meanwhile had laid its plans well for its new *Drang nach Osten*, aiming at penetrating to the Persian gulf and India.

Since 1935 Germany had held third place in Iranian foreign trade, and by 1938 it had begun to make strenuous efforts not only to enlarge this trade but also to play a dominant role in Iran's internal economic development. Despite the memory of unethical procedures in the German part of the construction of the Trans-Iranian railway and even more of the corruption and mismanagement of some of the German officials of the National bank, the Germans were able by propaganda and infiltration to secure a commanding position in Iran. Moreover, many German technicians were employed in the building up of Iranian industry. Within one year Germany tripled its exports of iron, urgently needed in Iran, radio equipment, military supplies, agricultural machinery and other heavy industrial products. German technicians built chemical, glass and hardware factories and provided highly trained specialists at uneconomic rates to maintain technical services. Propaganda films were supplied free of charge and generous contributions were made to charities. After the Allied occupation of Syria and Iraq, Teheran became a centre for German intrigue for the whole of the middle east, and the German embassy, in accordance with Nazi custom, was heavily overstaffed.

The presence in Iran of a large number of German technicians caused apprehension in Great Britain lest they might attempt to damage or destroy the highly important installations of the Anglo-Iranian Oil company (as the Anglo-Persian Oil company had been renamed in 1935) in southwest Iran. In June 1941, following upon the German attack on the U.S.S.R., the Soviet government likewise viewed the presence of these Germans with alarm. It then made representations to the Iranian government, stating that some of these Germans were organizing bands of terrorists in Azerbaijan and were instigating acts of sabotage elsewhere. As the U.S.S.R. was in urgent need of munitions from the western Allies and as Iran was the only practicable land route, the Soviet and British governments jointly requested the Iranian government to allow military supplies to be sent in transit across Iran to the U.S.S.R. The Iranian government refused to accede to this request or to take action regarding the Germans in the country. The Soviet and British governments then sent an ultimatum to the Iranian government demanding compliance with their demands, but this was rejected. Thereupon, on Aug. 25, 1941, British and Soviet troops simultaneously entered the country from the north and south respectively. British forces also entered Iran from the west, occupying Kermanshah and later making contact with the Soviet forces south of Kazvin. Although the Iranian troops in the south offered some resistance, this was soon brushed aside and the safety of the Abadan refinery and the oil fields was assured. The British and Soviet governments carefully defined their respective zones, the former assuming responsibility for the south, centre and west while the latter occupied the northern provinces of Azerbaijan, Gilan and Mazanderan. The U.S.S.R. could plead justification for its action by citing the Soviet-Persian treaty of 1921 which gave it the right to send troops to Persia should that country become a base for aggression against the Soviet Union.

The immediate consequence of this joint action by Great Britain and the U.S.S.R. was the abdication of Reza Shah on Sept. 16, 1941, in favour of his eldest son, Mohammed Reza Pahlavi (*q.v.*), who was then aged 22. The former shah was exiled first to Mauritius and later to South Africa, where he died in July 1944.

There can be no doubt that Reza Shah, in the earlier years of his reign, had conferred great benefits on his country. He had re-established security and the authority of the central government throughout Persia, he had galvanized the governmental machinery into action, he had done much to promote industry and to improve communications (his greatest achievement was the construction of the Trans-Iranian railway without recourse to a foreign loan) and he had provided facilities for the education and welfare of his people. On the other hand, in his later years he had become increasingly autocratic and arbitrary, with the result that his popularity had waned.

Mohammed Reza Pahlavi.—The new shah, who had been educated in Europe, at once announced his intention of ruling the country on constitutional lines. However, the transition from the arbitrary rule of his predecessor to that of a democracy inevitably proved to be difficult, and there was a great deal of political rivalry and maneuvering in Teheran.

On Jan. 29, 1942, Great Britain, the U.S.S.R. and Iran concluded a treaty of alliance, whereby the first two powers undertook to respect Iran's territorial integrity and sovereignty and to evacuate their forces within six months of the conclusion of hostilities with Germany and its allies. In Sept. 1943 Iran declared war on Germany.

The Trans-Iranian railway proved to be a very great benefit to the Allies, who greatly increased its usefulness, efficiency and capacity by constructing docks and supply centres in the south, connecting the port of Khorramshahr with the Trans-Iranian railway by means of a branch line from Ahvaz and importing many locomotives and additional rolling stock. Great improvements were also made in the road system. The result was a great increase in the quantities of urgently needed war material which the western Allies were sending to the U.S.S.R. across Iran. Also of great value to the Allied cause were the operations of the Anglo-Iranian Oil company in southwest Iran, as they made available large supplies of gasoline, fuel oil and other products.

Although it was not technically an occupation, the presence of British and Soviet troops in Iran was most distressing to the inhabitants, who saw in it a physical renewal of the ancient threat of Russia and Great Britain to partition the country between them. The combination of a bad harvest with the diversion of transport facilities for Allied military purposes led to a serious food shortage in many parts of the country in the winter of 1942–43. Moreover, the situation was aggravated by the refusal of the Soviet authorities in Azerbaijan to allow grain and rice to be sent from that productive province to relieve shortages in other parts of the country. The heavy expenditure by the Allied powers in Iran led

to greatly increased incomes especially in the middle and working classes, while the cessation of importation resulted in a scarcity of consumer goods. The combination of these factors occasioned very severe inflation which threatened the stability of the currency. The cost of living in Teheran and elsewhere soared to ten times the prewar level.

At this juncture the shah and Husain 'Ala, his minister of court, as well as veteran liberals such as Furughi and Taqizadeh who had done so much to create the modern Iran, appealed to the United States for aid; the Iranian people, fearing both Great Britain and the U.S.S.R., felt that the United States had no political ax to grind and recalled that it had in the past rendered friendly and disinterested services. On the recommendation of the state department, A. C. Millspaugh, who had done so much to reorganize the Persian finances during 1923–28, was appointed treasurer general with wide powers, while Col. Norman Schwartzkopf was placed in command of the gendarmery. A U.S. military mission was sent to advise on the administration of the army. U.S. experts were also appointed to serve in the departments of agriculture, health, municipal police, etc.

On Dec. 1, 1943, during the conference of Allied war leaders in Teheran, Franklin D. Roosevelt, Winston Churchill and Joseph Stalin issued a communiqué, at Roosevelt's suggestion, acknowledging Iran's services in the transportation of supplies to the U.S.S.R., promising economic aid during and after the war and reiterating the desire of the three powers for "the maintenance of the independence, sovereignty and territorial integrity of Iran."

Notwithstanding this declaration, the U.S.S.R. continued to extend its influence in the north, supporting the then newly formed Tudeh party and fostering the separatist tendencies of a small minority element in Azerbaijan. In Sept. 1944 the Soviet government suddenly demanded an exclusive oil concession covering the northern provinces and exerted such pressure that the prime minister, Mohammed Sa'id Maraghei, was forced to resign. This brusque behaviour produced a very strong reaction in Iran, and the *majlis* passed a bill which had been tabled by Mohammed Mossadegh (*q.v.*), at that time a comparatively unknown deputy, forbidding the granting of oil concessions to any foreign interests during the war.

Postwar Developments.—When the war was over Great Britain and the United States withdrew their forces from Iran within the period stipulated in the 1942 treaty although the United States had not been a party to it. The U.S.S.R., on the other hand, disregarded its obligations and refused to evacuate the northern provinces. When the Soviet army finally withdrew, it left a number of agents behind who, late in 1945, started a movement designed to make Azerbaijan secede from Iran and join the U.S.S.R. A puppet "democratic" regime was set up in the province, and carefully manipulated elections were held. In Dec. 1946, despite Soviet protests and threats, Qavam as-Saltaneh, the Iranian prime minister, sent a force into Azerbaijan which easily overthrew this regime and re-established Iranian authority. Earlier in that year Qavam as-Saltaneh, during a visit to Moscow, had been forced to sign an agreement with the Soviet government for the establishment of a joint Iranian-Soviet oil company to exploit oil in northern Iran. This agreement proved so unpopular in Iran that in Oct. 1947 the *majlis* declared it null and void.

In 1948 the Anglo-Iranian Oil company offered the Iranian government an increased payment to compensate it for the reduced royalties resulting from the dividend limitation policy of the British government. The Iranian government replied that, while it appreciated this offer, it would prefer to make it form part of a settlement of a more general nature. Negotiations between the government and the company resulted in the signature of a supplemental agreement in July 1949. This agreement, which was to come into force on its ratification by the *majlis*, increased the basic royalty rate and included other substantial financial advantages for Iran.

Later in 1949 the *majlis* passed an act implementing a seven-year plan, an ambitious project for the economic development of the country, to be financed largely by means of the royalties of the oil company. Unfortunately, the plan soon became moribund through the diversion into other channels of much of the money allocated to it, mismanagement and, finally, the cessation of royalty payments in 1951 because of the Anglo-Iranian oil dispute.

Because of the opposition by Mossadegh and his followers, the bill for the ratification of the supplemental oil agreement was withdrawn from the *majlis* in Dec. 1950. When in Feb. 1951 the oil company offered to conclude a 50–50 profit-sharing agreement, the campaign for the nationalization of the Iranian oil industry was already in full swing; this campaign coincided with a wave of intense nationalism. Gen. Ali Razmara, the prime minister, on being asked whether nationalization of the oil industry was practicable, consulted his experts, who reported against it. On March 7, four days after he had submitted their reports to the *majlis*, he was assassinated by a member of an extremist organization.

Mossadegh became prime minister on April 30. On May 1 the act for the nationalization of the oil industry, having passed through parliament, received the shah's assent. Protests by the company and the British government were unheeded and no compromise could be reached. The company, after stopping all oil exports and closing the oil fields and Abadan refinery, was forced to withdraw its British staff from Iran in Oct. 1951. A subsequent offer by the U.S. president, Harry S. Truman, and the British prime minister, Winston Churchill, to resolve the deadlock was rejected in Aug. 1952, and in the following October the Iranian government broke off diplomatic relations with Great Britain.

By the spring of 1953 Mossadegh had lost the support of practically all those groups and individuals who had originally formed his National Front. The explanation of this development is to be found in Mossadegh's complete inability to compromise, his ever-increasing megalomania and consequent clashes with the shah, his insistence on retaining absolute power in defiance of the constitution and his acceptance of support from the Communist-led Tudeh party. He had failed to reap for his country any benefit from his victory over the British, and he had taken no steps to provide Iran with a constructive policy which would enable it to recover from the economic and financial morass into which his actions had precipitated it.

From April 1953 onward there was an open and often violent struggle for power between Mossadegh and Gen. Fazlollah Zahedi, who had been minister of the interior in previous cabinets; as time went on Zahedi's strength increased while that of his opponent waned. After some hesitation, the shah issued a decree appointing Zahedi prime minister in place of Mossadegh, but an attempt to arrest the latter on Aug. 15 failed. So grave did the situation seem that the shah fled by air to Rome, while Zahedi went into hiding. Four days later, however, mob action supported by the army resulted in Mossadegh's overthrow and arrest and his replacement by Zahedi as prime minister. On Aug. 22 the shah returned to Teheran where he received a frenzied welcome. The coup was plainly welcomed by the western powers and was sharply criticized by the U.S.S.R. The United States answered Zahedi's appeal for funds by a first installment of $45,000,000.

On Dec. 5, 1953, Iran resumed diplomatic relations with Great Britain. On Dec. 2, charges of high treason having been brought against Mossadegh, he was sentenced to three years' solitary confinement.

Internally, conditions remained unsettled. In April 1955 Husain 'Ala replaced Zahedi as prime minister. In April 1957 Husain 'Ala was succeeded by Manuchehr Eghbal, the chancellor of the University of Teheran and a personal friend of the shah. Eghbal issued a decree ending martial law, which had been in force for 16 years; he declared his intention of encouraging a free press and free speech, of setting up a democratic two-party system and of allowing the formation of new political parties (except by the Communists).

Meanwhile, with the fall of Mossadegh, the main obstacle to a solution of the oil dispute was removed. Late in 1953 a group of U.S., Dutch and British oil companies formed an international consortium in which the Anglo-Iranian Oil company had a 40% share. In April 1954 the consortium opened negotiations with the Iranian government and the National Iranian Oil company (which had been formed to take over the assets and installations of the Anglo-

Iranian Oil company in Iran). The negotiations resulted in the conclusion of an agreement on Sept. 19. Despite Communist attempts to prevent it, the agreement was ratified by the *majlis* and received the shah's assent. The principal terms of the agreement were that the consortium was to resume operations through two operating companies and that Iran should receive 50% of all the profits on all Iranian oil exported; the Anglo-Iranian Oil company (later renamed the British Petroleum company) was to receive £25,000,000 in compensation over a period of ten years from 1957 and the agreement was to remain in force for 25 years; at the option of the consortium it could be renewed under certain conditions for three periods of five years each.

This important development initiated a policy of increasing economic and political co-operation between Iran and the countries outside the Soviet bloc. In Dec. 1954 Iran signed a commercial treaty with India and also made contracts with British, French, West German, U.S., Dutch and Belgian firms. In Aug. 1955 the Iranian government signed a treaty with the United States and in the following October, despite Soviet protests, joined the Baghdad pact (*q.v.*). Nevertheless, Iran's relations with the U.S.S.R. remained cordial; after lengthy negotiations the two countries concluded a satisfactory agreement whereby the U.S.S.R. agreed to pay its war debt to Iran and to allow the Iranian-Soviet frontier to be mapped.

In the meantime, in March 1956, the shah ordered the implementation of the new seven-year plan, which had already been approved by the *majlis* and senate. In the following year the Iranian government authorized a private U.S. company to undertake in conjunction with the plan organization an ambitious development program in southwest Iran which would include the construction of an immense dam for irrigation purposes and also for the generation of hydroelectric power. Moreover, by the early 1960s good progress had been made with the development of the Iranian oil fields by the consortium, with production exceeding 50,000,000 tons annually. (*See* IRAN: *Economy.*)

In April 1958 the marriage between the shah and Queen Soraya was dissolved, and in Dec. 1959 he married Farah Diba, by whom he had a son, the crown prince Reza, on Oct. 31, 1960, thus assuring the succession in the Pahlavi line.

During 1961–63, under the leadership of the shah, progress was made in the implementation of an important program of political, social, economic and agrarian reform. The most important item in the program was the break-up of the great agricultural estates and the redistribution of the land among the peasantry.

On the night of Sept. 1/2, 1962, in a severe earthquake in northwestern Iran, about 10,000 persons lost their lives.

PERSIAN LANGUAGE. This is one of the modern Iranian languages (*q.v.*). It derives from a southwestern dialect of the Iranian branch of the Indo-European family and is most closely related to Middle and Old Persian, former languages of the province of Fars ("Persia") in southwestern Iran. Modern, or New, Persian is thus called *Farsi* by native speakers.

Persian is the official spoken language of Iran and the only one used for writing; it is the mother tongue of about 10,000,000 people (no exact figures are available) and a means of communication between speakers of mutually unintelligible dialects and languages. It exists in a number of socially, geographically and stylistically definable varieties.

A slightly divergent form of Persian is official in Afghanistan, besides Pashto (*q.v.*). More divergent is Tadzhik, spoken by about 1,000,000 people in the Tadzhik Soviet Socialist Republic and in parts of the Uzbek, Kazakh and Kirgiz Soviet Socialist Republics; Soviet officials classify Tadzhik as a separate language. Persian is written in Arabic characters, Tadzhik in Cyrillic, modified letters being added for special phonological needs.

The segmental phonemes of standard Persian are: i, e, a; *a*, o, u; ey, ow; b, d, g; p, t, k; v, z, q; f, s, x; ž, š; j, č; h, r, l, ?. Syllables never begin with more than one consonant. Word stress is most often on the last syllable.

The vocabulary contains many loanwords, especially from Arabic; in formal style they are sometimes very frequent.

The structure of utterances consists of a combination of word order, intonation, stress and the use of prepositions and affixes. A series of suffixes (*-am, -i, -ast, -im, -id, -and*, corresponding to

the English "(I) am," "(you) are," etc.) marks the predicative construction. To the English verb correspond constructions consisting of some or all of four elements: (1) the prefixes *mi-* or *bi-*; (2) a certain class of morphemes; (3) one or two special suffixes (*-id, -e*); (4) the members of the above series of suffixes. A small group of verbs of general meaning have special forms that function much as do such English nouns as "class" or "concept." Nouns and verbs may be modified (*e.g.*, made more concrete in meaning) by speech situation, context and affixes. Nouns, being uninflected and otherwise lacking in morphological indicators, have to be construed by context. At best, subject and object differ in not being equally tightly bound into the sentence structure.

PERSIAN LITERATURE, the term used to describe literature written in Modern Persian, the form of the Persian language which had emerged by the 9th century A.D. (*see* IRANIAN LANGUAGES). After the Arab conquest of Iran in the 7th century, Islam replaced orthodox Zoroastrianism, and its related heterodoxies, as the dominant religion, and also eclipsed the minority religions, Buddhism, Nestorian Christianity and Manichaeism (all of which had some discernible influence on later literary subject matter and imagery); and Arabic became the language of law and culture. In the 9th century, however, the Persian political revival was accompanied by the emergence of a Persian literary medium, especially in northeast Iran, where the dialect known as "New" or "Modern Persian" began to be used for literary expression and so became established as the literary form of the Persian language in Iran and in northern India (*see* INDIAN LITERATURE: *Muslim Influence*). It also had some influence on Ottoman Turkish literary culture (*see* TURKISH LITERATURE: *Anatolian or Ottoman*). Mid-20th century research, by study of an indigenous spoken dialect preserved among the Iranian people, and of the learned language of Arabic, with its greater vocabulary, has revealed examples of the early form of this language. The first writings in modern Persian were in verse—the medium of praise and pleasure—and Arabic elements were small. As prose translations from Arabic began to be made, rhetorical refinements based on Arab literary conventions and more Arabic words and literary devices were introduced. An example is *saj'* ("rhymed prose"), an Arabic form for which vocabulary resources in two languages were useful (*see* ARABIC LITERATURE: *Belles-Lettres*).

POETRY

First Period.—According to a history of Seistan (Sistan) the first Persian verses were made by Abū Wasīf who was asked by Ya'qub the Saffarid (868–878) to translate some complimentary Arabic lines; this incident is typical in that it shows the new Persian rulers asking for literature in a tongue they knew. According to another legend the first Persian poet was 'Abbas of Merv, said to have composed a poem in Persian in honour of Harun al-Rashid's son, al-Ma'mun, in A.D. 809. The Arab geographer Ibn Khurdadhbih (*c.* A.D. 846) cites a Persian verse by Abu Taqi al-'Abbas ibn Tarkhan, and other fragments from *c.* A.D. 800–850 are coming to light.

The Tahirid rulers (820–873) were more concerned with Arabic than Persian but under the Saffarids (868–900) and especially under the Samanids (873–999) the old dialects of the country reasserted themselves in a much modified form. The Samanids, who ruled in the northeast, established a court giving poets a patronage soon imitated by other dynasties—the Buyids (945–1055), the Ziyarids (928–1042) and particularly the Ghaznavids (962–1186). The Buyids reigned in western and southern Iran and Mesopotamia; the Ziyarids in northern and central Iran; and the Ghaznavids in the east and, later, in large tracts of northern India; hence Samanid literary innovations were widely spread. Yet the force of regionalism remained: although Persian poets spoke for all whose language they used, they also displayed regional characteristics in expression, theme and social preoccupations.

The earliest major genres were the panegyric and elegy, both written in the form of the *qasida* (a formal ode), and their first great exponent was Rudaki (*q.v.*) who flourished under the Samanid Nasr II (913–943). Another form soon to develop was the shorter lyric or *ghazal,* used for bacchic odes and later for love poetry. Both the *qasida* and the *ghazal* were monorhymed. The introduction of the rhyming couplet, *mathnavi,* effected the release from the limitations of monorhyme, and led to the composition of epic and long didactic poems. Like the *ruba'i,* or quatrain, the *mathnavi* was a purely Persian development; and the *ruba'i,* unlike most other poetic forms which were borrowed from the Arabs, was unknown in Arabic.

The Epic.—Under the local Persian dynasties, which had practically freed themselves from the yoke of the Arab caliphate, much attention was paid to the Pahlavi writings recounting the ancient glory of pre-Islamic Iran (*see* PAHLAVI LANGUAGE). Nuh II (976–997) ordered his laureate Daqiqi to put into Persian verse the *Khvatay-namak* ("Book of Kings"), and the poet set to work upon this congenial task but had not progressed very far when he died in the prime of life. The great undertaking was carried forward by Firdausi (*q.v.*), who brought it to a triumphant conclusion by 1010. His *Shah-nama,* though spurned at first by the Ghaznavid Mahmud (998–1030), who had overthrown the Samanids, soon won wide popularity as the national epic of Iran; repeatedly copied in fine and exquisitely illustrated manuscripts, it continued to be recited by professional rhapsodes down to modern times. Other poets soon sought to emulate the success of Firdausi; none came anywhere near to equaling his achievement, though numerous epics on heroic and romantic themes have been preserved. His closest rival is Nizami (*q.v.*) who died about 1202; he composed five epic poems on a variety of topics, including the legendary exploits of Alexander the Great (*see* ALEXANDER ROMANCES: *Eastern Versions*), the life of the Sasanian emperor Bahram Gor and the Bedouin romance of Laila and Majnun. Asadi completed in 1066 a heroic epic on the loves and wars of Rustam's ancestor Garshasp. A little earlier Fakhr al-Din As'ad Gurgani wrote his charming *Vis u Ramin,* later put into Georgian, a poem probably based on Parthian legend which strongly resembles the story of Tristan (*q.v.*) and Iseult. In due course the epic was pressed into service as a handmaid of historiography. Thus, Hamd Allah Mustaufi, otherwise famous as a historian and a geographer, having produced a revised edition of the *Shah-nama,* proceeded to compose the *Zafar-nama,* a gigantic poem reviewing the course of events from the birth of Mohammed down to the year 1331. The exploits of Timur (Tamerlane), and later of the Safavids, were duly made into epics, while it is interesting to mention one of the last ambitious projects of this genre—the *Jarj-nama* composed in honour of George III by a Persian living in India, telling the political history of that country from its discovery by the Portuguese down to the British conquest of Poona in 1817. The Koranic story of Joseph and Potiphar's wife inspired a succession of poets: the first of the series is even attributed to Firdausi's old age, but the ascription has been contested by modern scholars, while the finest treatment was that of Jami (*q.v.*), who gave a mystical interpretation to the tale.

Panegyric.—Panegyric, which forms an important branch of all eastern literatures, is less interesting to the average western reader, but Persian *qasidas* merit the attention of all students of Persian for the mastery of language and expression displayed by the best-known practitioners. This important genre, already perfected in Arabic, especially by al-Mutanabbi (*q.v.*), could be as lucrative to the poet as it was pleasing to his patron; the richer and more powerful the prince, the more numerous his train of encomiasts. Sultan Mahmud of Ghazni created the congenial atmosphere for Farrukhi, Minuchihri, Asadi and 'Unsuri to display their virtuosity; their skilful productions paved the way for the court poets of the Seljuk Sultan Sanjar (1118–57)—Mu'izzi, the "prince of poets"; Adib Sabir; and, most highly esteemed of all

qasida writers. Anvari (*q.v.*), whose elegy describing the sufferings of his countrymen while Sanjar was held captive by invading Ghuzz tribesmen has been brilliantly translated into English as "The Tears of Khorassan," first by William Kirkpatrick (in *Asiatic Miscellany*, vol. 1, 1785), and later by E. H. Palmer (in *The Song of the Reed*, 1877). Contemporary with Anvari was his greatest rival Khaqani (*q.v.*), court poet to the Shirvanshah of northwestern Persia. Khaqani, being erudite in most branches of Islamic learning and a supreme master of Persian lexicography, composed in a forbiddingly obscure style and thus endeared himself to the later crop of commentators. Indeed it was held to be far from a fault in the panegyrist to write obscurely; rather it highly flattered his patron to be supposed capable of understanding the learned references of his poet. Every succeeding dynasty attracted and rewarded its circle of panegyrists, and all the Mogul emperors of India liked to have their exploits celebrated in Persian verse. Nor has the panegyric by any means vanished, though its themes tend to be national and party-political rather than personal. In general, though the lengthy passages of servile flattery make tedious reading in the countless products of the classical age, many *qasidas* contain vivid and beautiful descriptions of natural scenery and great occasions which more than atone for the stretches of boring bombast.

Didactic and Mystical Poetry.—The origins of didactic poetry, ever popular in a country abounding in proverbs, saws and maxims, may be traced back to Firdausi and his times. Abu Shakur of Balkh, favourite of the Samanid Nuh I (943–954), wrote a didactic poem called *Afarin-nama* of which only fragments have survived, but these are sufficient to establish it as the parent of such famous works as the *Bustan* of Sa'di; while Firdausi's *Shah-nama* abounds in sententious wisdom pithily expressed. Religious and mystical poetry was a natural outgrowth of moralizing didactic; the Isma'ili Nasir-i Khusrau (*q.v.*) composed an abundance of ethical and religious poems, while the mystics Abu Sa'id ibn Abi 'l-Khair (d. 1049) and 'Abd Allah Ansari (d. 1089) employed the quatrain to express mystical ideas. The first great mystical epic, the *Hadiqat al-haqiqa*, was composed in 1130 by Sana'i (*q.v.*), of Ghazni, who thus set a fashion which many later poets followed; he wrote a number of shorter epics as well, all of a religious character, and many odes and lyrics containing passages of great mystical insight and beauty. His immediate successor Farid ud-din 'Attar (*q.v.*) wrote numerous epics on religious and mystical themes, the most famous being the *Mantiq ut-tair* which Edward Fitzgerald (*q.v.*) abridged as the *Bird-Parliament*. It was later translated in full in French by J. H. Garcin de Tassy (*Mantic Uttair: le langage des oiseaux*, 1863), and this edition was rendered into an abridged English version by G. C. Nott (*Conference of Birds*, 1955). Mention may also be made of 'Attar's *Ilahi-nama* and *Asrar-nama*, in which mystical teaching is illustrated by lively and well-told anecdotes. He also composed many odes and quatrains, and in prose an extensive and valuable book of memories of the saints. After Sana'i and 'Attar came Jalal-ud-din Rumi (*q.v.*), who died in 1273 having passed most of his life in Konya (Iconium), Asia Minor; his *Mathnawi i ma'nawi*, which draws upon his predecessors, is by far the greatest work of its kind, while in his lyrics and quatrains he reached astonishing heights of pure poetry entitling him to be ranked with the world's great mystical poets. His contemporary Sa'di (*q.v.*), who has always been the most popular moralizing poet of Persia (though in his lyrics he displays a higher poetic gift), lives by his *Bustan* and *Gulistan*—the latter a graceful miscellany of rhymed prose interspersed with passages in verse. Jami's *Baharistan* and Qa'ani's *Parishan* are among the books written in emulation of the *Gulistan*, which has been translated into many languages.

Lyric Poetry.—While the *ghazal* played a minor part in Arabic literature because of the greater popularity of the *qasida*, Persian poets from Rudaki onward showed increasing fondness for the shorter poem. By Sana'i's time the convention of the *takhallus* (the poet's pen name signed in the poem) had been established and remained thereafter the distinguishing mark of the lyric. Whereas the *qasida* sometimes ran to as many as 100 or more couplets in monorhyme, the *ghazal* seldom exceeded twelve and settled down to an average of seven. The *takhallus* generally occurs in the last or penultimate couplet, a convention perhaps encouraged by copyists to distinguish one poet's work from another. The *ghazal* was perfected by Hafiz (*q.v.*) in the 14th century; it has been practised thereafter by almost all the Persian poets including those of India and continues to be popular in modern times.

End of the Classical Period.—Contemporary with Hafiz were 'Ubaid i Zakani (d. 1370), the most talented satirist of Persia; Ibn Yamin (d. 1368), admired for his occasional verse; Khvaju of Kerman (d. 1352), who composed romantic *mathnavis* in emulation of Nizami; and Salman i Savaji (d. 1378), panegyrist to the Jala'irid rulers of Baghdad. The golden age of Persian poetry came to an end with the Timurids, and Jami (*q.v.*; 1414–92) is generally regarded as the last of the classics; he distinguished himself in all branches and was also a notable prose writer. The Safavids, who gave a powerful impulse to painting and architecture, found poetry in a slow decline, though every generation brought its crop of imitators; the outstanding authors are Sa'ib of Tabriz (d. 1677), laureate to 'Abbas II, and, in the 18th century, Hatif of Isfahan (d. *c.* 1784). Under the Qajar dynasty (19th century) lived Qa'ani of Shiraz (d. 1853), considered by some the most brilliant and melodious of all the poets of Persia, though rather indifferent in his choice of subjects.

Persian Poetry in India.—The extension of Muslim rule in India gave rise to an Indian school of Persian poetry, founded by Amir Khusrau (*q.v.*; d. 1325) who lived at the court of the Khilji kings of Delhi and composed brilliantly and extensively in all genres. Thereafter all the Mogul emperors had their laureates, such as Faidi (d. 1590), 'Urfi (d. 1590), Nau'i (d. 1610) and many others. These poets refined and complicated the familiar conceits to such a point that "Indian poetry" became synonymous with obscurity and artificiality.

PROSE

The foundations of Persian prose, as of poetry, were laid in the time of the Samanid dynasty. In 963 Bal'ami, vizier of al-Mansur I, published an abridged translation of the famous annals of al-Tabari (*q.v.*). About the same time a band of theologians from Transoxiana made a Persian version of al-Tabari's other great work, his commentary on the Koran, thus proving that Persian was a fit medium for sacred as well as profane writing. Mansur I also commissioned the first Persian book on medicine, the pharmacopoeia of Abu Mansur Muvaffaq of Herat. The application of Persian to philosophy and science, which involved the coining of an extensive and subtle technical vocabulary, ranks among the outstanding achievements of Abu 'Ali ibn Sina or Avicenna (*q.v.*) whose formative years were passed at the Samanid court.

The Two Styles.—The two translations of al-Tabari mentioned above set a norm of simple and pure Persian style which has seldom been surpassed. The more artificial type of prose, under the influence of the *saj'* of the Arabs, was introduced by Hamid al-Din of Balkh whose *Maqamat*, composed in 1156 in imitation of the *Maqamat* of al-Hariri, proved that Persian was fully equal to all the complications of scholastic Arabic. The "battle of the styles" continued to be fought down the succeeding centuries; the taste of the Mongol conquerors encouraged involved and bombastic prose, satiation with which caused a reaction toward archaic simplicity. This polarity has continued to characterize prose writing ever since.

History.—Of all branches of prose writing, history has always been the most popular and every dynasty of kings and princes has had its circle of professional chroniclers. The anonymous history of Seistan, composed in the middle of the 11th century, was quickly followed by the history of the Ghaznavids by Baihaqi (d. 1077) in 30 volumes (only a sixth has survived). The Seljuk dynasty found a notable historiographer in Ravandi whose *Rahat al-sudur* was written *c.* 1203. The famous vizier Nizam al-Mulk (d. 1092) left a political testament called *Siyasat-nama*, important as a historical source and translated by H. Darke as *The Book of Government* (1960). As advice to rulers it belongs to the same tradition, going back to Sasanian days, as the *Qabus-nama* ("Mirror

of Princes") composed in 1082 by Prince Kai-Ka'us of the Ziyarid house. The advent of the Mongols ushered in an age of historiography. The *Tarikh i Jahan-gusha*, by 'Ala ud-Din 'Ata Malik Juvaini (*q.v.*), was completed in 1260, and is a masterpiece of great historical value. It was translated by J. A. Boyle as *History of the World Conquerer* (1958). Juzjani was another witness of the Mongol invasion, and his *Tabaqat i Nasiri* is especially interesting for its account of the events which occurred in Afghanistan and India. The history of Vassaf, completed in 1312, continues the authentic record of this critical period, but its usefulness is somewhat marred by its inflated style. Along with regional and dynastic histories, Persia has produced a number of universal histories on the grand scale, and the most valuable of these was written during the Mongol period: the *Jami' al-tawarikh* of Rashid al-Din Fadlullah (*q.v.*), who drew upon Chinese and European as well as Islamic sources. The output of histories large and small continued undiminished through the ensuing centuries, and mention may be made here only of a few outstanding works. The career of Timur i Lang and the exploits of his successors in the 15th century are told by Sharaf al-Din 'Ali Yazdi and 'Abd al-Razzaq Samarqandi. Mirkhwand (Mirkhond; *q.v.*), who died in 1498, laboured for many years upon his elephantine history of the world, the *Raudat al-safa'*, much used by early European historians of Islam. Khwandamir (Khondamir), his grandson, abridged this massive work and also compiled the *Habib al-siyar* tracing the emergence of the Safavid dynasty. The life and times of 'Abbas (*q.v.*) the Great were described by Iskandar Munshi, and later Nadir Shah, Karim Khan Zand and the Qajars had their own chroniclers. Many local and provincial histories of great value also exist; while Muslim India yielded a rich crop of general and special works, most of which were described and partly translated in Sir H. M. Elliot's *History of India*, eight volumes (1867–78).

This extensive historical literature is supplemented by many biographical works, particularly of poets, such as the *Lubab al-albab* of Muhammad 'Aufi (d. 1232) who also compiled a valuable encyclopaedia of stories; the *Tadhkirat al-shu'ara'* of Daulatshah, completed in 1487; and the *Atash-kada* of Lutf 'Ali Beg (d. 1781). Nur Allah Shushtari (executed in 1610) composed an important biographical dictionary of mystics and Shi'ite martyrs, and Jami's *Nafahat al-uns* contains valuable notices of the leading Sufis down to his times.

Geography.—Many of the Arabic-writing geographers of the 9th and 10th centuries were Persian, and the oldest geography in the Persian language is the anonymous *Hudud al-'alam*, written toward the close of the 10th century. Nasir-i Khusrau (*q.v.*), famous also as a poet and theologian, left a curious travelogue (*Safar-nama*) of his journey (1046–52) from Merv across Persia, Mesopotamia and Palestine to Egypt and back to Balkh. Of special importance is the geography of the Mongol period which forms a part of the *Nuzhat al-qulub*, a cosmographical work completed in 1430 by Hamd Allah Mustaufi who also compiled an important history, the *Tarikh i guzida*. Toward 1420 Hafiz i Abru finished and dedicated to Shahrukh his untitled geography in which certain Persian provinces are described along with an epitome of their histories. Many valuable additions to Mustaufi are found in Amin Ahmad Razi's *Haft iqlim* (completed in 1594), an encyclopaedia of geography and biography. In the 19th century the impact of western knowledge stimulated the writing of new geographies, and the diaries of the shah Nasir ad-Din (*q.v.*) recording his visits abroad are both entertaining and informative.

Theology and Mysticism.—Arabic was in general preferred by Persians writing on theology, but many important books were also composed in Persian. Nasir-i Khusrau wrote extensively on Isma'ili ideas, as did Nasir al-Din Tusi (1201–1274) during his Isma'ili period; he is best known in Persia for his ethical manual *Akhlaq i Nasiri*. The first Persian handbook of Sufism was composed toward 1050 by Hujviri of Ghazni; 'Abd Allah Ansari of Herat wrote down his *Munajat* or private litanies in charming rhymed prose interspersed with poetry. Mohammed al-Ghazzali (*see* GHAZZALI, AL-; ARABIC PHILOSOPHY) whose main output in the fields of jurisprudence, theology and mysticism was in Arabic, enriched Persian literature with his *Kimiya i sa'adat* on the mystical life and doctrine. His brother Ahmad Ghazzali (d. 1126) wrote a beautiful essay on the theme of the Lover and the Beloved, and Suhravardi Maqtul (executed in 1191) composed a series of mystical allegories in Persian in addition to his many Arabic books. These are but a few titles out of a very extensive literature, including in the 19th century, the writings of the Babis and Baha'is (*see* BABISM; BAHA'I FAITH).

THE MODERN PERIOD

In the 19th and the first half of the 20th century western thought and the demand for social and constitutional reform had their effect on Persian literature. The first signs of a new spirit may be traced back as far as Qa'im-Maqam Farahani (d. 1835), a vigorous stylist in prose and verse, and Amir Kabir (d. 1852). The idea of the novel as an instrument of social criticism sprang from *Hajji Baba* (1824) by James Justinian Morier (*q.v.*), which when first translated into Persian (probably by Mirza Habib of Ispahan, 1905) passed muster for some time as an original composition. It was under the influence of this work that Zain al-'Abidin (d. 1910) wrote his searing *Siyahat-namah i Ibrahim Beg*. Translations of foreign romances, such as the works of Alexandre Dumas, Jules Verne and the Arab Syro-Egyptian historical novelist Jurji Zaidan, stimulated the growth of the historical novel celebrating the splendour of ancient and medieval Iran; mention may be made of the *Dastan i Shams u Tughra* of Mohammed Baqir Khusravi (1909), the *Ishq u sultanat* of Musa Nathri (1919) and the *Damgustaran* of San 'ati-zada (1920–25). The first successful experiment with the short story was made by Jamalzada in his *Yaki bud yaki nabud* (published in Berlin, 1922); his lead was followed by many writers, of whom the most noted are Mohammed Hijazi (b. 1900, who also composed plays, essays and novels), Buzurg 'Alavi (b. 1908), Sadiq Chubak, Jalal Al i Ahmad and above all Sadiq Hidayat (d. 1951). The last-named author, who was a learned antiquarian and folklorist, came into great prominence as the inventor of the "new style" which brought into literature many words and idioms previously current only in colloquial speech. His most famous novel *Buf i kur* attracted wide interest and was translated into English and French (*The Blind Owl*, trans. by D. P. Costello, 1958; *La Chouette aveugle*, trans. by R. Lescot, 1953). The followers of this fashion were generally liberal in politics, and controversial.

The work of the first modernist poets, such as Adib i Pishavari (d. 1930), Adib al-Mamalik (d. 1917) and Iraj-Mirza (d. 1926), although important, was overshadowed by that of later writers. The earliest revolutionary poet was 'Ishqi, murdered in 1924; another was Lahuti (d. 1957), who spent the latter half of his life in the U.S.S.R. The most eminent of the "conservative" poets were Malik al-Shu'ara, mentioned above, and the remarkable woman writer Parvin i I'tisami (d. 1941). Though Sir Mohammed Iqbal (*q.v.*; d. 1938) was an Indian, his Persian poetry has been accepted into the canon of the national literature. Many poets rose to prominence after World War II, among them Parviz Natel Khanlari (1914–), editor of the literary magazine *Sukhan*, Mohammed Hussein Shahriyar (1904–), Gulchin, Fereydun Tavallali and Yasimi. Their work exhibited the increasing influence of western contemporary styles.

The extent of the modern renaissance of Persian letters is strikingly shown by the remarkable advance in book production. Not only were the Persian classics being edited in a scholarly manner—and much credit for this belongs to Mirza Mohammed of Qazvin—but a constant flow of original writings came from the presses in elegant and attractive print. The output was all the more astonishing since the reading public was still severely restricted by the low literacy figures, which, however, progressively rose as new schools and colleges were built.

The Press.—An important part in the modern literary movement has been played by the press, which has provided a forum for political and sociological discussion, for new literary criticism and for poetry on political and other new themes. The first Persian newspaper in Teheran appeared in the reign of Fath 'Ali Shah (1797–1835). Certain organs founded abroad by exiles or expatriates exercised real political influence during the long years of

struggle for a modern constitution; Istanbul, Calcutta, Cairo, Paris, London and Berlin all contributed at various times and in various ways. After the revolution of 1905–08 newspapers proliferated in Persia itself, and the number of titles runs into hundreds; the competition of wireless did not sensibly diminish the flow.

From the purely literary standpoint, the press rendered the language more pliant, simple and popular. Daily papers revealed the talents of 'Ali Akbar Dahkhuda (d. 1956), good poet and excellent reporter imitating in his satires the humorous speech of the bazaars; the poet laureate Malik al-Shu'ara' Bahar (d. 1951); and many others. Magazines, especially those devoted to literature and social comment, were also produced in great numbers, some fugitive and some more firmly established; through this medium many essayists and writers of short stories first appeared before the public. The Persian press had by the mid-20th century become as competent and influential as that of any comparable country.

BIBLIOGRAPHY.—The most complete survey of Persian literature is E. G. Browne, *A Literary History of Persia*, 4 vol., 2nd ed. (1929). Other comprehensive surveys are C. A. Storey, *Persian Literature: a Bio-bibliographical Survey*, vol. i, pt. 1 (1927–39), vol. i, pt. ii (1954); Zabihollah Safa, *Tarikh i adabiyat dar Iran*, 2 vol. (1956–57). The Persian literature of India is fully described by Muhammad Abdu'l Ghani in *A History of Persian Language and Literature at the Mughal Court*, 3 vol. (1929–30) and *Pre-Mughal Persian in Hindustan* (1941). An extensive account of Persian poetry is Shibli Nu'mani, *Shi'r al-Ajam*, 5 vol. (1907–24), and the development of Persian prose style is traced by Muhammad Taqi Bahar in *Sabk-shinasi*, 3 vol. (1940–44). Shorter works include I. Pizzi, *Manuale di Letteratura persiana* (1887) and *Storia della poesia persiana*, 2 vol. (1894); P. Horn, *Geschichte der persischen Litteratur* (1901); A. E. Krymski, *Istoriya Persii, yeya literatury i dervisheskoi theosofii*, 3 vol. (1906–17); R. Levy, *Persian Literature* (1923); A. J. Arberry, *Classical Persian Literature* (1958); R. N. Frye, *The Heritage of Persia* (1962).

Among anthologies of Persian literature in translation are H. Massé, *Anthologie persane* (1950); A. J. Arberry (ed.), *Persian Poems* (1954). Most of the foregoing works contain extensive bibliographies which may be consulted for further details on individual schools and authors. *See* also bibliographies to articles on individual authors.

(V. F. M.; A. J. Ay.; P. W. A.)

PERSIMMON, the globular fruit of trees of the genus *Diospyros*, which belongs to the ebony family (Ebenaceae). The oriental persimmon (*D. kaki*) is an important and extensively grown fruit in China and Japan where it is known as *kaki*. It was introduced into France and other Mediterranean countries in the 19th century and grown to a limited extent there. Introduced into the United States a little later, it is grown commercially on a small scale in California. It is grown throughout the Gulf states of the U.S., mainly in home gardens. The fruit is two to three inches or more in diameter, yellow to red in colour, somewhat resembling a tomato in appearance. Except for varieties such as Fuyu, the fruit tends to be highly astringent until soft-ripe or, as is done in Japan, until treatment with certain gases. The trees will tolerate winter temperatures only to about 0° F.

The native American persimmon (*D. virginiana*) is a small tree, occasionally up to 40 ft. in height, and is native from the Gulf states north to central Pennsylvania and central Illinois. The fruit is one to two inches in diameter, usually rather flattened, and dark red to maroon in colour. Most fruits contain several rather large, flattened seeds. As in the Oriental species, the flesh loses its astringency and develops a rich flavour when it becomes soft. Considerable quantities are gathered from the wild and utilized. A number of superior kinds have been named and propagated to a limited extent, but are not grown commercially.

See W. H. Chandler, *Deciduous Orchards*, 3rd ed., pp. 409–415 (1957).

PERSIS, the Greek form of Old Persian *Parsa*, modern Fars (*q.v.*), the southwestern part of Iran. It derived its name from the Iranian tribe of the Parsa (Persians) who settled there in the 7th century B.C. As was observed by Nearchus, the admiral of Alexander the Great (preserved by Arrian, *Indica*, 40 and Strabo, *Geography*, xv, 727), the country is divided into three parts of different character and climate. The seaboard is hot and sandy with little vegetation apart from date palms, the population is sparse, and there are no good harbours. About 50 mi. (80 km.) from the coast rise mountain chains through which steep passes lead to interior valleys, which lie about 5,000 ft. (1,524 m.) above sea level. There the climate is temperate, the country watered by rivers and lakes, the soil fertile and excellent for cattle rearing. It was in this area that there arose the brilliant civilizations of the Achaemenids and Sassanids. The third, northern part belongs to the central plateau and is still higher and colder in winter. Persis was bordered on the east by Carmania (Kerman), on the west by the Persian Gulf and Elam, on the northwest by Media, and on the north and northeast by the great desert.

The exact date and the circumstances of the occupation of Persis by the Persians are uncertain. It is possible that they derived their name from residence in the land Parsuash, south of Lake Urmia (Rezaiyeh), which is mentioned in Assyrian records between the 9th and 7th centuries B.C. By the 7th century, however, they had migrated southward to a district on the eastern frontier of Elam known to the Assyrians as Parsumash. Its Persian ruler, Cyrus I, acknowledged Assyrian overlordship following the campaign of Ashurbanipal against Elam (*c.* 640). In the Babylonian records Cyrus II is described as king of Anshan, a district on the Elamite border known since Sumerian times, and as king of Parsu (Parsa). Some scholars maintain that Parsumash, Anshan, and Parsa were separate districts conquered successively by the Persians, perhaps under the leadership of Teispes (*c.* 675–640). Others believe that they were alternative terms for the same area.

The Persians were a vigorous race, living in a healthful climate, accustomed to hardship, brave, and warlike. Herodotus lists their leading tribes as the Pasargadae, to which belonged the clan of the Achaemenidae, the royal family of Persia; the Maraphii; and the Maspii. It was these three that Cyrus II assembled to approve his plans for his revolt against Astyages, his Median overlord, in 553. Lesser tribes were the agricultural Panthialaei, Derusiaei, and Germanii (the Carmanians, living round Kerman, which takes its name from them) and the nomad Dahae, Mardi, Dropici, and Sagartii (Old Persian, Asagarta). Strabo also lists among the Persian tribes the Pateiskhoreis (Old Persian, Patishuvari), to which belonged Gobryas, the lance bearer of Darius I mentioned in the king's tomb inscription.

The inhabitants of Persis were considered to be the rulers of the empire and were exempt from taxation. This privilege was not, however, extended to Persian tribes living outside Persis, for example the Sagartians. As the homeland of the Achaemenid dynasty, Persis was closely associated with the monarchy. Cyrus II built his capital at Pasargadae (*q.v.*) in the territory of his tribe, and about 30 mi. (48 km.) to the southwest Darius I founded his new capital of Parsa, "the Persians," known to the Greeks as Persepolis (*q.v.*), "the Persian city." Although Persepolis was too remote to function as the administrative centre of the empire, which was fixed at Susa in Elam, it served as the spring capital. It was there that the king received homage and tribute of the subject

nations at the New Year festival, a ceremony which forms the subject of the magnificent reliefs of the apadana platform. Large amounts of the gold and silver received as tribute were stored in the treasuries at Pasargadae and Persepolis. Achaemenid kings were crowned at Pasargadae and buried on their native soil, Cyrus II at Pasargadae, Darius I and his immediate successors at Naksh-e Rostam, and later rulers at Persepolis. (J. M. M.-R.)

Post-Achaemenid Period.—When Alexander had won the victory of Gaugamela (Arbela) and occupied Babylon and Susa, he met (in the spring of 330) with strong resistance in Persis, where the satrap Ariobarzanes tried to stop his progress at the "Persian gates," the pass leading up to Persepolis. There Alexander set fire to the cedar roof of the palace of Xerxes as a symbol that the Greek war of revenge against the Persians had come to an end. It is said that he soon had the fire extinguished (Plutarch, *Alexander*, 38); the story of the feast at which Thaïs incited him to the burning is pure fiction, and it may well be that he repented the damage he had done (Arrian, *Anabasis*, vi, 30, 1).

Alexander had planned to amalgamate the former rulers of the world with his Macedonians. Peucestas, the new satrap of Persis, followed the example of Alexander and thus gained a strong hold on his subjects (Diodorus Siculus, xix, 48). About 311 the Iranian satrapies passed to Seleucus I Nicator. The subsequent history of Persis is obscure. There is little literary or archaeological evidence for the foundation of new cities, which was a conspicuous mark of Seleucid policy elsewhere. Laodicea in eastern Persis and Stasis, possibly a garrison town under Antiochus I Soter, are mentioned by Pliny the Elder and Stephanus Byzantinus; on the Persian gulf, Antiochia (Bushire) was founded by Antiochus I to replace an Elamite town and peopled with Greeks including a large contingent from Magnesia on the Maeander (Kuçukmenderes Nehri).

Lying apart from the main strategic and economic highways of Iran, Persis preserved its ancient culture, language, and religion; new sanctuaries at Persepolis and at Nurabad were built on traditional Iranian lines, by contrast with the temples, Greek in plan and style, erected in the same period at Kangavar, Khurha, and Nahavand in Media. Four series of coins, inscribed in Pahlavi, attest the effective independence of local princes in the district of Istakhr (Estakr, the town which succeeded Persepolis), probably as early as the reign of Antiochus I. Their names are Iranian and they are depicted in Iranian dress; the reverse types include the symbol of Ahura Mazda, the traditional Iranian "standard of Kaveh," and fire altars or temples. The four rulers of the first series, assigned to the 3rd century B.C., bear the title *Frataraka* ("governor"). One of them, Vahuberz (Oborzos), is said to have massacred 3,000 Greeks, and the destruction of 3,000 Persian rebels by a general of Seleucus II Callinicus may have been retaliation for this act (Polyaenus, *Strategica*, vii, 39 and 40).

In 220 a rebellion by Molon, satrap of Media, and Alexander, satrap of Persis, was suppressed by Antiochus III, but Persis was probably among the first of the Iranian satrapies to proclaim their independence after Antiochus' final defeat by Rome at Magnesia (winter 190–189). An attempt by Antiochus IV Epiphanes to restore Seleucid authority in Iran met with only transitory success, and soon after his death (163) Persis was forced to acknowledge the supremacy of the Parthian Mithradates I, although some of the inhabitants supported Demetrius II Nicator in his unsuccessful attack on Mithradates in 141.

The three later series of coins, dating between the 2nd century B.C. and the 3rd century A.D., give the rulers of Persis, who are shown in Parthian dress, the title of king. Strabo says that they were vassals of the Parthians and it is stated in the *Periplus of the Erythraean Sea* that their authority extended over the shores of Carmania and the opposite coasts of Arabia. Among them are found the traditional names of the Achaemenid dynasty and of Iranian mythology, Daryav (Darius), Artakhshatr (Artaxerxes), Narses, Manucihr, and others. In the early 3rd century there were different petty kingdoms and usurpers in Persis; the principal dynasty is called Bazrangi by the Arab historian al-Tabari. Sasan, the grandfather of Ardashir I (*q.v.*) and high priest of the temple of Anahita at Istakhr, was connected by marriage with the Bazrangi house, and this connection obtained for Ardashir a military command at Darabgird, which he used to subdue the rest of Persis. Meanwhile his father, Papak (Pabhagh, Babek), son of Sasan, supplanted the Bazrangi king Gochihr. In 208 the crown passed to Ardashir, who then conquered the neighbouring provinces of Carmania and Susiana and in 224 defeated and killed the Parthian monarch Artabanus V. He was crowned "king of kings" at Ctesiphon in 226. The Sassanid dynasty which he founded was thus heir to the Achaemenid cultural tradition and closely connected with the traditional Zoroastrian religion, which was henceforward maintained as the state religion of the empire (*see* ZOROASTRIANISM).

Istakhr, the new capital of Persis, lay about 9 mi. (14 km.) above Persepolis on the Pulvar River (Rudhkhaneh-ye Sivan). It was a great city under the Sassanids and was important in early Islamic times, when it was noted for its fanatical adherence to the old religion. It was destroyed in the mid-11th century. *See* also PERSIAN HISTORY. (E. E. D. M. O.)

PERSIUS (in full, AULES PERSIUS FLACCUS) (A.D. 34–62), Latin poet whose satires, written under the influence of Stoic philosophy, reach a higher moral tone than any other work of their kind in classical Latin literature and are also remarkable for the author's individual use of language. According to the *Life* attached to his poems in the manuscripts, Persius was born at Volaterrae in Etruria (hence his Etruscan name Aules, often latinized as Aulus), of a family of equestrian rank. Having lost his father when he was about six years old and his stepfather a few years later, he went to Rome at the age of 12 to study under Remmius Palaemon and the rhetorician Verginius Flavus. At the age of 16 he began a close friendship with the Stoic philosopher L. Annaeus Cornutus, whose pupil Lucan was also to show himself to be a generous admirer of all that Persius wrote. Another friend from his early youth was the lyric poet Caesius Bassus, and his friendship with Thrasea Paetus (whose wife Arria was a relative of his) lasted for some ten years. Later he met the younger Seneca, but was not attracted by his mind.

His reading of the tenth book of Lucilius revealed to Persius his vocation, and he began to write his own book of satires. He wrote slowly, however, and left his book unfinished at his premature death. Cornutus then suppressed all that Persius had written except the book of satires, in which he made some slight alterations before handing it over to Bassus for editing. On publication, it had an immediate success. Persius is said to have been gentle in disposition, girlishly modest, good-looking and affectionately devoted to his mother, sister and aunt. To his mother and sister he left a considerable fortune.

The six satires, which amount only to 650 lines, are composed in hexameters; but what appears as a prologue, in which the poet ironically asserts that he writes to earn his bread, not because he is inspired, is in choliambics. The first satire, which censures the literary tastes of the day as reflecting the decadence of national morals (this theme is not unlike that of Seneca in *Epistulae morales*, 114), contains a vivid description of a poet reciting his own work, a scathing account of literary conversation at a dinner party and an interesting passage deriding specimens of bland mythological writing and languishing style. Here Persius writes real satire, treating what he himself has seen with understanding, whereas the remaining five satires in his book are in fact philosophical discussions on themes often handled by Seneca. Satire ii discusses what we may justly ask from the gods; satire iii, those who live wrongly though they know the right and those who have not been enlightened by philosophy; satire iv, the necessity of self-knowledge for public men (*cf.* Plato, *Alcibiades I*); satire v, the Stoic doctrine of freedom (introduced by friendly allusions to the teaching of Cornutus); and satire vi, the proper use of money.

In earnestness and moral purpose Persius rises far above the political rancour or good-natured persiflage of the earlier Roman satirists on the one hand and the rhetorical indignation that Juvenal was later to display on the other. He seems, as it were, a forerunner of the great Christian apologists. His thought, however, is often very difficult to follow, and the meaning of his powerful expressions is sometimes far from clear. He seeks

brevity at all costs, and he is clumsy in his management of dialogue, so that it is often hard to know where one speaker is supposed to leave off and another to begin. Frequently his metaphors are strained and his colloquialisms jarring. He takes not only characters but also whole phrases, thoughts and situations from Horace, despite his great difference from Horace in ideals, temperament and technique.

Yet Persius can write with natural simplicity and genuine eloquence (as in ii, 61–75; iii, 23–43; and v, 26–29) and occasionally has passages memorable for their realism or for their metaphor: for instance, *nescit quid perdat et alto Demersus summa rursus non bullit in unda* (iii, 33–34: "he does not know what he is losing and, drowned in the depths, sends not a bubble back to the surface") or *dum veteres avias tibi de pulmone revello* (v, 92: ". . . while I pluck your old grandmother's notions from your breast").

The *Life* states that before the publication of the book of satires some lines were removed from the end so that it should appear to have been completed; this may mean that an unfinished sentence or paragraph had to be omitted. Cornutus is also said to have suppressed an offensive allusion to the emperor Nero's literary taste, changing the original *auriculas asini Mida rex habet* ("King Midas has ass's ears") to *auriculas asini quis non habet?* ("Who has not ass's ears?"; i, 121).

BIBLIOGRAPHY.—Modern editions of the satires: S. G. Owen, 2nd ed. (1908; with Juvenal); O. Jahn, 4th ed.,.rev. by F. Leo (1910; with Juvenal); S. Consoli, 2nd ed. (1911); G. G. Ramsay, with Eng. trans. (1918); and W. V. Clausen (1956). Editions with commentaries include: I. Casaubon (1605; new ed. with additions by F. Dübner, 1833); O. Jahn, with scholia (1843); C. F. Heinrich (1844); B. L. Gildersleeve (1875); J. Conington, rev. by H. Nettleship, with Eng. trans. in prose, 3rd ed. (1893); G. Némethy (1903); J. van Wageningen, with Dutch trans. (1911); F. Villeneuve (1918); and N. Scivoletto (1956). English verse translations: John Dryden (1693); and J. Tate (1930).

(G. B. A. F.)

PERSONALITY. In defining personality the psychologist employs the two indispensable ideas of integration and uniqueness. While the various other concepts and principles of psychology refer to one or another segment of behaviour, personality invariably signifies, for one thing, the functioning of the whole person, and, for another, the unique organization of the individual that distinguishes him from his fellows. In accounting for a personality it therefore becomes essential to know how the person, in expressing his needs and his social relationships, functions as a recognizable unity with distinctive traits, drives, attitudes and habits which enable or prevent his attaining an adequate adjustment to his environment and to himself.

In the early 19th century James Ward in England stressed the individualistic orientation of the psychology of personality; in Germany, Wilhelm Stern adopted a similar standpoint in his personalistic approach. In conventional psychology textbooks personality is placed at the top of the conceptual hierarchy: the lower-order concepts lead systematically to personality as the most complex and inclusive.

There is a point of view, dating from about 1950, according to which personal experience is only one aspect of psychology; other aspects refer to other levels of behaviour. From this standpoint "psychology" would have to be replaced by the collective phrase "behavioural sciences" or, more simply, by the single term "humanics." Thus a reflex action, such as the blink of the eyelid in response to a sudden visual stimulus, would be regarded as behaviour at the physiological or neurological level, whereas a marked like or dislike of some other person, say a brother or sister, would fall directly within the domain of "personality" (more strictly, psychodynamics or idiodynamics; *see* below).

There is no unanimity of thought regarding personality in subhuman organisms, though, on the whole, psychologists tend to reserve the term, with or without sufficient justification, for the human species. Character (*q.v.*), as distinguished from personality, usually involves moral and other normative judgments. It is therefore used only sparingly in U.S. psychology, although in European writing the term often is equated with personality. Values, like any other data, are for the scientist a part of nature. Good and bad (as qualifiers of character, etc.) are always to be designated as belonging to a specific ethical frame of reference, not necessarily that of the observer or his social group.

To find one's way in this area of scientific research one must keep constantly in mind the difference between observation and explanation. In this account the methods of observing personality will first be described, followed by a survey of personality theory.

METHODS OF OBSERVATION

Subjective Methods.—In the subjective methods the subject himself discloses what he knows about himself. He makes himself an object of observation and reports his finding to the psychologist. Among the techniques used here are: the autobiography, elements of the life or case history, some types of interview and the so-called inventory method in which the subject reports about himself on a standardized questionnaire or check list. That these self-reports have the advantage of direct relevance and broad scope—who should know better than the person himself or have access to more facts about him than he does?—is readily appreciated; but these advantages are obviously counterbalanced by conscious or unconscious deception of self and others. It is therefore essential to include in such subjective methods control or stabilizing devices that help to identify at least the more obvious deceptive reports.

Objective Methods.—The objective methods of observation depend not upon the subject's own statements about himself but upon his overt behaviour as revealed to others who serve as examiners, observers or judges. Here are included not only verbal behaviour but physiological responses (blood pressure, heart rate, etc.), which may be recorded by special instruments, and adaptive or expressive physical or social responses (*e.g.,* intelligence tests). Objective observations may be made in the natural state (*e.g.,* the interview) by attending less to what the subject says about himself and more to his nonverbal, adaptive responses such as his stance, the amount rather than the content of his verbalization, nervous manifestations such as fidgeting, etc. Again, miniature life situations may be created in the laboratory for the single individual or for small groups that interact with each other under conditions defined by the investigator. Sometimes such observations are made through one-way observation screens or mirrors, and cinematic records of these observations may be obtained. Microphones may also be used to record verbal responses.

As will be noted, even in such objective methods of observation as those just described the verbal response of the subject may still play an important part. The difference between these records and the self-reports mentioned among the subjective methods lies in the treatment of the obtained data. In the objective approaches the verbal behaviour of the person is not necessarily construed at its face value. Instead it is treated much like any other behaviour; *e.g.,* movements of the limbs or of the internal organs. In such a frame of reference the verbal output of the subject is analyzed quite apart from his own conscious intent to communicate information about himself. The subject has merely behaved in a certain way under the given stimulating conditions. The quantity, form and content of his utterances may then be submitted to measurement and analysis. In the second quarter of the 20th century new techniques for the systematic analysis of verbal behaviour were contributed by a group of specialists devoted to the fields of semantics and information theory. (*See* also SEMANTICS, GENERAL; INFORMATION THEORY.)

Projective Methods.—The projective methods of appraising personality differ from both the subjective and the objective by approaching personality indirectly. Neither the person himself

nor the examiner takes the subject as an object of direct observation; instead the subject is requested to behave in an offhand manner—merely to exercise his imagination, to let himself go without self-criticisms or adaptive intent. In other words, he is encouraged to "project" himself and thus to reveal the implicit or unconscious content of his personality. The earliest of the projective methods employed on a systematic basis was that of word association, introduced by Francis Galton in 1879. Stimulus material is provided by individual words to which the subject responds with the very first word that comes to his mind as he hears the stimulus (*see* also ASSOCIATION, MENTAL). Sigmund Freud modified Galton's word association method into the free association technique for analyzing dreams, etc., as an aid to psychotherapy and personality research. Here the person responds to his own previous responses, *e.g.*, images from his own reported fantasies or dreams. In the inkblot method of Hermann Rorschach the subject is asked to tell what the blots look like to him. Responses provide clues to the subject's usual perceptual approach to real objects in terms of his habits, interests, needs and abilities. Another projective method is the Thematic Apperception Test, in which the subject is invited to tell stories in response to pictures that he is shown. Finally may be mentioned the Rosenzweig Picture-Frustration study. Cartoonlike drawings that portray a series of everyday frustrating social situations serve as the stimuli for the subject, who is asked to supply (in the blank caption box above the head of the frustrated person) the first verbal response that comes to mind. As will readily be seen, all these projective techniques encourage the person to respond in terms of his own bias, with a minimum of external stimulation, since their common aim is to assay that bias. The methods of assessing personality are discussed in detail in PSYCHOLOGICAL TESTS AND MEASUREMENTS: *Tests of Personality and Temperament.*

STRUCTURE OF PERSONALITY

A large class of concepts used for explanation or prediction refers to the structural organization of personality. Concepts of structure help to account for observed consistencies in behaviour at any given time (congruence) or from one time to another (homogeneity).

PERSONALITY TYPES

The concept of personality type makes two assumptions: (1) that personalities are divisible into two or more groups each of which excludes the other and (2) that in each type are to be found certain mutually dependent and interrelated traits or patterns of response that can be inferred from each other. This theory has an obvious appeal because of its simplicity. As a result of experience and experiment, however, the view, while still having its adherents, is rarely entertained in its simple form. Even as abstractions personality types have a very limited usefulness and often contribute more to prejudice and to hasty generalization than to sober judgment or real knowledge.

Humoral Types, Temperament and the Endocrines.—Historically, type theories go back to Galen with his four humors —blood, phlegm, choler (yellow bile) and melancholy (black bile) —from which the four temperaments—sanguine, phlegmatic, choleric and melancholic—were derived. While this humoral psychology was long ago abandoned, the words denoting the four types have been absorbed into occidental language. Moreover, the essential idea that bodily disposition, or perhaps even predisposition, determines difference in temperament still has its exponents. The humours themselves have been replaced by the secretions of the endocrine glands.

Personality is an organismic unity, embracing both physiological and psychological manifestations. Biological maladjustments can lead to serious disturbances in the cognitive and emotional life of the person, and, also, psychological upsets can disturb physiological functioning. Both the autonomic nervous system and the endocrine glands participate in such control. For example, overactivity of the thyroid gland results in nervousness, irritability and insomnia, in addition to the usual physical symptoms. Underactivity of the thyroid will bring about sluggishness, apparent mental deficiency, indifference to emotional stimuli, and so on. Again, the endocrine secretions of the sex glands have much to do with typical masculinity and feminity of personality as well as physique. Boys showing emotional and recreational interests below those typical of their chronological age have increased markedly in maturity upon receiving injections of male hormone. The pituitary, parathyroids and adrenals also affect personality traits (*see* also ENDOCRINE GLANDS). Various studies have attempted to relate phases of blood chemistry, such as acid-base balance, calcium-potassium ratio and sugar tolerance, to personality variables. While some of the experiments have returned encouraging results, none can be said conclusively to have proved a correlation between the physical and the psychological measurements. It must be emphasized that the positive findings with respect to endocrine glands relate mainly to instances in which glandular function was distinctly above or below normal. Interpretations of normal personality trends in terms of endocrine function must in the 1960s be regarded as largely speculative. A similar restriction applies to the data with respect to autonomic nervous system function (*see* also TEMPERAMENT; PSYCHOLOGY, PHYSIOLOGICAL; NEUROPHARMACOLOGY AND PSYCHOPHARMACOLOGY; TRANQUILIZING DRUGS).

Morphological or Physical Types.—A second chief theory of types depends upon the conformation of the human body—of its component parts or tissues. These morphological or physical types are then regarded as giving rise to, or being correlated with, types of personality. This theory is found in general terms in early Greek medical concepts. In the 19th century a notable contribution was made in France by L. Rostan, who distinguished digestive, muscular and cerebral types. About 1885 A. de Giovanni founded his school of clinical anthropology in Padua. His pupil G. Viola, utilizing the earlier work of the German Friedrich W. Beneke, and Viola's pupil S. Naccarati conducted detailed anthropometric studies with specified indexes for measuring the dimensions of physique and relating them to each other. The German psychiatrist, Ernst Kretschmer (*q.v.*) at about the same time was led by his work with mental patients to develop a threefold physical classification: pyknic, asthenic and athletic. The pyknic is characterized by a broad trunk and relatively short limbs, round face, usually with a tendency to gain weight in middle age; the asthenic has a narrow trunk, shoulders and hips, long limbs, long narrow face and is generally lean; the athletic has broad shoulders and trunk, narrower hips, well-proportioned limbs and good muscular development. Kretschmer found a marked predominance of the cyclothymic temperament among pyknics; *i.e.*, they tended toward extremes of gaiety and depression. By contrast the asthenics were introverted, shy, serious and ranging in temperament from hypersensitive to phlegmatic and dull. This latter pattern he called schizothymic. The athletic physique was found to be intermediate in temperament. Kretschmer's views were attacked on the grounds, first, that it is impossible to classify most persons in any of his three physical groupings with any degree of accuracy and, second, that there are too many exceptions to the expected temperamental relationships when physical classification seems fairly definite (*see* also PHYSIOGNOMY).

A considerable improvement on Kretschmer's work appeared in the research of W. H. Sheldon. In his approach the arbitrary classification of individuals into physical types was replaced by three ratings (on a seven-step scale) on three extreme physical patterns: the ectomorphic (resembling Kretschmer's asthenic), the mesomorphic (athletic) and the endomorphic (pyknic). Sheldon next reported three patterns of temperament (cerebrotonic, somatotonic and viscerotonic) and found that the physical and temperamental types agreed in a rather large proportion of cases. While this quantitative development might be expected to appeal to psychologists, Sheldon's conclusions have not been fully confirmed and have been looked upon with some doubt.

Psychological Types.—It was in psychiatry and philosophy that the third chief doctrine of types first emerged. As representative in the 20th century, the views of C. G. Jung and E. Spranger may be cited. Jung coined the terms introversion and extraversion to describe what he considered to be contrasting types.

Introversion was characterized as directing attention and interest inward, with a tendency to excessive daydreaming and introspection and to careful balancing of considerations before reaching a decision. Extraversion was characterized by outgoingness in attention and interest, responsiveness to external stimuli, especially other persons, and impulsiveness. Recognizing that the postulation of only two types failed to do justice to the rich variety of observable patterns, Jung subdivided introverts and extraverts according to the relative dominance of four psychological functions—sensation, thinking, feeling and intuition. But subsequent research has placed most persons somewhere between the type extremes. The theory is useful mostly in calling attention to certain poles of personality and in providing a framework for noting certain trends.

Another widely influential type theory was that of E. Spranger. He began by emphasizing the "dominant value direction" of the individual and held that for purposes of analysis it was convenient to assume the existence of pure or ideal types, one corresponding to each of six major values: theoretical, economic, aesthetic, social, political and religious. This classification was developed into a scale of values by Gordon W. Allport, P. E. Vernon and Gardner Lindzey whereby, as in Sheldon's advance over Kretschmer, the subject is assigned a rating for each of the values.

Types, Traits and Factors

As is now apparent, the concept of types has a limited validity. Its two basic assumptions do not gain strong confirmation from empirical studies. These indicate that a continuous distribution, ranging from one extreme to the other, is likely to be found for any one trait associated with a supposed type, whereas the type concept assumes a piling up of subjects at the two extremes (bimodally). Again, while certain traits are found clustered together interdependently as the type concept implies, the organization is not always of one sort. The peculiar way in which each person has organized the traits of the so-called types has not been taken into account.

For these reasons there has been a gradual shift from interest in types to interest in traits, singly and in their interrelationships. One of the most influential trait theories in the second quarter of the 20th century was that of G. W. Allport, who defined the trait as a psychophysical disposition acquired in the course of experience on the basis of a biological *Anlage*. Allport described traits as arranged in a hierarchy in the individual, some having a cardinal importance in relation to other subordinate ones. He strongly insisted on the existence of individual and even unique traits that might be found in only one person but still demanded to be included in any system of personality. He likewise stressed the individualized organization (congruence) of traits in every person —a view that contrasts with the universalized organization of traits in the type concept. This emphasis on individuality, adapted by Allport from Stern's personalistic psychology, was opposed by him to the exclusive interest of academic, experimental psychology in the generalized or average man. Following Wilhelm Windelband, Allport therefore wished to add the idiographic orientation to the nomothetic (universalized) orientation of general psychology. An almost simultaneous approach to traits developed in England, where K. Pearson's and C. E. Spearman's statistical methods for analyzing such human abilities as intelligence were adapted to the field of personality. Important contributions were made there by Cyril Burt and later by Hans Eysenck, and by L. L. Thurstone, R. B. Cattell and J. P. Guilford in the United States through factor analysis.

Factor analysis is essentially a statistical technique, one aim of which is to reduce a large number of correlated test scores or other assessments to a minimum number of uncorrelated dimensions (or orthogonal factors) by much the same procedure used for resolving physical forces (*see* Vector Analysis). In one common method factors are determined by an automatic analysis of a rectangular table or matrix (*q.v.*) of correlation coefficients into its principal components (or eigenvectors, as they are called). In dealing with personality such researches begin by collecting measures of traits in representative samples of subjects; the correlations between each pair of traits are then calculated, arranged in a matrix, and the analysis proceeds by determining first the factor (vector) that contributes the most matrix variance, then the next factor, and so on, till all the statistically significant variations are taken into account. The most important theoretical conclusion is that factors of personality appear to form a hierarchical structure, in keeping with the neurological views of the structure of the central nervous system. From a practical standpoint, when a factor analysis has been carried to completion, the next step is to invent so-called pure factor tests for measuring the factors directly, or else (since that approach is rarely successful) to devise a method of estimating the pure factors by some mode of weighting the initial assessments.

Some authorities have been led to say that factor analysis does not deliver what it claims: the factors derived by the method are held to depend too heavily on the original selection of tests, which are, of course, only a selection from a limitless number of possibilities; and, again, the factors themselves, once derived, have an uncertain psychological significance which is dubiously aided by the use of letters to designate them or by the arbitrary assignment of trait names that it is hard to justify on psychological grounds. Moreover, the various exponents of factor analysis employ somewhat different mathematical procedures, especially in the critical last phases and, accordingly, bring forth different sets of factors among which it is no easier to choose than among more a priori personality theories. Finally, it has been argued, by Allport and others, that factor analysis does not allow for individuality; the technique radically assumes that all persons reflect a common mold.

To supplement the conventional method of factor analysis, in which scores on a group of subjects are correlated with each other test by test, an inverse method of factor analysis was introduced by Burt and developed by William Stephenson. In it persons, each of whom has achieved a variety of test scores, are correlated with each other. Such person-to-person correlation is, in a sense, a new expression of the earlier typologies, here reapproached on a more empirical—a sophisticated statistical—basis. Moreover, inverse factor analysis has been used not only for relating the several test scores of an individual subject obtained at any given stage, but, taking into account the variability of personality in time, it has been used to compare the assemblage of scores received at one time with those acquired at another. These novel efforts in the use of factor analysis to study individuality are, however, still controversial as to method and meaning.

BIOLOGICAL AND CULTURAL DYNAMICS

The concepts or inferred variables thus far considered refer primarily to the structure of personality—the patterns or other modes of organization that account for the several forms of behaviour that are recognizably personal. In contrast to this approach is one that stresses dynamics; *i.e.*, the forces or drives that direct the personality toward various ends and that secondarily may become attached to certain structures or patterns of function.

Psychoanalytic Theory

This dynamic orientation is, again, a very ancient one; classical writers, like Plutarch, who devoted themselves to biography or morals implicitly used some sort of dynamic theory of personality, and the same is even more obviously true of the great poets, dramatists and novelists of nearly every age. But the 20th-century understanding of personality dynamics received fresh vigour and acquired a theoretical formulation from the writings of the psychologist Sigmund Freud, the founder of psychoanalysis. His interest in the raw, often fantastic data of experience in the individual case led Freud to explore not only dreams but other wayward and seemingly haphazard behaviour, such as slips of the tongue. Thus he developed the theory that both dreams and these other "lawless" or accidental acts were, like neurotic symptoms, the product of psychic determinism at an unconscious level. The concept of the unconscious became for him the basic one.

Just as during sleep, when the ego is not on the alert, the nonconscious forces of personality come into obvious play, so, he asserted, they are present also in the waking state and at every weak point—in fatigue, emotional states and conflict—break through the conventional mask worn by the conscious ego. Much energy is expended by the ego to keep these untamed and unwanted elements of personality from gaining access to consciousness. It was, in fact, in the study of these mechanisms of ego defense in the neuroses, particularly hysteria, that Freud first came to grips with the unconscious forces of personality (*see* also Ego; Defense Mechanisms). A few years later these initial studies were followed by his masterpiece *The Interpretation of Dreams* (1900). In psychoanalytic therapy the aim is to circumvent the ego defenses by the method of free association in the presence of an analyst who permits and, in fact, encourages the patient to disregard in that setting the conventional social amenities. This therapy is a kind of re-education of the personality in which the repressed becomes expressed, the unconscious conscious and the disintegrated integrated. While beginning with the neuroses and with dreams, Freud soon went on to apply the same methods of study and the same concepts to the history of civilization, to the various products of culture—religion, art, literature, etc.—and to the social practices of modern life. The influence of this theory of personality has been considerable, partly, no doubt, because it is itself a reflection of the period of social conflict and tension that contributed to its birth.

Freud based his study of personality on his medical background and hence tended to present his views as biological generalizations with universal application for Homo sapiens wherever found. The unconscious drives of which he wrote and which he discovered in his patients were to him universal instincts modified, to be sure, by family upbringing and social education, but nonetheless rooted in the biology of man. The paradox is that, as compared with other psychiatrists of his time, Freud made much more of environmental factors than they and tended to oppose, by his insistence on psychotherapy, their fatalism. But subsequent criticism has tended to emphasize Freud's implicit belief in the fatalism of the unconscious itself and of its inevitable repetition—as in the classical *Oedipus Rex* of Sophocles, which Freud invoked in naming the oedipus complex. True, the environment has power, it has an effectiveness in Freud's theories; infants can be fixated, adolescents are subjected to intolerable conflicts, etc., and neurosis results. But these influences of the culture are largely negative: they can misshape the personality by deflecting it from the biological goals to which it naturally strives. The positive shaping forces of the culture were scarcely considered in Freud's theories. He was alert to the negative features of religion, which he considered a group neurosis; of art, which he analyzed as a compromise expression of conflict in the artist's personality, etc. The more positive aspects of these cultural phenomena were neglected or ignored by him.

It became the major emphasis in the so-called neo-Freudian schools of Karen Horney, Harry Stack Sullivan (*qq.v.*) and Erich Fromm to compensate for Freud's overemphasis on universal biological forces in personality. In fact, many of Freud's concepts, particularly those concerned with sexuality, were repudiated or radically revised by them. The formative influences of culture have been studied and the findings of social anthropology (*q.v.*) have been invoked to support this newer orientation by showing that different cultures produce different effects on the personalities that develop within them. A healthful ferment has been added to the orthodox Freudian view. (*See* also Psychoanalysis.)

Social Influences on Personality

At this point it is in order to interrupt the exposition of the various concepts offered to explain personality by introducing a summary of general conclusions concerning the role of social influence in the formation and functioning of personality. One such conclusion concerns the importance of infancy in determining basic adult reactions. The child's first experience with any class of stimuli must inevitably have disproportionate significance for his future development. Foremost among such patterns are those concerned with attitudes of security and insecurity. If the child feels wanted, loved and understood, he will tend to be secure in social situations outside the home. Rejection in the family situation engenders insecurity and either withdrawal or hostility subsequently. If, again, the child learns to bow to firm authority in the home, his attitude toward firm governmental authority may become submissive. If, on the other hand, he is subjected to excessive or to inconsistent discipline and so rebels, he is likely to carry over similar rebellious attitudes into his relations with school teachers, employers and government (*see* Family: *Influence of the Family on Individual Personality*).

The family is important in molding personality not only because so many parent-child relationships are prototypes of adult situations, but also because the child there unconsciously assimilates many attitudes and social expectations. Children are extraordinarily sensitive to vocal inflection, facial expression and other manifestations of which adults may be quite unaware. Sarcastic remarks about labour unions, Negroes, people who are too aggressive and those who are not ambitious enough have their effects on the child listener. The division of society into men *v.* women, bosses *v.* workers, leaders *v.* followers becomes sacrosanct to him and he develops a rigid concept of how people ought to act when they assume a certain role. Moreover, parents impose standards of behaviour by reward or punishment. Much of this learning goes on before the acquisition of language; *i.e.*, it is unconscious and deeply implanted. Sexual experimentation, for example, is normal to young children, but severe punishment may cause the child not only to abandon habits of sexual play but also to forget (repress) that he ever thought of such acts.

The school system has a strong influence on the growing child's personality. Occasional arbitrary discipline, overrigid work assignments and the necessity for treating diverse individuals alike in crowded classes are examples of undesirable practices. Good teachers, on the other hand, may become models whom the child will imitate. The content of education is also significant. Narrow, nationalistic, prejudiced teaching in history and social studies not only misleads the child but gives him an outlet for repressed hostility that tends to fixate his manner of thinking on a low level. Finally, the competitive system of grading, with its emphasis on invidious personal comparisons, is open to criticism.

Economic conditions have been shown to have a significant effect on the personalities of both children and adults. Poverty, for example, tends on the whole to distort personality development. The alleged beneficial effects of hardship have, for moralistic reasons, been largely overrated. To note this point is not to suggest that maladjusted (neurotic or delinquent) personalities are never found in the upper economic classes. But on a percentage basis the child in a better-class home has a better *chance* of reaching maturity with a well-balanced personality.

Values, ethics and character standards are all functions of social influence. With respect to these complex variables the child at birth appears to be a blank slate. Potentially he may be molded to satisfy his biological need for security by selfishly protecting his interests in the face of competition, or he may learn to gain the very same end by altruistically sharing with and receiving from others. His later view of human nature and ethics will follow as a rationalization fitted, as verbalization becomes possible, to justify the unconsciously learned patterns of social behaviour. One thus sees that ideas of right and wrong, beliefs as to the proper ways of behaving socially, or gaining one's ends, etc., come basically from behaviour patterns that have been inculcated or have been acquired from observation and imitation of those in closest contact with the growing child. The improvement of the intimate environment and the education of children is therefore held to be one of the chief avenues for developing more mature personalities. (*See* also Child Psychology and Development; Psychology, Social.)

Experimental Psychodynamics

The cultural critique of Freud within psychoanalysis itself was supplemented by a critique on grounds of scientific method

from the ranks of academic psychology. Since Freud's findings were largely based on his clinical work with neurotic patients, it was reasonable to ask whether his concepts would stand up under experimental scrutiny. At the same time opportunity might be taken to probe the general applicability of Freud's theories to normal persons. (Freud himself regarded his theory as a psychology of the normal and the abnormal indiscriminately.) What resulted was not, however, merely a critique of Freud: it reflected the particular conceptual orientation of the research centres that performed the experimental work and led to a development that may be conveniently called experimental psychodynamics. In most of these investigations the aim was to study personality with a dynamic theoretical basis borrowed from or based on the insights of Freud but intended to offer new and more rigorous concepts for handling the same psychological data.

Carl Jung (*q.v.*), who was for a time a close associate of Freud, conducted what may be regarded as the earliest studies in experimental psychoanalysis, presented in his book on the word association method (1906). But the first concerted program of this sort was conceived and conducted at the Harvard Psychological clinic about 25 years later. In that laboratory, beginning around 1930, Rosenzweig instituted an experimental program devoted to the clarification of psychoanalytic principles such as repression. This work led to a set of concepts under the heading of frustration theory that took frustration as a key concept for analyzing personality dynamics. The program of research resulted in the construction of the Picture-Frustration study, mentioned above. By combining detailed investigations of biography and projective methodology with frustration theory, this view was later broadened to include growth and creativity in its theory of personality. Henry A. Murray, in another departure, formulated a theory of personality in which the concept of need was made pivotal. In collaboration with Christiana D. Morgan he developed the Thematic Apperception Test, cited above. Through the use of a wide variety of experiments, tests and interviews, supplemented by a diagnostic council of the principal investigators who all worked with the same subjects, the effort was made both to fathom personality dynamics in the momentary cross section and to reconstruct in selected instances the longitudinal life history. The result appeared in *Explorations in Personality* (1938).

At the Yale Institute of Human Relations a research program was pursued with a different ground of conceptualization. Behaviourism (*q.v.*) was the point of view there prevalent, and concepts of learning (*q.v.*) theory played the crucial role in the work of this group (Clark Hull, John Dollard, Neal Miller, Robert Sears and O. H. Mowrer). An interpretation of aggression as instigated by frustration was formulated and published (1939); the process of psychotherapy, including psychoanalysis, was reconceptualized with the principles of learning as a basis (1950). More fundamental even were the numerous studies of animal behaviour (*q.v.*), especially of the white rat, in controlled situations with dynamic significance (*e.g.*, fear, anxiety, conflict), some of which were planned as analogues of human psychodynamic principles (*e.g.*, regression). In soviet psychology, which historically initiated the behaviouristic approach, this emphasis is carried to an exclusive consideration of social conditioning, on the one hand, and organic, physiological function, on the other, the dynamic theories of psychoanalysis and of existentialism (*see* below) being completely rejected. One here sees how personality theory is, in part, an expression of cultural forces. From the soviet standpoint, psychoanalysis, and even more so existentialism, rationalizes the unhealthy individualism of capitalistic culture.

Self-Realization and the Self-Concept

A fruitful source of concepts for understanding personality has been psychotherapy (*q.v.*). While other psychologists, as above noted, worked with psychodiagnostic devices (*e.g.*, projective methods) or attempted to unravel motivation through experiments in the animal laboratory, a third group utilized the interaction of therapist and patient with actual human problems posed for solution. Freud was, of course, the pioneer in this field of work in his special domain of psychoanalysis, but in psychology proper Carl Rogers led the way. Beginning with a minimum of theory, Rogers recorded and studied therapeutic interviews of neurotic or merely troubled clients in an effort to discover objectively what changes occurred and how they were effected. By systematic exploration of this kind he was eventually led to a view of personality in which the so-called self-concept was pivotal and in which self-realization in the process of normal and abnormal development came under close scrutiny. Rogers was led to the theory that the individual normally has a drive toward self-development which when impeded by conflict leads to symptoms of disorder. The opportunity to review these blocks to growth in a permissive therapeutic situation proved an important means toward overcoming them, quite apart from any theoretical interpretation of the behaviour such as that given in Freudian psychoanalysis. The relationship between therapist and client was in itself salutary.

This conceptualization of the therapy of the neurotic in terms of autonomous growth was reinforced from other directions. For example, the neurologist Kurt Goldstein, first in Germany and later in the United States, studied cases of brain injury by inquiring in each instance how the individual adapted to his defect and managed somehow to cope or come to terms with it. Even in such grave situations, the capacity of the human organism for self-adjustment was shown to be remarkable, according to Goldstein's findings.

Abraham Maslow, working at the other extreme with normal and gifted persons, tried to throw light on the process of self-actualization. What, he asked, contributes in fortunate cases to successful self-expression and what, on the other hand, defeats such an outcome? From these diverse directions contributions have been made to a better understanding of the dynamics of frustration, growth and creativity.

In the theory of personality that Rogers gradually built up from his investigations of psychotherapy, the concept of the self played a leading part. Moreover, he was concerned less with his own concept of the subject's self than with the subject's self-concept. Changes in psychotherapy were interpreted as changes in this self-concept—in the way the client (or patient) modified his view of himself. The so-called real environment—if we leave aside that part of it which, as a minimum requirement for life, supplies the biological necessities—is important from the psychological standpoint only in the measure that and in the way that it is filtered through the subject's perception of it and of himself in relation to it. For this reason, the therapist in seeking to change personality works very largely with the client's own concept of himself, which, of course, in turn involves his feelings of relationship with others.

It is thus appropriate to consider, at least briefly, this concept of self. It is inferred by the psychologist that the newborn infant has no conception of himself. It is only in the course of the first year or two of life that the sense of personal identity is acquired. The baby's earliest interest in his own mirror image, for example, is often regarded as pointing to the dawn of this awareness. But there are, of course, many ramifications and dimensions of the subject's self-identity, and attempts have been made to trace the changes in the self-concept (or sense of identity) from infancy through childhood and adolescence to maturity and after. Closely connected with the achievement of a stable self-concept is the degree of security that the person has achieved by virtue of earlier experience. If in the earliest months of life the child has been made to feel secure, he more readily develops a stable sense of his own identity which stands him in good stead in bringing to fruition the potentialities of his personality and in utilizing the opportunities of his environment. It has been often stated, for example, that the image which the person has of his own body—the body image—is an important nucleus of his conception of self. If the body image is defective by virtue of a "real" or imagined crippling, an element of permanent instability may enter the self-concept. But, of course, the current secure or insecure situation in which the person has to exist is likewise important in reinforcing or impairing the sense of identity. One dimension of this influence is the feeling of hope or hopelessness

that may affect the self-concept in profound ways.

This approach to personality via the self-concept seems to many psychologists to refer back to older philosophical speculations; *e.g.*, those of German idealism. To some extent this criticism is doubtless valid, and it has led many investigators to avoid this form of personality theory and to prefer a more behaviouristic variety.

Phenomenology and Idiodynamics

The point of view of Rogers has been sometimes designated phenomenological—a term that gained currency beginning with E. Husserl (*see* Phenomenology). Starting as a branch of epistemology, European phenomenology strongly influenced developments in experimental psychology, particularly the studies of perception that gave birth to the German school of Gestalt psychology. While various theoreticians have given different interpretations to phenomenology, all have agreed in using the term to denote a discipline devoted to the analysis of immediate experience. As such, this discipline challenges the commonsense concept of the real world, the external environment as conceived by the biologist, and attempts to examine systematically the subject's knowledge of his world as an interdependent aspect of his self-knowledge. Rogers in his psychotherapeutic studies was little influenced by the more technical aspects of philosophical phenomenology. These are more clearly discernible in the approach of existential psychiatry. This orientation, dating from the second quarter of the 20th century, concerned itself initially with experiences of the schizophrenic and other mental patients, but its avowed implications extend to all the data of personality.

Among the Gestalt psychologists, Kurt Lewin made important experimental and theoretical contributions which belong in the framework of phenomenology. He generally ignored the remote history of the individual and subordinated it to the analysis of the momentary psychological situation. This cross section was analyzed with the aid of field theory in concepts adapted from the physical sciences and mathematics (vector analysis and topology). Lewin's aim was the prediction of specific behaviour that went beyond the statistical or actuarial objective. He maintained that psychology must posit and work within a different space from that employed by the physicist—a psychological or hodological space with properties of its own. Though purporting to bear directly on problems of personality dynamics, Lewin's work had more immediate influence on social psychology (group dynamics) than on the psychology of the individual.

A last conceptual approach that belongs under the general heading of phenomenology is idiodynamics. In this view the personality is conceived as an idioverse or idiocosm—an individual universe of psychological events (experiences)—which can be categorized and analyzed to show temporal and motivational consistencies. The universal norms of general psychology and the group norms of cultural anthropology here give way to individual norms in terms of which the personality operates and is to be understood. But this view has been advanced as but one approach to a composite science of psychology; as a complement to the several other dimensions of a complete analysis of personality.

RECONCILIATION OF CONCEPTS

The foregoing survey of concepts, ranging from the organic to the strictly psychological (subjective, phenomenological), may be interpreted in one of two ways: (1) as indicating, if taken at face value, the broad diversity of competing views in the field of personality theory; (2) as portraying the multidimensional nature of personality (and of psychology) which, of necessity, approaches the person—the human organism—at diverse but complementary levels or axes. On this latter view a composite set of levels must be plotted in a complete chart of personality; each level provides working concepts for specific problems related to it. *See* also references under "Personality" in the Index.

PERSONALITY DISORDERS, which are manifestations of defects in personality structure, are characterized by lifelong behavioural patterns that are inadequate or inacceptable. These disorders may be categorized as personality pattern, personality trait or sociopathic personality disturbances.

See Alcoholism; Behaviour Disorders; Drug Addiction; Psychiatry: *Personality Disorders;* Sexual Deviations.

PERSONAL PROPERTY, one of the two main divisions of the English common law of property, the other being "real property" (*see* Real Property and Conveyancing, Laws of). This differs substantially from the Roman law division of property into immovables (land) and movables (goods, animals, etc.) which was adopted in most civil-law countries. The difference is that personal property embraces a body of interests in land, known as "chattels real." The explanation is historical.

In medieval England there existed certain forms of lawsuits known as "real actions," in which possession of land could be recovered by one having a freehold estate (*i.e.*, a life estate or an inheritable estate). Land interests of less than freehold were known as chattels real and comprised what became the various kinds of leasehold interests (*see* Landlord and Tenant).

The English term personal property is thus synonymous with chattels, the latter being divided into chattels personal (the equivalent of movables) and chattels real (leaseholds in land). Chattels personal are divided into choses in possession (tangible movables, including animals, merchandise, goods) and choses in action (intangibles, including promissory notes and rights of action). Tangibles in this context means physical things capable of being seen, felt, eaten, worn or driven.

The word "goods" is occasionally used synonymously with personal property, more frequently as a synonym for chattels personal, and sometimes in a still more limited sense as meaning tangible inanimate things as distinct from animals, money or intangibles. Important differences between real and personal property at common law included differences in their transmission at death. Until the time of Henry VIII, English law permitted only personal property, not real property, to be left by will. If he died intestate, the owner's real property descended to his heir (under primogeniture, his eldest son) whereas his personal property was distributed by his administrator among his next of kin (*i.e.*, his surviving spouse and children or, lacking children, the brothers and sisters, etc.). (*See* Intestate Succession.)

Categories of Property.—Distinguishing between different categories of property is sometimes difficult. Gold is a tangible; circulating gold coins are both tangibles and intangibles but have a greater value as intangibles. Ancient coins are now tangibles only; circulating paper money is an intangible almost exclusively. Promissory notes are considered intangibles. An autograph is, however, tangible. Therefore a promissory note of a famous historical personage might be valuable solely as a tangible; the promissory note of a solvent living "nobody" would have value solely as a chose in action, a claim for the money it promises to pay.

Similarly, growing crops form part of the real property, but upon being actually (or, sometimes, constructively) severed, they become personal property. An undoubted movable may, after being permanently affixed to or appropriated for use with the land, become part of the real property. Thus, permanent buildings become part of the real property. On the other hand, the soil itself, upon being taken from the surrounding land, becomes a chattel personal. Similarly, corporate stock shares are intangible chattels personal, even though the corporation assets consist entirely of real property.

A few anomalous chattels, not strictly fixtures but so closely identified with land that they are treated as if they were real prop-

erty, are: (1) heirlooms (*q.v.*); (2) title deeds (particularly in England, because of the lack of universal recordation of deeds); and (3) keys to the door of a building.

In cases both of fixtures and crops, a thing may be personal property as between A and B, yet be treated as real property between A and C. Improvements installed in a building by a tenant may remain his personal chattels as against his landlord, although had a landowner sold a building containing his own improvements of the same kind, such improvements would have passed as real property to the buyer as against the seller.

By the judicial fiction known as equitable conversion, courts in England and the United States will for some purposes treat particular land as if it had been converted into personal property, or personal property as if it had been changed into land, where the terms of a valid will, contract or settlement had directed such change. Thus, an enforceable contract to sell land is said to work an equitable conversion, whereby the land is treated as if it already belonged to the vendee, with the price being regarded as belonging to the vendor.

If the landowner-vendor dies before the actual conveyance, his legatees are entitled to the price as personal property. The purchaser takes the land upon paying the price; if he dies before paying, his heirs get the land, his administrator paying the price from the purchaser's funds.

Personal property embraces almost anything in existence, other than real property, that is capable of being enjoyed or used. Electric current is tangible property although invisible and not safely felt, being capable of manufacture, measurement and use. It is often said that there is no property in air or water, yet compressed air or bottled water is certainly property.

Blackstone declared that in English law the heir had no property in the bones of his ancestors. The prevailing view in the United States, partly by statute and partly by decision, is that the surviving near relatives of a deceased person may not only enjoin wrongful interference with his ashes but may also recover in damages for such invasions of their rights (whether called property rights or personal rights). The English common law declared that wild animals ceased to be property whenever they made good their escape, but several U.S. decisions have rejected this rule as to nonindigenous menagerie animals or those kept on a commercial fur farm.

Buying or Selling.—Ownership of personal chattels may be acquired, lost, transferred or affected in various ways. One method is by buying or selling. If A wants to buy an automobile from B, A may either: (1) buy it outright for cash; (2) exchange other goods for it (barter); (3) buy it by absolute sale but on credit; (4) take it under a "lease" (bailment agreement) containing an option to purchase on the completion of a stated number of rental payments, aggregating its price, without A being obligated to become the buyer or complete the payments (an example being the hire-purchase transaction widely used in England); (5) buy it on conditional sale, in which case A gets immediate possession, but the seller, B, retains title as security until the full price is paid, B being obliged to transfer title when full payment is made and A being legally bound to make such payment (*see* INSTALLMENT CREDIT; in those United States jurisdictions adopting the Uniform Conditional Sales act, methods 4 and 5 are usually treated alike, and likewise under the Uniform Commercial code); (6) buy it "subject to return," this being a present sale with an added privilege in A to call off the transaction within a specified time if not satisfied; (7) buy it "on approval," this being a bailment with an option to buy and becoming a sale only upon the bailee either expressly accepting the goods, failing to reject or return them within the time specified, or having used them inconsistently with his not having taken title. Ownership may also pass by involuntary sales, including judicial sales, tax sales and foreclosure of liens.

If the seller was neither the owner nor one having authority from the owner to sell, or was selling stolen goods, the question arises whether the good-faith purchaser acquires good title against the unconsenting true owner. Under Roman law he would not, but French law in general protects the purchaser. Anglo-American law usually protects the unconsenting true owner, but with certain exceptions. In England, but not in Scotland nor in the United States, these exceptions include the "market overt" doctrine protecting a bona fide purchaser of goods at an established fair or from any City of London shop regularly selling such goods. (*See* SALE OF GOODS.)

Gifts.—Another way of acquiring property is by gift. By classifying as conveyances gratuitous transfers of real property and chattels real, and treating testamentary dispositions under wills, Anglo-American law restricts the meaning of gifts to gratuitous transfers of personal chattels taking effect on delivery in the lifetime of the donor. Such gifts are divided into two categories: (1) gifts *inter vivos* ("between living persons") and (2) gifts *causa mortis* ("in case of death," also known as *donatio mortis causa*); the principal difference being that gifts *causa mortis* are revocable. The later Roman law assimilated *donatio mortis causa* and legacies, and permitted such gifts much more readily than do English and U.S. jurisdictions. Anglo-American law limits *causa mortis* gifts to instances in which the donor contemplates impending death from an existing illness or injury. U.S. decisions conflict as to whether such a gift may be made in contemplation of suicide. Gifts *causa mortis* fail automatically if the donor survives the peril from which he envisaged death. A majority of Anglo-American decisions permit the donor to revoke his *causa mortis* gift by any unequivocal act or a subsequent inconsistent specific bequest, even though he later dies from the contemplated peril. A gift *inter vivos* is irrevocable but is voidable where the donor lacks capacity, or where fraud or undue influence procured the gift, and fails if donee refuses to accept it. French law does not recognize gifts *causa mortis* but holds gifts *inter vivos* to be revocable for cause, notably by a child being born to the childless donor or by judicial revocation for "ingratitude" (cruelty toward, refusal to support, or attempted killing of the donor). French law requires that a gift *inter vivos* and its acceptance be embodied in formal documents, whereas Anglo-American law permits purely oral gifts but insists on delivery. Delivery normally includes delivery of possession, but signifies in this context a manifestation that the ownership and control have passed from the donor and that he has given up the right to withdraw the gift. (*See* also LEGACY.)

Other Methods of Acquiring or Losing Title.—These include:

Adverse Possession, Prescription or Limitation.—Under the majority view in the United States, paralleling a common-law doctrine applicable to land, a person openly and exclusively holding another's chattel personal under claim of right and for a specified continuous period of years may acquire ownership by operation of law. Under Roman and French law this is acquisition by prescription (*q.v.*). In England the statute of limitations protects such a holder and his successors from a suit by the past owner; a new title was not thought to arise but a 1939 statute provides that the barring of the past owner's right to sue also destroys his title.

Abandonment.—The common law permits a person to relinquish his title to a chattel (but not his ownership of land) by placing it out of his possession and control and intending never to claim it or exercise further control over it. Loss by abandonment occurs instantaneously when both of these elements coexist.

Accrual to the State.—If the owner dies intestate and without a spouse or relatives, his personal property accrues to the state. Personal property may be taken for public use where necessary, and it is sometimes forfeited because of the criminal conduct of the owner, but constitutions in the United States require compensation for eminent-domain takings and permit forfeitures only within narrow limits and under specific statutes; *e.g.*, forfeiture of automobiles used in violating liquor or narcotics laws. (*See* EMINENT DOMAIN; CONFISCATION AND EXPROPRIATION.)

Extinction of the Res.—Ownership may cease because the goods have been physically consumed or destroyed, or have lost their identity by becoming merged with real property or with other chattels. Under civil-law rules adopted by the English common law a chattel, by being greatly improved by labour or by being added to other materials, may become part of a new thing and

cease to exist apart from that new thing. Paint applied to a building or to furniture ceases to exist except as an integral part of such building or furniture. Where one owner willfully or fraudulently commingles his own goods with like goods of another owner and without the consent of the latter, resulting in a confusion of goods which renders it impossible for each owner to identify his own or ascertain his share of the commingled mass, the commingler may lose his entire interest in the mass.

Court Judgment.—Where A falsely claims ownership of something belonging to B and a court judgment establishes A's title, the judgment in reality destroys one title and creates another, but in theory it has simply vindicated the pre-existing title. Where C wrongfully converts to his own use, or to the use of a third person, the chattel of D, and D recovers judgment therefor against C in the common-law action of trover or its modern statutory equivalent, the satisfaction by C of that judgment creates a title in C. In effect, this is a purchase forced upon C by reason of his wrongful conversion of the thing.

Numerous situations arise in which an owner parts with possession of his chattel without ending his title or ownership. If he loses or mislays it, the chattel remains his; although the finder is by the common law entitled to retain possession meanwhile as against other persons, including the finder's bailee or one finding it after the first finder lost it. The English and U.S. cases show considerable conflict as to the rights of the finder as against the owner of the land on which the thing was found. Some courts stress the distinction between mislaid and lost goods; others inquire whether the place of finding was one to which the public was freely admitted or was reserved by the landowner for his private use; if the finder was an employee of the landowner and made his find as part of his duties or in a place to which he was admitted solely by virtue of his employment, the trend of decisions in the United States allows the landowner permanent possession of the thing as against the finder. In both England and the United States the landowner is normally protected as against a trespassing finder. (*See* also SALVAGE.)

Bailment.—Apart from transactions involving a transfer of ownership, the most important legal relationship regarding chattels personal is termed bailment (*q.v.*). Chattels real cannot be the subject of bailments. A bailment arises in almost any situation in which one person (the bailee) lawfully has possession of the goods of another (the bailor). Bailments may be either for the sole benefit of the bailor (as where one friend gratuitously stores another's goods), for the sole benefit of the bailee (as where one person gratuitously lends his watch to another), or for mutual benefit (as where the owner lets another use his goods for an agreed rental; or where the bailee is to store, transport or improve the goods for and at the expense of the owner). For some purposes the finder may be treated as a gratuitous bailee. An involuntary bailment may arise where the goods of one man come into another's possession without the latter's consent. The indispensable element of a bailment is possession by the bailee. If the repairman comes to the house to fix the clock, he is no bailee; if the owner leaves the clock at the repair shop, a bailment exists. Railroads, van companies and other common carriers are bailees of the goods entrusted to them for shipment. Particularly in the United States, to lessen income taxes and to reduce the amount of capital they must invest, countless companies have become bailees of automobiles, ships, machinery or equipment instead of buying them.

Although bailments may arise without either a written agreement or a contract, these "lease" bailments usually involve a formal written lease (so-called by analogy to a lease of land, but the transaction remains a bailment), and many clauses in such instruments are directly copied from written leases of land. In many instances, therefore, litigation involving such bailment documents is decided by analogy with the corresponding rule regarding leases of iand. In some jurisdictions certain bailment clauses are unenforceable as against public policy; others will be given effect but only if specifically agreed to and even then will be narrowly construed. Agreements freeing a bailee from liability for his negligence illustrate both of the foregoing categories.

In a bailment, title remains in the bailor and, in the absence of contrary agreement, he is entitled to any profits or increase in value, and to the offspring of bailed animals. Unless he agrees to be an insurer of the safety of the goods, the bailee is liable only if their destruction, loss or damage results from his failure to care for them properly. The measure of his duty of care depends in part on whether the bailment was for his sole benefit or for the sole benefit of the bailor, or for mutual benefit; in part, it depends on whether the bailee held himself out as engaged in a "common calling" (that is, innkeeper, common carrier or public warehouseman) or whether a statute or the specific agreement altered the ordinary rule of liability.

One type of bailment, made for the express purpose of giving the bailee a lien on the goods as security for performance of an obligation, usually an obligation to pay money, is known as pledge (*see* PAWNBROKING).

Actions at Common Law.—The Anglo-American law of personal property was shaped considerably by the common-law forms of personal actions. To illustrate: if A chopped down B's tree, B could choose from a variety of personal actions. B could either: (1) sue A for trespass to the land, recovering the amount by which the loss of the tree reduced the land value; (2) sue A in *trespass de bonis asportatis* for the value of the tree after severance; (3) sue A in trover for conversion of the severed tree; or (4) by replevin recover the severed tree itself. If A had sold the tree to C, B could still recover from A in any of the foregoing except replevin, or could instead (5) sue C in trover or (6) sue A in assumpsit (as if A had sold the tree for B).

Property is used throughout this article in its usual and practical sense, as referring to things and intangibles, ignoring the theory that in a strictly technical sense property is neither land nor goods but rather the interest or estate ("bundle of rights, privileges, powers and immunities") which a person has in such land or goods as against other persons.

PERSPECTIVE is the method used in drawing to portray three dimensions on a two-dimensional surface.

History.—Artists have been experimenting since the Stone Age in their attempts to express a feeling of space and solidity. A reindeer herd was etched on a fragment of bone 15,000 years ago, and the illusion of distance was created by showing the legs and antlers as if seen beyond the fully sketched animals of the foreground. The artist of ancient Egypt discovered that his main perspective problem was showing a single important object in the necessary three dimensions. This he expressed in his own way by drawing a combination of plan and side view. A Pharaoh carrying a circular tray of sacrificial offerings was drawn in this manner. The top view of the tray is shown in half by means of a semicircle. On this half-tray is the sacrificial food as it would appear when viewed from above. This stylized method of expressing a third dimension persisted in Egyptian drawing for 3,000 years.

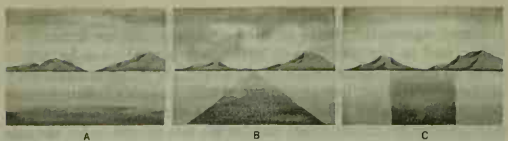

FIG. 1.—A SIMPLE PERSPECTIVE DRAWING OF TREELESS LEVEL COUNTRY, WITH PERSPECTIVE AND NONPERSPECTIVE RENDERING OF A HIGHWAY

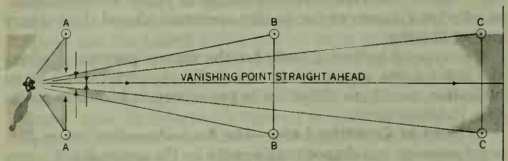

FIG. 2.—LOOKING AT A LEVEL HIGHWAY (TOP VIEW): AS DISTANCE INCREASES, THE HIGHWAY APPEARS TO DIMINISH IN BREADTH

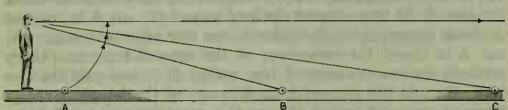

FIG. 3.—LOOKING AT A LEVEL HIGHWAY (SIDE VIEW): THE HIGHWAY APPEARS TO RISE

In America, northwest Indian artists developed a unique method of showing the front view together with both the left and right sides of a person or an animal. The creature was drawn as if it were split down the back and then flattened out like a hide. Each side of the head and body thus became a profile facing the other.

Chinese artists created landscapes that had excellent feeling of distance and space by skillfully arranging the natural contours of land, water and foliage. When buildings were drawn it was necessary to show the parallel horizontal lines of the construction. Isometric drawing was used. Isometric drawing is a simulation of perspective drawing wherein parallel lines are drawn parallel, instead of converging as in true perspective. Often foliage was used in the drawing to crop these lines before they extended far enough to cause the building to appear warped. These isometric arrangements made an attractive pattern of interposing line.

The early European artist used a perspective which was an individual interpretation of what he saw rather than a fixed mechanical method. It was not until the first half of the 15th century that the Italian painters made perspective drawing an exact science by the use of the horizon line and the vanishing point.

At the beginning of the Italian Renaissance the mathematical laws of perspective were discovered by a Florentine architect, Filippo Brunelleschi (1377–1446), who worked out some of the fundamental principles. Masaccio (1401–*c.* 1428) began using the method and within a short period brought about an entirely new approach in painting. A style was soon developed using configurations of architectural exteriors and interiors as the background for religious paintings. This gave the new science the opportunity to expand freely. One of Brunelleschi's contemporaries Paolo Uccello (1397–1475) compiled these principles into book form and in doing so became the original authority in the field of perspective projection.

In modern times, perspective has an important part in the work of artists as well as in idea presentations of architects, engineers, landscape specialists and industrial designers. It furnishes an opportunity to view the finished product long before it is begun.

Technique.—The simplest perspective drawing that can be made is a single horizontal line across the paper. The word horizontal in itself suggests the natural horizon (*i.e.*, the distant line where the earth or sea apparently meet the sky). By drawing this horizontal line the artist has created the illusion of space and distance as far as the eye can see. A sailboat added and a few clouds above the line complete a picture of the sea in the distance meeting the sky. If the sails of the boat shut from view a segment of the horizon, this places the horizon farther in the distance than the boat.

In a level treeless country a distant mountain range may be seen beyond the horizon (fig. 1A). The curve of the earth's surface is so gradual that it gives the impression of being flat. Yet mountains can be seen beyond this curvature. The superstructure of ships at sea can be sighted long before the hull is seen. A distant island appears to rise out of the sea as it is approached. The horizon therefore is seen as a continuous line between the observer and distant objects. This line is curved, but the curvature is so slight it is usually ignored in drawing.

The colours of distant objects are softened by the atmosphere into bluish tones. This atmospheric colour effect in itself creates an impression of distance and is called aerial perspective.

A highway built across the plain may be drawn as two straight lines meeting at a point on the horizon (fig. 1B). These lines

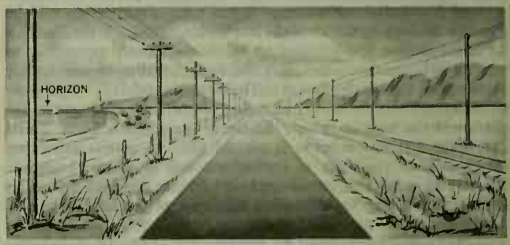

FIG. 4.—THE PERSPECTIVE OF PARALLEL LINES

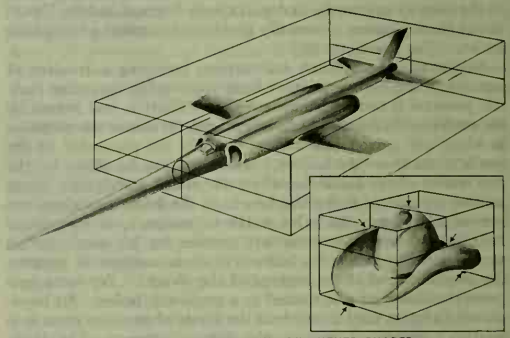

FIG. 5.—THE PERSPECTIVE OF CURVED SHAPES

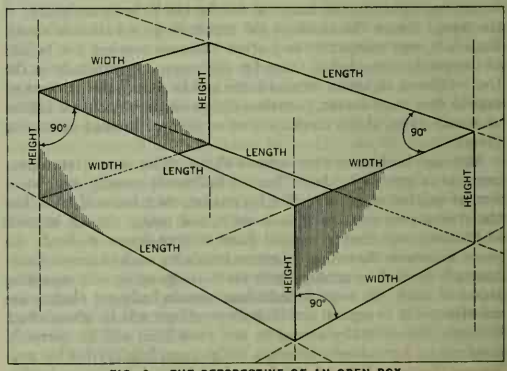

FIG. 6.—THE PERSPECTIVE OF AN OPEN BOX

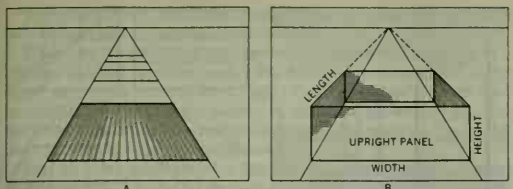

FIG. 7.—ONE-POINT PERSPECTIVE

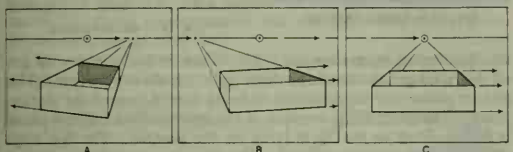

FIG. 8.—THE ESTABLISHING OF VANISHING POINTS

represent the two curbs which are uniformly parallel throughout their lengths. Why are the curbs drawn as converging lines rather than parallel lines, as in fig. 1C?

Fig. 2 shows the top view of a person standing in the centre of the highway. For him to see both curbs near his feet his eyes must take in a wide area at the section marked AA. Twenty feet beyond, at section BB, he sees the same width but it appears considerably narrower than at AA. As he looks beyond to CC it appears still narrower and when he looks as far as he can in the distance, to the horizon line, he sees that the width has narrowed to a mere point. Beyond this point no more highway is visible. This point is called the vanishing point.

The side view of the same situation is shown in fig. 3. The person must look down in order to see the highway near his feet at section A. To look at B, the section 20 ft. beyond A, it will be necessary to raise his eyes. This is also true for section C, and so on, until he is looking straight ahead along a line that is level with his eyes. He is then looking directly at the vanishing point of the highway. Fig. 4 illustrates how level highway appears to rise to eye level at the horizon.

Two conclusions may be drawn: (1) The natural horizon and the artist's eye level are at the same height. This is true whether he is lying on the ground or sketching from an airplane. The horizon seems to rise to meet the eye level. (2) The vanishing point of a system of horizontal parallel lines is always on the horizon line. There can be systems of parallel lines in a picture that do not meet at the vanishing point. One system is made up of upright or perpendicular lines. The other system comprises the horizontal lines which are parallel to the horizon. A general rule covers these systems: parallel lines do not converge to a vanishing point if they are parallel to the picture plane (the surface on which the picture is executed).

In nature there are very few square corners but man's most common form of construction is the box. Houses and furniture, books and skyscrapers, all are modifications of box designs. A solution for most perspective problems may be derived from a proper understanding of the box. The drawing of curved forms, such as shoes, hats, automobiles and airplanes, becomes simplified when these objects are fitted into boxes (fig. 5).

The box has two upright sides, a top, a bottom and two ends—six planes in all (fig. 6). There are 8 corners where 3 planes meet at right angles to one another and 12 edges where 2 planes join. These 12 edges or intersections of the planes are represented in the drawing as lines which will be referred to in groups of four: length lines, width lines and height lines.

One-Point Perspective.—To draw a box in one-point perspective, two lines may be drawn converging at a horizon line, as in the case of the highway (fig. 1). Let a section represent the bottom of the box (fig. 7A). Upright end panels can be placed on the section lines (fig. 7B). The top and the sides can be represented by drawing two upper length lines from the top corners of the near panel to the vanishing point. The height of the far end panel is determined by the intersection of the length lines with the verticals or height lines.

The entire projection may be inverted so that the vanishing point is below the object depicted, as in Masaccio's "Trinity" at S. Maria Novella, Florence. In Florence 70 years later Leonardo da Vinci (1452–1519) painted his famous "Last Supper" using the one-point perspective. All the perspective lines of the room lead to the vanishing point at the head of Christ.

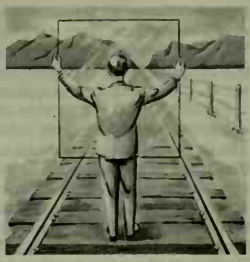

FIG. 9.—THE PICTURE PLANE

Two-Point Perspective.—If the box is rotated slightly the vanishing point of the length lines will move along the horizon accordingly (fig. 8A), until it passes out of the picture, although it will still remain on the horizon line. As the width lines move they are no longer parallel to the plane of the picture and it is necessary to establish a vanishing point for them. This point is also on the horizon line (fig. 8B). In two-point perspective there are two vanishing points: one for the width lines and one for the length lines. If the box is rotated farther until the newly established point coincides with the central position of the original vanishing point, the length lines will be parallel to the picture plane, and the box is again in the position of one-point perspective, having been rotated 90° (fig. 8C). The distance between the vanishing points in two-point perspective is governed by a simple ratio. In order to understand this it is necessary to become further acquainted with the use of the picture plane. (*See* fig. 9.)

Perspective Projection.—The picture plane is represented as an upright transparent surface. The artist stands facing it on a level plane called the ground plane. He looks through the picture plane at the object, also resting on the ground plane (fig. 10). In this instance, the object he wishes to draw is the box. The ground line (GL) is the line where the picture plane rests on the

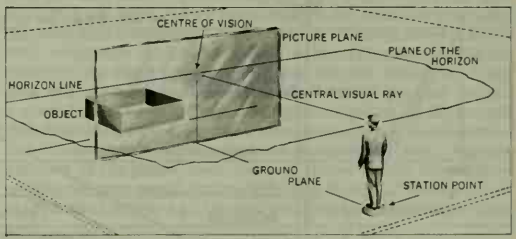

FIG. 10.—THE PERSPECTIVE ARRANGEMENT

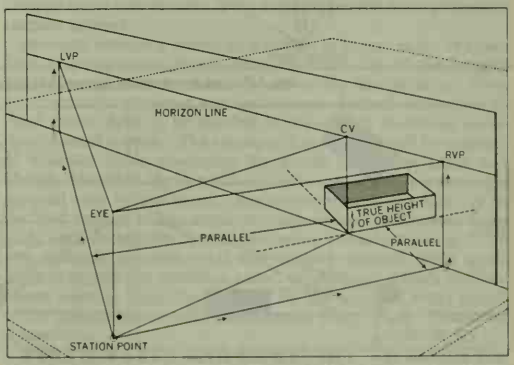

FIG. 11.—LOCATING VANISHING POINTS

ground. The artist stands on the station point (SP) and sees the scene before him from an eye level viewpoint, called the eye. When he looks directly at the picture plane (along a line perpendicular to it) he is looking along a line called the central visual ray (CVR) which lies on a plane called the plane of the horizon.

Everything that can be seen above this plane is said to be above eye level; everything seen below this plane is below eye level. The central visual ray intersects the picture plane at a point called the centre of vision (CV). A horizontal line drawn through this point is the horizon of the picture. It is the line where the plane of the horizon intersects the picture plane. If the artist is seated, the horizon is lowered; if he views the object from a stepladder, the horizon raises accordingly. The object also may be raised and the picture plane may be moved closer to the artist or back against the object. These arrangements allow a great deal of freedom.

According to theory the artist can now locate all the necessary points and lines of the object and draw them where the visual rays (VR) show them on the picture plane. The centre of vision becomes the vanishing point of a drawing in one-point perspective.

The two-point perspective arrangement can be made by rotating the object (fig. 11) to the desired view. For convenience the picture plane is placed against the corner of the object. By doing this the height is actually on the picture plane in true measurement. In this way the process of projection is made simpler and easier to visualize.

The station point is chosen at any desired distance from the object and the view from any desired height above the ground. When the eye height is established, two lines from the eye are extended parallel to the two sides of the box. The two lines form a right angle and each meets the picture plane on the horizon line. The points where they intersect the horizon line are the left vanishing point (LVP) and right vanishing point (RVP). The same points can be reached by drawing the two lines on the ground from the station point to the picture plane and then up to the horizon line (indicated by arrows, fig. 11). Then it is necessary to get all this arrangement flattened down onto one sheet of paper. The picture plane may be visualized as being moved toward the station point. The ground line remains in the new position but the plane is folded down so that it is lying on the ground. The top edge of the picture plane is ignored. The plane remains in its original position touching this trace.

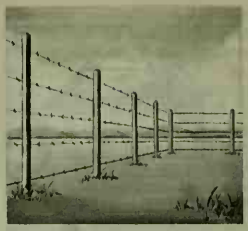

FIG. 14.—EQUAL SPACING

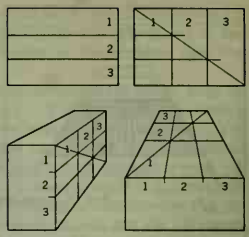

FIG. 15.—SUBDIVISIONS

All three-dimensional units can then be translated into a two-dimensional surface (fig. 12).

This method is called the architect's or office method. It is found to be adaptable to most perspective problems and it is the basis for most perspective projections.

The vanishing point is located by dropping perpendicular lines from the previously located points L and R to the horizon (fig. 13A). The side elevation is placed so that it rests on the ground line. A horizontal line from the top of this elevation to the central line gives the true height of the box. Lines from the top and bottom of this height line extended to the vanishing points will give the near corner of the box in true perspective, with the sides of the box extending to the vanishing points. It is then necessary to find where the sides of the box actually end.

A line is drawn from the station point to the right-hand corner of the plan. It intersects the picture plane at a point indicated by the arrow (fig. 13B). A line is drawn to the left corner in the same manner. The space between the two arrows measures the extent of the box as it would be seen on the picture plane. Perpendicular lines from these arrows drawn downward through the sides of the box cut the sides off at the correct place. The perspective picture is completed by drawing lines to the vanishing points from the established corners of the box.

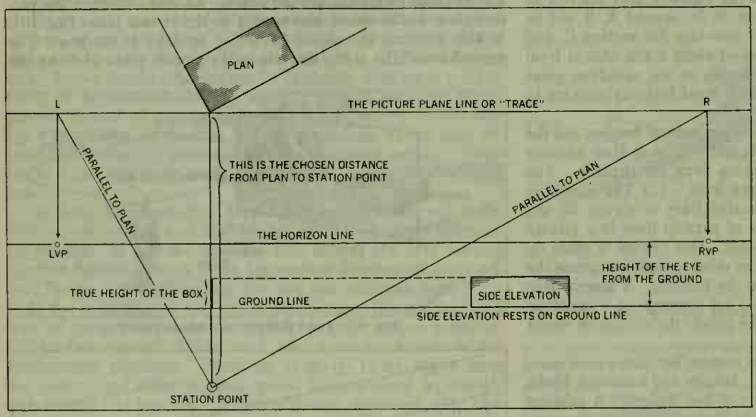

FIG. 12.—COMPLETE PERSPECTIVE ARRANGEMENT

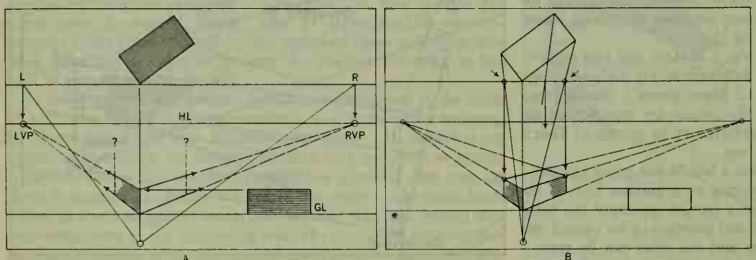

FIG. 13.—PERSPECTIVE PROJECTION

Division of Space.—If a line divided into equal parts is drawn in perspective, the parts become smaller as they recede (fig. 14). The simplest division is two equal parts. A square, rectangle or line may be divided into halves by the use of intersecting diagonals.

The point of intersection becomes the central point and a line drawn through this point parallel to the sides is the line of division. When the rectangle is drawn in perspective this method of dividing still holds true; the true centre is the point where the diagonals intersect.

These divisions in turn may be subdivided into quarters and then into eighths and sixteenths, if desired.

When the space cannot conveniently be subdivided into halves, another method may be used. To divide a rectangle into three equal parts with vertical lines (fig. 15), it should be first divided by length lines into three parts. A diagonal is then drawn. If the vertical lines are drawn where the diagonal intersects the length lines the correct spacing is obtained.

Fig. 16 is an example of a facade with seven columns drawn in perspective. Irregular divisions also can be projected in the same manner. These methods follow the principle of dividing measurable lines (*i.e.*, lines parallel to the picture plane) and of translating these measurements into corresponding divisions on the receding perspective line.

There is another method of subdivision in perspective in which a high or low vanishing point is used. It can be understood by

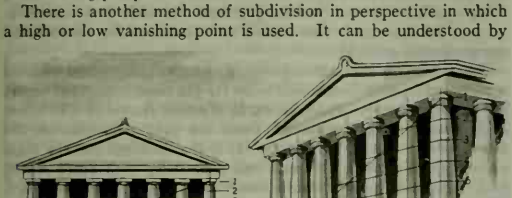

FIG. 16.—FACADE IN PERSPECTIVE

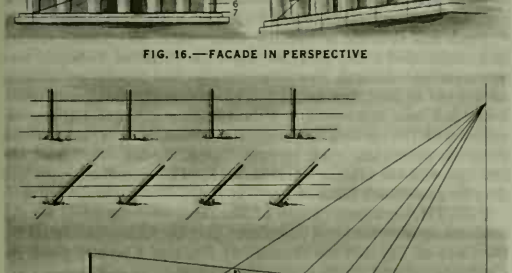

FIG. 17.—CONTINUOUS SPACING

drawing a fence in which all the posts lean at the same angle along the line of the fence (fig. 17). The posts will be parallel to one another and will all point to a vanishing point in the sky (or below the horizon if leaning in the opposite direction). This point will be somewhere directly above (or below) the vanishing point of the fence. To verify this, tilt the posts more and more until they finally lie end to end on the ground. It will be found that their vanishing point has moved down in a perpendicular line until it is the same as the vanishing point of the original fence. Using the draftsman terminology, this perpendicular line on which the vanishing points fall is the vanishing trace of the vertical plane of the fence. An axiom applied to this form of projection is that parallel lines in a plane have their vanishing points in the vanishing trace of the plane.

If the diagonal drawn between the first two posts is extended to intersect the vanishing trace, the successive posts can be located by the use of this point of intersection as the common vanishing point of all the diagonals.

Three-Point Perspective.—This system incorporates in addition to the two horizontal vanishing points a third vanishing point to which all vertical planes relate. It is of limited use.

PERSPIRATION. Perspiration is an inclusive term referring to any water, either in vapour or visible form, which is given off by the normal skin. There are two sources: the epidermis and the sweat glands. The average adult loses about 500 g. of water vapour via the transepidermal route every 24 hours. This type of water loss is called insensible perspiration and involves no chemicals besides water. The mechanism of loss is obscure, but it would appear that the water loss, which is constant, is associated with the growth and aging process of the epidermal cells as they form keratin. Only factors affecting the epidermal cells have an influence on the rate of epidermal water loss.

The common usage of the word perspiration disregards the above vapour loss and relates it solely to the secretion from the eccrine sweat glands. These glands are distributed over the entire skin surface of man. Totaling approximately 2,000,000 in number, they show marked regional differences in density. The palm and sole may present over 2,500 per square inch, whereas the back may have fewer than 500 per square inch. Each gland is a simple coiled tubular unit. The secretory coil is deep in the dermis and from it the sweat duct extends up through the dermis and epidermis.

The sweat pore is not visible except on the palms and soles. The glands provide surface water for evaporative cooling of the body under heat stress, 540 cal. being lost per litre of sweat evaporated. In cool environments the glands remain entirely at rest.

However, once the skin temperature or body temperature becomes elevated, many of the glands are instantly stimulated to secrete. This stimulation is caused by autonomic nerves which are under control of the thermoregulatory centre of the hypothalamus of the brain. In areas which have been denervated (*e.g.*, by sympathectomy, or by neural changes in leprosy) sweating does not take place. The total sweat rate may range from zero to 2,000 g. per hour. Often sweating rates are excessive since only the sweat which evaporates cools the body. Eccrine sweat is about 99% water, the chief solute being sodium chloride. The more efficiently the gland functions, the lower the salt content is. Very little salt is present in the sweat of acclimatized persons, so that a normal person rarely needs salt supplementation of his normal diet despite high sweating rates. Similarly vitamin supplementation is unnecessary since only trace amounts are lost. Eccrine sweating of the palms, soles and to a certain extent elsewhere is under a different neural control, reflecting emotional tension rather than thermal stress; *e.g.*, the cold sweat of shock or motion sickness.

Closure of the sweat pores with subsequent extravasation of trapped sweat into the skin is the cause of prickly heat, a common summer ailment.

Apocrine sweat is a second type formed in human skin. It arises from apocrine sweat glands, most of which are in the armpits and appear at puberty as an offshoot of the hair follicles. Very small amounts of sweat are continuously formed and stored in these glands, later to be expelled in response to emotional rather than thermal stimuli. The expulsive force is provided by a sheath of muscular tissue enveloping the glands. Apocrine sweat is a whitish odourless liquid which contains considerably more solid material than eccrine sweat. Surface bacteria of the skin act on the lipid content of this sweat to form odorous unsaturated fatty acids, thus accounting for the distinctive "underarm odour." In rare instances apocrine sweat may contain unusually large quantities of pigment, a condition called chromidrosis. Such reddish-brown sweat is normally produced by the apocrine sweat glands of the hippopotamus. *See* also ANIMAL HEAT; SKIN: *Cutaneous Appendages.* (W. B. SY.)

PERTH, EARLS AND DUKES OF. The Scottish title of earl of Perth was bestowed upon JAMES DRUMMOND (*c.* 1580–

1611), 4th Baron Drummond, in 1605. James was succeeded by his brother JOHN (*c.* 1584–1662), who in the Civil War was appointed commissioner of war in Perthshire for the parliament. His second but first surviving son JAMES (*c.* 1615–75), 3rd earl of Perth, also served the parliament, but later fought with the marquess of Montrose at Philiphaugh (Sept. 13, 1645) and was taken prisoner. His second but first surviving son JAMES (1648–1716) declared himself a Catholic on the accession of James II (James VII of Scotland) and during his reign largely controlled affairs in Scotland. Imprisoned (1688–93) after the revolution of 1688, in 1696 he joined the exiled king, who in March 1690 had created him (titular) duke of Perth. He was governor to Prince James (the Old Pretender) from 1696 to 1706. His son JAMES (*c.* 1673–1720), 2nd titular duke and 5th earl of Perth, was several times imprisoned and commanded the Jacobite cavalry at the battle of Sheriffmuir (Nov. 13, 1715). Attainted in 1716, he escaped to France. His son JAMES (1713–46) joined Charles Edward (the Young Pretender) in 1745, fought with him at Prestonpans, Carlisle, Stirling and Culloden, and at Derby was the only counselor to advise against a return to Scotland. After the battle of Culloden he also was attainted (1746), escaped, but died at sea. Unmarried, he was succeeded by his brother JOHN (1714–47), 4th titular duke and 7th earl, who fought at Falkirk and Culloden, escaped to France and fought for the French in the Austrian Succession War. He was succeeded by his uncle of the half-blood, JOHN (1679–1757), a son of the 1st titular duke by his second wife. John's successor, EDWARD (1690–1760), was his half brother, son of the 1st duke by a third wife. He served as a general in the French cavalry. On his death without issue the titular dukedom became extinct.

The representation of the earldom passed to Edward's cousin JAMES LUNDIN, afterward DRUMMOND (1707–81), grandson of John, 1st titular duke of Melfort (a brother of the 1st titular duke of Perth) by his first wife, Sophia, heiress of Lundin. To his third but only surviving son JAMES (1744–July 1800) the family estates were restored in 1785, and in 1797 he was created Lord Perth, Baron Drummond of Stobhall, County Perthshire, in the peerage of Great Britain. On his death without male issue, the United Kingdom peerages became extinct and the representation of the earldom passed in turn to his cousins JAMES LOUIS DRUMMOND (1750–Sept. 1800) and CHARLES EDWARD DRUMMOND (1752–1840), respectively 4th and 5th titular dukes of Melfort, great-grandsons of the 1st duke by his second wife. Both died without issue and their nephew GEORGE (1807–1902) succeeded to their claims. In his time the attainders of 1716 and 1746 were reversed and in 1853 he was declared entitled to various Scottish dignities, including the earldoms of Perth and Melfort.

George was predeceased by both his son and his grandson and on his death the earldom of Melfort became extinct or dormant and the earldom of Perth passed to his kinsman, WILLIAM HUNTLY DRUMMOND (1871–1937), who in 1893 had succeeded his father as 11th Viscount Strathallan. His half brother and successor, JAMES ERIC (1876–1951) was private secretary to the prime minister Herbert Asquith (1912–15) and to the foreign secretaries Sir Edward Grey (1915–16) and A. J. Balfour (1916–19). Known as Sir Eric Drummond (from 1916), he accompanied Balfour to the U.S. in 1917 and to the Paris peace conference, and he became secretary general (1919–33) of the League of Nations. He was ambassador in Rome (1933–39) and in 1946 became deputy leader of the Liberal peers. His son, JOHN DAVID DRUMMOND (1907–) is 17th earl of Perth and 13th Viscount Strathallan.

PERTH, the capital of Western Australia, is situated in the southwest of the state on ground rising 200 ft. (61 m.) from the right bank of the Swan river about 12 mi. (19 km.) N.E. of its mouth, which forms the inner harbour of Fremantle (*q.v.*). Pop. (1961) 94,508; metropolitan area (including Fremantle) 420,133, more than half the population of the state. The climate is of the Mediterranean type with mean monthly temperatures ranging from 23.5° C. (74° F.) in February to 13° C. (55° F.) in July, an average daily sunshine of 7.8 hr. and an average annual rainfall of 36 in. (914 mm.), falling mainly from May to October.

Though some of the streets are still narrow, the city has been largely rebuilt in the 20th century and the suburbs stretch for more than 20 mi. (32 km.) along the northern side of the river. Development of the southern side was stimulated by the opening of a new causeway over the Swan across Herisson Island in 1952 and subsequently by the building of a bridge at the narrows at the western end of Perth water. Perth contains some of the finest buildings, avenues and streets (*e.g.,* St. George's terrace) in Australia. The public buildings include an Anglican and a Roman Catholic cathedral, government house, parliament house, an observatory (1896) and the University of Western Australia (founded 1911), with its impressive Spanish-style architecture. There are many state and private schools, a technical college, two teacher-training colleges and a number of private colleges. Perth has about 6,000 ac. (2,428 ha.) of parks and gardens, including King's park (1,000 ac. [405 ha.] of bush set aside as a nature reserve), Belmont park (the state's main horse-racing centre) and the zoological gardens.

Besides being the state's political, administrative and judicial centre, Perth, with Fremantle, is by far the most important centre for trade, commerce and banking in Western Australia. It is not highly industrialized, although there are light industries on the outskirts and around Fremantle. It is the terminus for the main railway routes within the state and connecting with other states, and there is a modern international airport at South Guildford. Most of the public utilities are administered by the state government. The water supply is obtained from catchments in the Darling range, supplemented by artesian wells in summer.

Perth was founded in 1829 by Capt. (later Sir) James Stirling and constituted a city in 1856, when the Anglican bishopric was also created. Growth was slow initially, the population totaling only 8,447 in 1891, but in the preceding year the Coolgardie goldfields had been discovered and the resulting influx of settlers, together with the opening of Fremantle harbour in 1897, led to rapid progress, subsequently encouraged further by the opening of the rail link with the eastern states in 1917. The Commonwealth and Empire games took place in Perth in 1962.

PERTH, an inland county of Scotland, bounded north by the counties of Inverness and Aberdeen; east by Angus; southeast by the Firth of Tay and the counties of Fife and Kinross; south by Clackmannan and Stirling; southwest by Stirling and Dunbarton; west by Argyll; and northwest by Inverness. It is the fourth largest county in Scotland, its land area being 2,493.4 sq.mi. (6,458 sq.km.). It has a compact, roughly circular shape. The Highland boundary fault runs with the Caledonian trend northeast-southwest from near Alyth to near Aberfoyle, and is a rough boundary between lowland Perth, the southeastern third of the county, and the remaining two-thirds lying in the south-central Grampians.

Physical Features.—Highland Perth, a plateau planed across rocks metamorphosed by Caledonian folding and overthrusts, mainly Dalradian mica schists, limestones, and quartzites, is much dissected so that many summits and ridges are at about 3,000 ft. (914 m.), with higher residual heights in various rocks: Ben More, 3,843 ft. (1,171 m.) east of Crianlarich, in schists; Ben Lawers, 3,984 ft. (1,214 m.); and Schiehallion, 3,547 ft. (1,081 m.), near Loch Tay, in quartzites. Many conical hills along the Highland edge are in a belt of quartzite: Ben Venue, 2,393 ft. (729 m.), and Ben Ledi, 2,873 ft. (876 m.), in the Trossachs; Ben Vorlich, 3,224 ft. (983 m.), and Ben Chonzie, 3,048 ft. (929 m.), near Loch Earn, and others stretching northeast to the county boundary. Dissection is in blocks, valleys tending to trend east (Forth, Loch Earn, Loch Rannoch), northeast or southwest (central and Loch Tay, Glen Tilt), and southeast (Garry-Tummel-Tay, the dominant river system of Perth). Southwestern Perth was part of the great southwest Highland centre of ice dispersal during the maximum glaciation. Corrie glaciation, rock-basin lakes (Lochs Earn, Tay, Katrine, etc.), and ice-molded valleys are all common, as well as ice marginal and other moraines.

Vegetation varies from the well-studied Alpine flora of Ben Lawers and other peaks, through acid grassland (fescue–purple moor grass–bent grass–heather), which dominates in the centre and west of the county, to heather–blaeberry in the drier east and

northeast with rare survivals of the Scots pine forest association as in Black Moor of Rannoch, and residual birch and oak woods in the valleys. There are many well-wooded estates, largely artificial planting as near Blair Atholl and in the Trossachs. Wildlife includes red deer and wildcat, golden eagle, dotterel, ptarmigan, grouse, black grouse, and capercaillie.

Rainfall varies between 60 to 100 in. (1,524 to 2,540 mm.) in the southwest of Highland Perth, and 40 to 50 in. (1,016 to 1,270 mm.) in the northeast. May is the driest month but the summer months tend to be reasonably dry and sunny, particularly in the east of the area. Temperatures are naturally extremely variable.

Lowland Perth is by no means a flat plain. Hills fringing the Highlands and in the Ochils and Sidlaws represent dissected plateaus of 1,500–2,000 ft. (457–610 m.); between these uplands Strathmore, Strathallan, and the Forth Plain make up a complex lowland corridor running northeast-southwest, with surfaces of 100–500 ft. (31–152 m.), and also at about 750 ft. (229 m.) fringing and linking the hills, all cut mainly across Old Red Sandstones. On the low ground drumlins and other boulder clay deposits are dominant at the surface; in these, Highland rocks and Old Red Sandstone rocks are ground and intermixed to give the basis of a fertile, workable soil, given drainage. Some fluvioglacial sands and gravels give lighter soils, including the famous fruit-growing tracts of Strathmore and the Carse of Gowrie. Fringing the Firth of Tay are fertile heavy clays in the carse lands, and again in the Carse of Stirling, acid grasslands dominate the hills, while the lower land presents a landscape of large farmsteads among the big square fields varied by pleasant woodlands and estate parks.

The Queen Elizabeth Forest Park, created in 1953, extends for 42,000 ac. (16,997 ha.) in the counties of Perth and Stirling and includes Loch Ard forest (34,295 ac. [13,879 ha.] in both counties) and Rowardennan (in Stirling). It stretches from Loch Lomond to the fringe of the Trossachs and has 24,000 ac. (9,713 ha.) of forest land and 18,000 ac. (7,285 ha.) of moor and mountain. The Forestry Commission also controls (1962) 17 forests covering 108,757 ac. (44,014 ha.) in Perth, and 4 forests covering 16,662 ac. (6,743 ha.) that overlap into neighbouring counties. Rannoch Forest, the biggest (45,617 ac. [18,461 ha.]), is south of Loch Rannoch where is the Black Wood of Rannoch, remains of the ancient Caledonian Forest. There is a training school for foresters at Pitlochry. Part of the Moor of Rannoch is a national nature reserve (3,704 ac. [1,499 ha.]).

Mean annual rainfall in the Lowlands is below 30 in. (762 mm.) in parts of Strathmore, but 30 to 35 in. (762 to 889 mm.) is a typical figure for low-lying areas, with 40 to 60 in. (1,016 to 1,524 mm.) in the hills. Spring and early summer tend to be dry and sunny, but summer and autumn are usually sunny enough for holiday and harvest. Mean monthly temperatures in a typical low-lying station vary from about 3° C (37° F) in January to 14° C (57° F) in July. (A. T. A. L.)

History.—In A.D. 83 the Roman general Gnaeus Julius Agricola explored the lands beyond the Forth and in the following year penetrated to the Grampians. The growing lawlessness of the southern Picts and their frequent raids in the more settled country in the south, later compelled the attention of the Roman emperor Severus. But though he led a strong army to the shores of the Moray Firth, he was unable effectually to subdue the tribesmen. There were several Roman forts in the county such as those at Bochastle, Dalginross, Bertha, Fendoch, and Gourdie, as well as a legionary fortress at Inchtuthil; along the Earn there were many signal stations.

When the Romans finally withdrew from Britain, the Picts established their capital first at Abernethy and then at Forteviot. Abernethy was the centre of the Celtic Church after the conversion of the natives by St. Ninian. Palladius (deacon of the Roman Church), and other missionaries in the 5th and 6th centuries. On the burning of Forteviot by the Norsemen in the 8th century, the seat of Pictish government was removed to Scone. In the latter half of the 9th century, Dunkeld—to which Kenneth I, MacAlpin had brought some of the relics of St. Columba from Iona—became the scene of monastic activity.

The Danes periodically harried the land, but suffered a crushing defeat at Luncarty in 961. In 1054 Macbeth was defeated at Dunsinane by Siward, earl of Northumbria, who had invaded Scotland in the interest of his kinsman, Duncan's son, who, on the death of the usurper three years later, ascended the throne as Malcolm III. With Malcolm's accession the Celtic rule of the monarch of Scone came to an end. The royal burgh of Perth (*q.v.*) became the capital of Scotland at the beginning of the 12th century and remained the capital until 1452; from that time the history of the county is merged in that of the county town, with the exception of such isolated incidents as the removal of the coronation stone from Scone to Westminster in 1296, the defeat of Robert I, "The Bruce," at Methven in 1306, the Battle of Dupplin (*q.v.*) in 1332, the victory of Viscount Dundee (John Graham of Claverhouse) at Killiecrankie in 1689 and the indecisive contest at Sheriffmuir in 1715.

Doune Castle, belonging to Thomas Randolph, earl of Moray, was built in the 14th century and was a royal palace. It was restored in 1883. Blair Castle, home of the duke of Atholl, is in Scottish baronial style, with a 13th-century tower.

Among non-Roman archaeological remains are the hill fort on Dunsinane; the ship barrow of the Vikings at Rattray; weems (or earth houses) in the parishes of Monzie, Alyth, and Bendochy; standing stones near Pitlochry; and an extraordinary assemblage of sculptured stones in the museum at Meigle.

Population and Administration.—The population in 1961 was 127,056. Gaelic and English were spoken by 1,686 persons and one spoke Gaelic only. The city and royal burgh of Perth (41,196) is the only large burgh. There are 11 small burghs: Aberfeldy (1,469), Abernethy (601), Alyth (1,862), Auchterarder (royal burgh, 2,425), Blairgowrie and Rattray (5,181), Callander (1,655), Coupar Angus (2,048), Crieff (5,771), Doune (786), Dunblane (2,923), and Pitlochry (2,501). There are five county districts.

With Angus the county forms the sheriffdom of Perth and Angus, with a sheriff substitute presiding at Perth and Dunblane. For parliamentary purposes it is divided into the Perth and Western divisions (the latter including Kinross), each returning one member. There are secondary schools at Perth, Crieff, Blairgowrie, Aberfeldy, and Callander. Trinity College, in Glenalmond, and Strathallan are well-known boys' schools.

The Economy.—The arable land is chiefly in the drier regions of the east and southeast, the soil for the most part being fertile. The best heavy carse land is rich, and produces heavy crops of wheat, potatoes, sugar beet, beans, timothy, and silage crops. The principal cereal crops are oats, barley, and wheat. The county exports a big tonnage of seed potatoes and grows considerable quantities of turnips, swedes, and sugar beet. The growing of small fruit is a speciality, and Perth is the main raspberry growing county in Scotland.

There are many herds of pedigree livestock, particularly of the Shorthorn and Aberdeen Angus beef breeds. On the hills Blackface sheep are carried, and on many of the foothill farms herds of breeding beef cows are established.

The rivers and lochs abound with good salmon and trout; Tay salmon is especially famous. Hardly any of the streams have suffered pollution from industries.

Perth has valuable waterpower resources which have been developed by the North of Scotland Hydro-Electric Board. In the Tummel Valley is the greatest hydroelectric power development in Scotland. The Tummel and its tributaries, which drain an area of 710 sq.mi., are harnessed in ten power stations with an installed capacity of 250 megawatts and an average annual production of 650,000,000 units (kw-hr.) of electricity. Further development was planned at Loch Laidon in the Moor of Rannoch. The Breadalbane scheme in the mountainous area between Glen Lyon and Loch Earn comprises eight power stations served by a catchment of 202 sq.mi. The total capacity of the stations is 118 megawatts and their annual output is about 390,000,000 units (kw-hr.) of electricity. The control centre for the board's stations is situated near Pitlochry.

Dyeing and finishing works are in Perth and its vicinity. Flax and jute mills are at Blairgowrie and Rattray and cotton mills at Stanley, Deanston, and Perth. Woolens, linen, jute, and tartans

are woven at Dunblane, Alyth, Auchterarder, Aberfeldy, and Pitlochry. Whisky is distilled at Pitlochry, Aberfeldy, and Blackford, while Perth is a centre for blending and bottling.

Tourism is becoming increasingly important to Perth, with its favourable central position. Outdoor recreation is gaining in popularity, particularly winter sports (in the north), pony trekking and water skiing (in which the national championships are held on Loch Earn). Dinghy sailing is also popular on several lochs.

(A. L. BL.)

PERTH, a city, royal and large burgh and county town of Perth, Scot., about 22 mi. (35 km.) W.S.W. of Dundee by road. Pop. (1961) 41,196. Area 6.1 sq.mi. (15.8 sq.km.). It is on the right bank of the Tay, between the meadows of the North Inch and those of the South Inch, both laid out as public parks. On the left bank of the river (crossed by three bridges) Kinnoull hill rises 729 ft. (222 m.). The Perth bridge, which crosses the Tay just below North Inch, has nine arches and was built by John Smeaton in 1766–71. The city has long been famous for its dye works. Other industries include whisky blending, the making of glassware (and particularly of gauge glasses), jute, carpet and linen manufacture. Perth is the centre of a prosperous agricultural area, with sales which attract buyers from all parts of the world.

Notwithstanding the importance of Perth in former times (it was the capital of Scotland until *c.* 1452), almost the sole relic of the past is the church of St. John the Baptist. The original building is believed to have been erected in the time of Columba, but the present choir was built *c.* 1440 and the nave *c.* 1490. In 1598 the church was divided into two churches and a third was inserted between them in the 18th century, but under Sir Robert Lorimer the whole was restored to its original form as a World War I memorial (1925–28). There, in 1559, John Knox preached his famous sermon in denunciation of idolatry, as a result of which the Dominican, Carthusian, Franciscan and Carmelite friaries were destroyed. The castle, palace and fortress have also disappeared. The tombstone of James I and his queen, who, though the king was murdered in the Dominican, were buried in the Carthusian monastery (destroyed in 1559), was afterward removed to St. John's church.

During the period between the beginning of the 12th century and the reign of James II many of the Scottish parliaments were held in a building (demolished in 1818) where the Freemasons' hall now stands. The supposed house of Catherine Glover, the "Fair Maid of Perth," still stands in Curfew Row. James VI's hospital, founded in 1569 on the site of the Carthusian monastery, was converted into workmen's dwellings. A 19th-century replica of the Mercat (market) cross, which in 1668 replaced one destroyed by Oliver Cromwell, stands opposite the city hall.

Public buildings include St. Ninian's Episcopal cathedral (1850–90); the city chambers; the county buildings (1808–20); the art gallery and museum (1935), which incorporates as its principal feature the Marshall memorial (1824) and contains the museum of the Black Watch, the collections of the Literary and Antiquarian society and the Perthshire natural history museum; and the Sandeman public library, founded by a bequest of Professor Sandeman of Owens college, Manchester. The general (convict) prison for Scotland was originally erected in 1812 as a depot for French prisoners.

Northwest of the city are the military barracks (1793–94). The burgh grammar school, supposed to date from the 12th century, was amalgamated with the Perth academy (1807) and Sharp's institute (1860).

History.—During the time that it was occupied by the Romans, a period estimated at 320 years, the city was called Victoria; its present name probably derives from the Celtic Abertha ("at the mouth of the Tay"). On the conversion of the original Pictish inhabitants and the dedication of the first church to St. John the Baptist, the town was designated St. Johnstoun, and it continued to be known indifferently by this name and that of Perth down to the 17th century. Perth is stated to have been a burgh in 1106 and was made a royal burgh by William the Lion in 1210.

During the Scottish Wars of Independence its fortifications were strengthened by Edward I (1298). Robert the Bruce several times ineffectually attempted to seize it, but in 1311 he succeeded in scaling the walls during a night attack. This was the fourth and most brilliant of the seven sieges which the city sustained. Taken by Edward III in 1335, it was recaptured in 1339. In 1396 the combat between the Clan Chattan and the Clan Quhele, described in Sir Walter Scott's *Fair Maid of Perth*, took place on the North Inch in the presence of Robert III and his queen, Annabella Drummond.

The Dominican friary (Blackfriars) was the scene of the murder of James I by Sir Robert Graham, instigated by Walter, earl of Atholl, in 1437. In consequence Perth lost its status as capital, in which it had succeeded to Scone, and the parliament courts were transferred to Edinburgh in 1482.

Gowrie house (on the site now occupied by the county buildings) was the scene of the mysterious "Gowrie conspiracy" against James VI in 1600. The town was taken by the marquess of Montrose in 1644, by Cromwell in 1651, and was occupied by Viscount Dundee, John Graham of Claverhouse, in 1689.

In 1715 the Old Pretender was proclaimed king at the Mercat cross, and the chevalier himself appeared in the city in the following January, only to leave it precipitately on the approach of the earl of Argyll.

PERTH AMBOY, a city in Middlesex county, N.J., U.S., at the mouth of the Raritan river, on Raritan bay and Staten Island sound, 29 mi. (47 km.) S.W. of New York city.

It is strategically located on the fringe of the two major metropolitan areas of the east, Philadelphia and New York. Connecting these areas with the city are an elaborate highway system, four rail lines and a harbour for ocean-going ships.

Local industry is well diversified and produces steel, nonferrous metals, petroleum products, building materials, chemicals, paints, lead, printing and electrical goods, clothing, food products and cigars.

Despite its industrialization the city stresses residential living and supports numerous parks and recreation and play areas. Public utilities (electricity and water) are municipally owned.

Perth Amboy was settled in the late 17th century and from 1684 to 1702 was the capital of the colony of East Jersey. The original name, Amboy, is of Indian origin. Later Perth was added in honour of an early proprietor, the earl of Perth. A city charter, one of the first in New Jersey, was granted in 1718. The last royal governor of the colony, Benjamin Franklin's son William, resided in the city in the governor's house (Westminster house, erected in 1764), which is one of a number of colonial buildings still standing.

The city was occupied by the British in 1776–77 and later evacuated when Gen. George Washington's troops seized northern New Jersey.

For comparative population figures *see* table in NEW JERSEY: *Population.* (W. L. CA.)

PERTINAX, PUBLIUS HELVIUS, Roman emperor Jan.–March 193, was born in Liguria on Aug. 1, 126, the son of a freed slave. After teaching in a school, he entered the army, commanding units in Syria and Britain, on the Danube and Rhine before earning distinction in the great German invasion of 169. Given senatorial rank to command a legion, he was promoted to the consular commands of Moesia, Dacia and Syria, but under Commodus fell from favour, together with the future emperor Septimius Severus, during the ascendancy of Perennis. Recalled about 186 to command the mutinous army of Britain, he was withdrawn at his own request, but in the last years of Commodus became prefect of the city of Rome, while Severus commanded the upper Danube armies.

When Commodus was murdered on Dec. 31, 192, the senate met before dawn and proclaimed Pertinax, then the senior marshal of the empire, before the praetorian guards awoke. He endeavoured

to enforce unpopular economies in both civilian and military expenditure, and was murdered by a small group of undisciplined soldiers on March 28, 193. When Severus became emperor later in the year he decreed divine honours for him and took the name Pertinax.

PERTZ, GEORG HEINRICH (1795–1876), German historian, the first general editor of the *Monumenta Germaniae historica* for which he laid down the determining principles. Pertz was born in Hanover, March 28, 1795, and was a pupil of A. H. L. Heeren at Göttingen. In 1823 he became secretary of the archives in Hanover, in 1827 royal archivist and in 1842 chief librarian in Berlin. In 1832 Pertz founded the *Hannoverische Zeitung* to promote Baron von Stein's ideas; he also sat in the Hanoverian second chamber. His enduring work, however, was done on the *Monumenta Germaniae*. This owed its inception to Stein but behind it lay a scholarly need, a new pride in the German past and a romantic interest in the middle ages. In 1819 the work was begun under the auspices of the newly founded Gesellschaft für ältere deutsche Geschichtskunde, supported by funds from both Prussia and Austria. Stein invited Pertz to help in 1819 and he journeyed through Europe examining manuscripts and making many finds. In 1823 Stein entrusted him with the general direction of the work, which was to be a critical edition of writings on German affairs (*Scriptores, Leges, Diplomata, Epistolae* and *Antiquitates*) from *c.* 500–1500. The first two volumes (Carolingian narrative sources), largely Pertz's work, came out in 1826 and 1829 and by 1873, when he was superseded, more than 20 volumes had appeared. Pertz also wrote a life of Stein (6 vol., 1849–55) but his gift was for research rather than for creative work and his biographies had less merit than his editions. He died in Munich, Oct. 7, 1876.

BIBLIOGRAPHY.—Pertz's letters to T. v. Schön and J. G. Droysen, ed. by F. Rühl (1896); his *Autobiography* (in Eng., ed. by his wife; n.d.); H. Bertzlau, *Geschichte der Monumenta Germaniae Historia* (1921).

PERU, a republic on the western side of South America. Its area is estimated officially to be 496,222 sq.mi. (1,285,215 sq.km.) which makes it the third largest South American country, following Brazil and Argentina. Along the Pacific ocean it extends in a general southeasterly direction from 3° 16′ S. to 18° 21′ S., with a seacoast of about 1,400 mi., but east of the Andes it reaches north to the equator. Peruvian territory borders on Ecuador and Colombia on the north, Brazil and Bolivia on the east and Chile on the south. Often in the past the territorial interests of these neighbouring countries conflicted with those of Peru, and lengthy negotiations resulted. Indistinctly defined boundaries were of little importance so long as all the territories involved had colonial status. The establishment of sovereign states, however, changed the situation fundamentally. Such factors as contradictory royal decrees, as well as the lack of accurate geographic knowledge of the areas concerned and the later economic development of certain previously unimportant frontier zones, combined to make the problem of modern boundary delimitation a complex one indeed. The frontier between Spanish and Portuguese interests along the upper Amazon, determined by the treaty of San Ildefonso in 1777, was revised by a treaty between Peru and Brazil in 1851 and further modified in 1909 by a treaty which involved Bolivia in addition to Peru and Brazil. While Peru has settled most of its frontier problems with Brazil amicably, violence has marked the boundary disputes with its Spanish-speaking neighbours, culminating in open warfare in the case of Chile and Ecuador.

The more-than-a-century-old frontier dispute with Ecuador was terminated in 1942 by a settlement on the whole favourable to Peru. In the west it retained the areas around Tumbes and Jaén which Ecuador had claimed, while in the east it was confirmed in its rights of possession to those parts of Ecuador's former claim containing navigable affluents of the Marañón and the Amazon. Despite the official settlement, however, the frontier zone remains a potential trouble spot, while Ecuador continues to clamour for access to the important waterways. In the north Peru's common boundary with Colombia follows the Putumayo river to the edge of the Leticia Trapezium, Colombia's southernmost extension, and around it to the south and east to the confluence of the Yavari (Javari) and the Amazon. The boundary then leads up the Yavari to its source, south along the water parting between the Ucayali and the Yurúa, and then irregularly to the southeast to the confluence of the Heath and the Madre de Dios. It ascends the Heath in a southerly direction to its source, continuing by an irregular line to the shore of Lake Titicaca, crossing the lake in a southeasterly direction to the Desaguadero, and thence southwest to Chile's northernmost point at 17° 30′ S. The boundary with Chile, after 46 years of bitter dispute, was finally settled in 1929, largely through the mediation of the United States. The line was drawn from the Pacific to the Bolivian border parallel to and 10 km. (6 mi.) N. of the Arica-La Paz railway.

I. PHYSICAL GEOGRAPHY

Peru is sharply divided into three major natural regions: the Pacific coastal desert, the Andes mountains and the montaña, or eastern forested area. The coastal desert and the mountains are made up of folded and faulted geologic structures of great complexity. Though only south of latitude 14° S. does one find recent volcanic activity, the whole coastal and highland area is one of frequent earthquakes resulting from the continuing process of mountain building. Inland from the capital city of Lima the highlands are about 130 mi. (210 km.) wide, but in southern Peru they increase to about 300 mi. (480 km.) wide. There are many summits that stand more than 20,000 ft. (6,100 m.) above sea level, while off the Peruvian coast the ocean bottom is more than 20,000 ft. below sea level. The coast is one of the world's very dry regions; however the eastern plains, as well as the east-facing slopes of the mountains, receive abundant rain.

1. Geology and Surface Features.—Throughout most of the Peruvian highlands three surface elements make up the mountain landscape. These are a high-level surface of gentle slopes; clusters and ranges of high peaks standing above this surface; and profound canyons cut below the high surface.

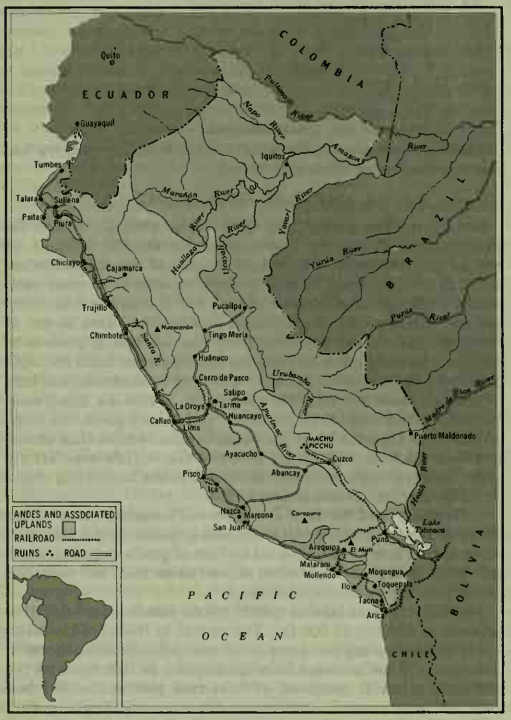
The high-level surface of gentle slopes stands at an elevation between 10,000 and 15,000 ft. The valleys in this area are broad and the streams sluggish. Long-continued denudation has stripped the cover of loose material from the hillsides so that much of the highland surface is composed of bare rock and waste-filled hollows.

The second surface element includes the clusters and ranges of

high peaks that stand upon the high-level surface as on a platform. The highest summits are between 18,000 and somewhat more than 20,000 ft. above sea level. During the Ice Age, glaciers formed at these high altitudes and produced the landforms characteristic of glaciated mountains: horns, cols, cirques, troughs, moraines and glacial lakes. Nineteenth-century writers described the highlands as made up of three or four parallel cordilleras which were joined together at a few places by mountain knots. This description is essentially incorrect. Actually the high ranges that rise from the high-level surface are short and discontinuous. They are oriented in different directions, some at right angles to the general trend of the highlands. Only the westernmost range, which forms the continental divide, is more or less unbroken, except in northern Peru. Along the southwestern side of the highlands, south of latitude 14° S., volcanic forms appear. There are numerous volcanic cones and lava flows. The best known of the volcanoes is El Misti, the cone-shaped mountain that overlooks the city of Arequipa.

The third major surface element includes the deep canyons that have been cut into the high-level surface. Often at the heads of these canyons are shallow intermontane basins, perhaps a few hundred to more than a thousand feet below the surface. These basins are of special importance because they are at a low enough altitude so that crops can be grown in them to support concentrations of farmers. Below the basins the rivers enter narrow canyons and plunge from elevations above 10,000 ft. to elevations below 6,000 ft. in relatively short distances. The great canyons, such as that of the Marañón, are so large that they cannot be viewed as a whole. Scenery, such as that presented by the Grand canyon of the Colorado river in Arizona, is encountered in few places in the Andes because all the Andean surface features are on such a vast scale. Along the canyon bottoms there are only isolated patches of level flood plain.

The highest peaks and the largest areas of high-level surface are found in southern and central Peru. Along the southern border, the high-level surface is about 15,000 ft. above sea level, and the Titicaca basin is below 13,000 ft. The surface of Lake Titicaca (*q.v.*) is 12,497 ft. (3,809 m.) above sea level. Several major streams, such as the Urubamba and the Apurímac, rise in the rugged mountain cluster known as the Nudo de Vilcanota, located just northwest of the Titicaca basin. Another extensive high area is north of Lima, where the Nudo de Pasco forms the headwaters of the Huallaga and the Marañón. A short distance to the west, the towering wall of the Cordillera Blanco overlooks the valley of the Santa river. Toward the north the elevation of the highest peaks decreases, and less and less of the high-level surface remains undissected. Along the border between Peru and Ecuador, the high-level surface entirely disappears, and there is only a complex pattern of ridges and V-shaped valleys. In this region it is possible to cross the mountains from the eastern plains to the west coast with a climb of only about 7,000 ft., but the slopes are so steep that no route of passage has ever been developed.



PHYSICAL FEATURES OF PERU

The greatest amount of dissection is found on the rainy east-facing slopes of the highlands. There the streams have cut a maze of valleys and knifelike ridges, all covered by a dense, wet forest. Along the eastern margin of the mountains the upturned rock strata form parallel cuestas with their steep slopes facing toward the Andes; these cuestas are threaded by a trellis pattern of drainage.

All of eastern Peru is a lowland plain, drained by the meandering headwater tributaries of the Amazon. The surface slopes gently away from the mountains toward Brazil. Where the eastern plains end abruptly against the base of the outermost cuesta the elevation is less than 1,000 ft. above sea level.

2. Climate.—The climatic conditions of the Peruvian coastal desert are unusual. For many years no rain falls; then in one disastrous month heavy rains create havoc in a region normally arid. In normal years, moreover, the coast is cool and damp. From June to October a thick stratus cloud hangs over the parched land, so that the sun is visible only at sunset when it drops below the cloud just before setting. Yet out of the cloud there are seldom more than a few drops of rain. Furthermore, the coastal desert is much cooler than one would expect for the latitude. The average annual temperature at Lima, for example, is 66.7° F. (19.3° C.), whereas that of Salvador in Bahia, Brazil, at the same latitude on the east coast of South America, is 76.6° F. (24.7° C.).

The reason for this cool, cloudy and arid condition is quite simple. Most of the time the prevailing southwest wind comes toward the land across the cold Peru current. The ocean water along the coast averages between 58° and 64° F. (14.4° and 17.8° C.). The air passing over this cold water is chilled. It is stable because cold, heavy air is close to the earth's surface and the warmer and lighter air is aloft. When the air rises against the front of the Andes, it does so sluggishly, forming only a thick stratus cloud (about 2,000 ft. thick). Since the water is coldest at the shore, the air passing over the water is progressively chilled until it forms a sea fog.

But at irregular and unpredictable intervals a sheet of warm water spreads southward over the Peru current. When this happens, the air passing over the water is warmed. The air aloft is then colder and heavier than the air below. This cold, heavy air sinks and the warm, light air is forced to rise. When this air strikes the mountain front, it is forced to rise suddenly and rapidly. Air rising in this way brings great quantities of rain.

In the highlands the climatic conditions are arranged in layers. Average temperatures decrease with increase of altitude. Thus Arequipa, about 8,000 ft. above sea level, has an average annual temperature of 56.8° F. (13.8° C.); Cuzco, at 11,000 ft., has an average of 51.2° F. (10.7° C.); and Vincocaya, about 14,000 ft., has an average of 35.4° F. (1.9° C.). Tropical crops such as sugar cane can be grown up to about 8,000 ft., corn (maize) to about 11,000 ft., wheat to about 12,000 ft. and potatoes to about 14,000 ft. The lower limit of permanent snow in the central Andes is about 16,500 ft., and in southern Peru about 17,000 ft. At the higher altitudes the range of temperature between the warmest and coldest months decreases but the diurnal range between day

BY COURTESY OF UNESCO "COURIER"

PERUVIAN CHILDREN ON A HEIGHT OVERLOOKING THE VALLEY OF THE URUBAMBA RIVER NEAR CUZCO

and night is very great. There sometimes are differences of 40° to 50° F. between the air temperature in the sunny places and air temperature in the shade. In the highlands the rainy season is between October and April.

The rainfall in the highlands decreases toward the south. The great arid zone of South America has its northern limit in Ecuador. From the northern border of Peru, the zone of aridity crosses the Andes diagonally and is east of the mountains south of latitude 30° S. In northern Peru the highlands are well watered and the dry area occurs only on the lower western slopes, but south of Lima the dry zone extends into the western part of the highlands. The heavy rains of the eastern side of Peru invade the highlands in the north, so that the entire border area of Peru and Ecuador except for the coastal region is very rainy. To the south the zone of heavy rains is entirely confined to the east-facing mountain slopes.

The climate of eastern Peru is equatorial. This does not mean, however, that it is correct to describe the montaña as a "steaming jungle." Temperatures are moderately high, averaging 78.3° F. (25.7° C.) for the warmest month in Iquitos, but temperatures as high as 100° F. (37.8° C.) have never been recorded. However, there is never any cool weather, and the region is monotonously warm and humid. The rainfall of eastern Peru is heavy, averaging more than 80 in. per year over much of the montaña.

3. Vegetation.—Reflecting the conditions of the climate, the vegetation of Peru is arranged in a series of north-south belts. Along the Pacific coast the climate is so dry that the land remains entirely barren, and only as one ascends the lower mountain slopes are there scattered xerophytic plants. Where streams come down from the mountains, they support a green strip of vegetation or crops. In the zone where the coastal cloud rests against the slopes of the Andes—between 2,600 ft. and 4,600 ft. E. of Lima—there is a luxuriant growth of quick-flowering plants and grasses during the season from June to October. This is known in Peru as the *loma*.

As rainfall increases on the higher slopes, the vegetation forms a complete cover over the ground. A large part of the highlands below the snow line is covered with grasses and shrubs. In the northern highlands where rainfall is ample the result is tall bunch grass and shrubs, known as paramo. Where rainfall is less abundant, there is a cover of short grass, reaching less than six inches in height at maturity. This is the *puna*. In very dry areas or where the soil is very porous, the *puna* is mixed with a resinous plant known as *tola* shrub. In the canyon bottoms where evaporation is high and rainfall low, the common vegetation is a mixture of xerophytic shrubs and scrubby woodland. But in the low, rugged country along the border of Ecuador, the valleys and ridges alike are covered by a dense rain forest. The combination of narrow valley, steep slopes and wet luxuriant vegetation makes this area a major obstacle to transportation.

The upper limit of the forest on the eastern side of the Andes is between 10,000 and 11,000 ft. above sea level. At its upper limit the forest usually consists of a dense growth of lower trees which is given the colourful name of *ceja de la montaña*, or "eyebrow of the forest." In the zone of maximum rainfall there is a mountain rain forest, where the *ceja de la montaña* is especially dense. Below this is the beginning of the lowland tropical rain forest, or selva. The highest zones of selva are about 6,500 ft. above sea level, but in some places the lowland forest ascends to only about 3,000 ft. The lower mountain slopes, the cuesta zone and the eastern plains have an almost unbroken cover consisting of a great variety of species of evergreen broadleaf trees.

4. Animal Life.—The fauna of Peru can also be classified into that of the desert coast, the highlands and the eastern plains. Also, no account of Peru would be complete without pointing to the extraordinary wealth of marine life in the coastal waters. The chemical composition of this water, together with protection from too much sunlight, provides a perfect environment for a rich growth of microscopic organisms. These organisms provide the food base for an amazing number and variety of fish. Immense schools of small fish are preyed upon from below by larger fish, and from above by an incredible number of birds. There are pelicans, cormorants, gannets and other kinds of fish-eating birds that nest on the rocky islands and promontories along the coast. The excrement from these birds is called guano; it has long been used as a fertilizer and is one of Peru's most valuable natural resources. On one small island that was carefully studied by ornithologists it was found that the bird population amounted to 5,600,000. To feed so many birds requires at least 1,000 tons of fish per day.

In the highland region, the native animals include the American camellike species—the llama, the alpaca and the wild vicuña and guanaco. Rodents include the rabbit-sized mountain viscacha and the chinchilla, which is almost extinct in Peru. The Andean condor descends to the coast for carrion. The fauna of the montaña is that of the rest of the Amazon basin (*see* AMAZON: *Fauna*).

II. GEOGRAPHICAL REGIONS

Peru is sharply marked off into three major geographical regions, each with distinctive characteristics. First is the coast, mostly desert but highly productive, where water can be supplied; second is the Andean highland, complex in its pattern of landforms, where most of the people are subsistence farmers and herders but where commercial attention is centred on the minerals; and finally there is the rainy eastern part of the country, the montaña, very thinly populated but reputed to contain vast mineral wealth yet to be tapped.

1. Desert Coast.—The desert coast of Peru extends the length of the country from the border of Ecuador to the border of Chile. The characteristics of this unusual region and their causes are treated in another section (see *Physical Geography*, above). Two facts are fundamental to an understanding of what has happened on the coast: (1) very little of the land is flat, generally only where streams emerge from the mountains and build alluvial fans; and (2) the coast is so dry that even drought-resistant plants cannot survive except within reach of the water brought by the rivers. Of the 52 streams that descend from the Andes to the

Pacific coast in Peru, only 10 carry a sufficient volume of water so that they can reach the sea throughout the year. These are the rivers that rise far back in the mountains among the snow fields. The other streams dry up entirely during the dry part of the year. In these the first trickle of water reaches the coastal region in October or November. All the streams are at flood stage from December to March, while from August to October most of the channels are dry.

The native Indians practised agriculture in this region before the arrival of the Spaniards. The highland Indians, led by the Inca, conquered earlier settlers along the coast by cutting off their water supply. The Inca engineers greatly increased the irrigable area of the coast by building irrigation canals that tapped the water high in the mountains and by terracing the valley sides. The first result of the Spanish conquest, however, was the shift of workers from the production of food to the mining of gold and silver. The Indian irrigation systems were abandoned.

Only in the late 19th and in the 20th centuries was there a return of agricultural activity to the desert coast. About 1884, British-owned corporations began to build new irrigation works and to develop plantations of commercial crops. Cotton is grown in the northernmost oases of the coast, in the department of Piura. The oases in the department of Lambayeque (centring on Chiclayo) and in the department of Libertad (centring on Trujillo) are used chiefly for the production of sugar cane and rice. Farther south, where the coastal cloud cuts out much of the sunshine, sugar cane does not grow well, and cotton again becomes the chief crop. In the department of Ica, especially around the oasis of Ica, much of the land is used to grow grapes. Olives and grapes are grown around Moquegua.

There are several ports along this harbourless coast that serve the highlands. Matarani, near Mollendo, is a major port for southern Peru, as well as for a part of northwestern Bolivia. From the port of San Juan are exported the iron ores of Marcona. Lima and its port Callao are the chief urban centres of the country. In recent years Chimbote has become an important coal-exporting and steel-manufacturing centre. In the far north Talara is a major exporting port for Peru's oil. Copper is mined at Toquepala in southern Peru. The separate communities of the coast are connected with Lima by ship and, to an increasing extent, by motor truck along the new Pan-American highway, which extends the whole length of the region.

2. Highlands.—The complex physical character of the Andes mountains is paralleled by the complex pattern of human settlement in these mountains. Most of the inhabitants are Indian farmers and herders, and most of the crops are raised for subsistence rather than for commerce. The types of crops that can be raised in any community depend to a large extent on the altitude. Where temperatures are warm, at lower altitudes, the tropical crops include sugar cane, cotton, cacao, coca, rice and corn. At elevations above 8,000 ft. the crops are corn, wheat, barley, quinoa and potatoes. The latter crop is raised at higher altitudes than any of the others, reaching about 14,000 ft. in favourable places. A large part of the Andean highlands consists of a high-level surface, mostly unsuited for agriculture because of altitude or exposure to the winds. Only in the upper parts of the valleys and in small intermontane basins can agriculture be regularly practised. These areas are densely populated. In the southern part of the highlands, where not only is the high-level surface at an altitude above 14,000 ft. but also where the climate is semi-arid, the chief use of land is for the pasture of sheep and alpacas. The city of Arequipa has become the chief depot for the concentration of wool from the highlands.

Mining is another important activity of the highlands, and although a relatively small proportion of the population is employed in this work, the mines provide the chief commercial products and make the major contribution of the highland region to the total national production of Peru. The silver ores in the vicinity of Cerro de Pasco were discovered by the Spaniards in 1630, and silver was long the chief export. Silver declined in the 19th century when competition with Mexico put many Peruvian mines out of business. But in the 20th century mining has again

NANCY NENDERSON

ANDES MOUNTAINS NEAR HUANCAYO

flourished, though for other minerals than silver. Most important of these is copper, but there are also mines producing vanadium, bismuth, lead, zinc and gold. To the northwest of Cerro de Pasco there are several places where coal of good quality is mined.

The eastern slopes of the Andes have long suffered from difficulty of access to markets. In several valley basins at elevations below 8,000 ft. delightful climatic conditions are found, and it has been shown that crops could be produced in abundance. But because of the high cost of transportation only products of high value per unit of weight can profitably be sent across the mountains to the coast. In 1943 the first motor highway was completed. It extends inland from Lima to La Oroya and Cerro de Pasco, and then descends from nearly 14,000 ft. above sea level to only slightly more than 6,000 ft. at Huánuco. The road continues by way of the thriving frontier town of Tingo María (about 2,000 ft.), and then east from the mountains to Pucallpa on the Ucayali river, for a total distance from Lima of 842 mi. Other roads run from Lima to Tarma and to Satipo.

3. Montaña.—The wet, densely forested, lower eastern slopes of the Andes as well as the plains east of the mountains are included in the montaña. This region is still very thinly populated, since it was even more isolated than the valley basins of the eastern Andean slopes. The chief penetration of the montaña is along the highway to Pucallpa, described above. New settlers have occupied land along the road for the 288 mi. E. from Tingo María to the Ucayali. From Pucallpa, river boats run on regular schedules to Iquitos, the chief commercial centre of the montaña. In 1954 the Peruvian government granted land to a U.S. manufacturer of heavy earth-moving machinery. On this 1,000,000-ac. grant, the company hoped to establish pioneer farmers. The land has been partly cleared by a 110-ton "tree roller" which pushes over and chews up all but the largest trees. The residue is spread on the land as a fertilizer. The machine was technically a success, but in eastern Peru where labour is cheap the machine is more costly than men with machetes, axes and hoes. In the vicinity of this colony, on the Pachitea river, a short distance south of Pucallpa, oil has been discovered at Ganza Azul.

Another road to the montaña was started in 1959 from a place on the upper Urubamba river to reach an area suitable for agricultural settlement on the Madre de Dios river. The area was selected on the basis of geographical field studies, rather than by chance.

Eastern Peru is one of the last remaining places where speculators can search for Eldorado. The myth of great wealth awaiting the discoverer has persisted since early colonial times. It is true that eastern Peru could contain vast quantities of oil and that with enough capital investment its resources might bring wealth, but development of any sort would be costly. (P. E. J.)

III. THE PEOPLE

More than one-third of Peru's approximately 11,000,000 people live in cities, towns, villages and haciendas along the coast, while fewer than 350,000 live in scattered, small communities in the extensive jungles of the montaña, east of the Andes. The rest of the population, principally several million Quechuan-speaking and about 500,000 Aymara-speaking peoples, inhabits the valleys, basins and high plateaus of the Andes mountains. More than 50% of the population is rural.

1. Racial Types.—Continual and widespread miscegenation since early colonial times has resulted in the blurring of racial distinctions, and there is difficulty in making a classification on a purely biological basis. Three major categories—Indian, white and mestizo—are recognized, but their definition depends on considerations of cultural as well as biological criteria.

Less than 15% of the population is considered "white"; *i.e.*, of predominantly European (mainly Spanish) descent and with cultural characteristics associated with Hispanic or western society. The more than 45% of the population classed as "Indian" is predominantly of indigenous biological heritage, lives in the Andean highlands or the montaña, and has lifeways which are considered non-Hispanic. Between these two extremes are the mestizos who comprise almost 40% of the population and who exhibit a variety of cultural patterns which have evolved during centuries of contact between the native and europeanized societies.

Concentrated on the central coast are also thousands of people of predominantly Negro and Asiatic stock who constitute approximately 1% of the population. They are descendants of slaves imported in colonial times, and of Chinese and Japanese agricultural labourers contracted, respectively, during the second half of the 19th and the first decades of the 20th centuries.

2. Languages.—Spanish is the official language of Peru, but in the highlands and the montaña indigenous languages are spoken by millions of people. Spanish is the language of commerce and Peruvian *criollo* culture (*see* CREOLE); Quechuan and Aymara are the mother tongues of the highlands; Arawakan, Panoan and other languages are spoken by natives of the montaña.

Most individuals classed as "Indian" are able to speak some Spanish, and many are truly bilingual. Ability to speak Spanish fluently generally indicates membership in the mestizo category, however, since it is unusual that the national language is adopted without other cultural adaptations also taking place. The expanding educational and economic systems continue to carry the Spanish language and other features of national culture to the remoter parts of the country.

3. Religion.—Roman Catholicism is state sponsored but is not uniformly practised throughout the country. The Indians of the montaña have adopted few features of Catholicism, and in most highland villages the numerous *fiestas* and saints' cults are a tangle of pagan and Catholic beliefs and performances. The greatest adherence to Catholic doctrine and ritual is found along the coast and in the larger cities of the interior.

In the southern highlands and parts of the montaña, Protestant missionaries have made substantial inroads. Nevertheless, the cycle of Catholic *fiestas* continues to characterize the religious and recreational outlet for the vast majority of the population, and throughout Peru each hacienda, village and urban centre celebrates the feast day of its patron saint.

4. Cultural Variations.—The pre-Hispanic cultures of Peru have undergone considerable change in the four centuries of contact with western society. Indians have acquired new social and economic statuses and have become integrated into the larger society as peasant farmers, day labourers and sharecroppers on haciendas, and as craftsmen and servants. While rural cultures have changed, cities and towns have also become modified; new classes of skilled and unskilled workers, office employees, tradesmen and minor government officials have arisen. Many coastal cities are thriving commercial centres geared to an export-import economy of considerable proportions; and in the highlands numerous towns serve as focuses of market activity in the distribution of regional and imported products, and continually attract people from the surrounding rural areas.

The Montaña.—Indians of the montaña, although of diverse linguistic and cultural backgrounds, generally live in small communities, farm by means of a very simple technology, hunt and fish with bow and arrow, and manufacture much of their clothing and many of their tools, weapons and household utensils in traditional ways. For the most part, they form self-contained political and socioeconomic units which are much less involved in national patterns of culture than other segments of the population. Some of these people, however, work for wages on rubber, coffee, banana and coca plantations, where they are introduced to features of western culture. Many are also being actively missionized, although native religious and folk beliefs prevail.

The Highlands.—Mestizos and Indians form the bulk of the highland peoples, most of the former living in cities and towns and the latter in numerous agricultural villages or on large food-producing or cattle-raising haciendas. Both in the villages and on the haciendas, productive techniques tend to be simple adaptations of 16th- and 17th-century Spanish patterns to native practices. Field preparation and harvesting are laborious work, usually accomplished by co-operative labour groups. Corn (maize), potatoes, *oca*, barley and wheat are among the principal crops.

Labour is abundant, wages are very low, transportation is poor and the market for produce is largely local. Most haciendas have semifeudal social and productive arrangements, cultivate their holdings on a sharecropping system, and draw on the peasant villages for additional field labour. The best lands, comprising vast estates, are in the hands of a relatively few landlords; the steep, terraced hillsides are left to the subsistence crops of the peasant villages.

Through registration with the Peruvian government many peasant villages have gained some protection for their lands against the encroaching haciendas, and also a measure of autonomy over their internal affairs. Most villages are composed of a number of large extended families which traditionally controlled the use and distribution of community land; however, notions of private ownership are weakening the old communal system. Integrative forces such as extended kinship bonds, co-operative labour, the series of religious *fiestas* and other traditional mechanisms of village solidarity are also diminishing.

The Coast.—In the coastal valleys industrial mechanized agriculture reaches its peak in production, employment of wage labour and capitalization, but in the central coastal zone the more traditional system of sharecropping is still in force. Thousands of highland villagers are contracted for seasonal labour on the coast, where they form an important complement to the nucleus of permanent agricultural workers. They generally adjust to the dominant patterns of *criollo* culture and acquire an increasing awareness of their political and economic rights through contacts

NANCY HENDERSON

INDIANS BAGGING WHEAT IN A FIELD IN THE MANTARO RIVER VALLEY

with the heavily unionized and labour-conscious coastal population.

As in the highlands, the best lands are controlled by wealthy landlords, and the small, traditionally oriented and collectively organized indigenous community has virtually disappeared. In most valleys there are groups of small, independent farmers who grow mixed crops for market and whose operations and outlook are geared to the economic structure of the coast. A number of government-sponsored irrigation projects have made available thousands of additional hectares of farmland for small and medium-sized proprietors, a policy designed to increase food production and achieve a more equal distribution of land.

(L. C. Fa.)

IV. HISTORY

Man has lived in Peru since at least 8000 B.C. Beginning about 1250 B.C. several advanced cultures, such as the Chavín, Chimu, Nazca and Tiahuanaco, developed in different parts of Peru; however, the area was not unified politically until, in A.D. 1438, the Incas set out from their base in Cuzco on a career of conquest which, during the next 50 years, brought under their control the area of present-day Peru, Bolivia, northern Argentina, Chile and Ecuador. Within this area the Incas established a totalitarian state which enabled the tribal ruler and a small minority of nobles to dominate an inert population. (*See* Andean Civilization.)

1. Discovery and Exploration.—Spanish interest in the west coast of South America grew after Vasco Núñez de Balboa discovered the Pacific in 1513, but it was not until 1524 that Francisco Pizarro (*q.v.*), aided by another soldier, Diego de Almagro (*q.v.*), and a priest, Hernando de Luque, undertook explorations that led to the conquest of Peru. By 1527 they were convinced of the wealth of the Inca empire. Failing to win further co-operation from Panama's governor, Pizarro returned to Spain where he received authorization from Charles I to conquer and govern the area extending 600 mi. S. from Panama. When Pizarro, accompanied by his brothers, returned to Panama, Almagro was outraged by the vast powers Pizarro had acquired for himself. Nevertheless, he continued to collaborate. Pizarro embarked for Peru in early 1531 with 180 men. Establishing a base at San Miguel on the north coast of Peru, Pizarro crossed the mountains to make contact with the Inca Atahualpa, who had recently been victorious in civil war against his brother and was then residing near Cajamarca with an army of about 30,000. Atahualpa, scornful of the tiny band of invaders, accepted Pizarro's invitation to meet in Cajamarca. There, after Atahualpa had refused to accept Spanish suzerainty, he was taken prisoner. After his agents had collected a large ransom for his promised release, Atahualpa was executed for his presumed responsibility for the murder of his half brother Huáscar. (*See* Atahualpa.) As a means of controlling the Indians, Pizarro then recognized Manco Capac, Huáscar's brother, as Inca. In Nov. 1533 the Spaniards occupied Cuzco, the Inca capital, without a struggle.

A STREET IN CUZCO ON THE ROUTE OF ONE OF THE OLD INCA ROADS

2. Colonial Period.—The consolidation of Spanish control proceeded. The city of Quito (now in Ecuador) was subdued and Diego de Almagro left to conquer his domain of Chile. Pizarro organized a Spanish type municipal government for Cuzco and in 1535 established a new city, Lima, on the coast, to facilitate communications with Panama. Lands were allotted to the conquerors, who were provided with a labour force by grants of encomiendas, which enabled them to collect tribute from the Indians.

Serious trouble then erupted. An unsuccessful Indian rebellion led by Manco Capac in 1536 was followed by open conflict among the conquerors over the division of the spoils. Almagro, disillusioned by Chile's poverty, sought to seize Cuzco from the Pizarros. Almagro was defeated and executed in 1538, but his adherents continued to conspire with his son, and succeeded in assassinating Francisco Pizarro in 1541. However, an agent of the Spanish crown, sent to establish order, refused to recognize the younger Almagro, who was captured and executed in 1542.

But difficulties nonetheless persisted. The king of Spain, impelled by humanitarianism and by fear that the encomienda system might promote feudalism, promulgated in 1542 the New Laws. These laws threatened the existence of the encomiendas, which were so important to the conquerors. When Viceroy Blasco Núñez Vela arrived in Peru in 1544 to enforce the New Laws, the conquerors, led by Gonzalo Pizarro, revolted and executed the viceroy. Pizarro maintained power for two years until Pedro de la Gasca, a Spanish agent, undermined his power. Pizarro was executed in 1548.

It was nearly a decade before unruly conquerors were controlled under Viceroy Andrés Hurtado de Mendoza (1555–61), and not until the viceregal administration of Francisco de Toledo (1569–81) was systematic control of the huge Indian population attempted. Toledo adapted Indian institutions to the purposes of Spanish authority. Indian chieftains administered local Indian affairs according to custom but were responsible for collecting tribute and providing forced labour. Spanish agents (corregidors) were appointed to protect the interests of both crown and Indian in the Indian communities. Fearing that Manco Capac's son, Tupac Amaru, might prove dangerous to Spanish authority, Toledo ordered him executed in 1571.

By the end of Toledo's administration, the viceroyalty of Peru had assumed the form that it retained into the 18th century. Its territory included all of South America except Venezuela and Portuguese Brazil. Although ranching, agriculture and commerce were carried on, the mining of precious metals, particularly silver, was the basic industry, making the colony the most important in the Spanish empire. The discovery of the fabulous Potosí mines in 1545 had been followed in 1563 by the opening of the Huancavelica mines which produced the mercury essential to efficient processing of silver. Because the viceroyalty's mineral resources, except for the gold of New Granada (Colombia), were in Peru proper and Upper Peru (Bolivia), these areas became the most highly developed and richest. (*See* Potosí.)

The centre of wealth and power for the entire region was the viceregal capital of Lima. There, during the 16th and 17th centuries, a series of viceroys ruled over most of Spanish South America. The elaborate viceregal court was the apex of a highly stratified society based upon forced Indian labour. It attracted not only the politically oriented but also the wealthy, the artistic and the intellectual.

Lima was also important as seat of the *audiencia*, which administered royal justice, and as a religious, cultural and commercial centre. The archbishop of Lima was head of the church in Peru. Many religious orders established monasteries and convents there, and the tribunal of the Inquisition worked to extirpate religious heresy. In Lima also was the capstone of the educational system—the University of San Marcos—modeled on the University of Salamanca in Spain and offering courses in Indian languages as well as the more traditional subjects.

Adding to the wealth and importance of Lima was the privileged position which its merchants enjoyed under the monopolistic Spanish trade system. Lima, with its port of Callao, was the entrepôt for trade between Europe and the commercial centres of South America, ranging from Quito to Chile on the Pacific coast and to Buenos Aires (now in Argentina) on the Atlantic. Under the Spanish system the bulk of legitimate trade to and from these areas had to pass through merchants in Lima.

During the later 17th century Peru experienced difficulties. Some of these, such as increasing contraband trade with non-Spanish merchants, attacks by pirates and the growth of venality

among government officials, reflected the internal decay of Spain and the decline of its international power. But contributing importantly to Peruvian difficulties was the progressive decline of its production of precious metals.

Adding to Peru's problems in the 18th century was a series of governmental reforms. The Bourbon dynasty, which in 1700 had replaced the Habsburgs as rulers of Spain, undertook a program of reform during the 18th century, seeking to promote the economic development of their colonies, improve colonial defenses and provide more efficient government. The first seriously to affect Peru was the establishment of the new viceroyalty of New Granada, ending Peru's control over northern South America and resulting in its loss to New Granada of the thriving port of Guayaquil (now in Ecuador). For the next few decades Bourbon reforms improved conditions in Peru, but in 1777–78 the Spanish government established another viceroyalty, that of Río de la Plata, this time depriving the Peruvian viceroy of authority over Upper Peru and the areas of present-day Argentina, Paraguay and Uruguay. Chile was reconstituted as a virtually autonomous captaincy general. Following the disastrous loss of the silver mines of Upper Peru, the viceroyalty of Peru was still more weakened by reforms in the trade system which destroyed Lima's monopoly by permitting merchants in ports on the Atlantic and Pacific to trade directly with Spain.

To these blows was added internal strife. The Indians, who had from the time of the conquest suffered oppressive taxation and enforced labour, revolted in 1780 under Tupac Amaru II, a descendant of the last Inca and a man of wealth and education. The revolt spread throughout Peru and into Upper Peru and Ecuador. Although Tupac was captured and executed in 1781, the Indians continued to wage war against the Spaniards until 1783, causing disruption of economic life.

Nevertheless, in the late 18th and early 19th centuries Peru experienced a period of intellectual development that was the result of the influence of the utilitarian ideas of the European Enlightenment, brought to Peru in books and by European participants in scientific expeditions in 1778 and 1793. The chief manifestation of the intellectual development of Peru was the establishment of a literary and scientific club in Lima, the *Sociedad de Amantes del País*, which published a periodical, *El Mercurio Peruano de Historia, Literatura y Noticias Públicas*.

3. Achievement of Independence.—The Napoleonic invasion of Spain in 1808 sparked the Creoles (those of European descent born in America) in other Spanish colonies to struggle for independence between 1810 and 1821. But Peru remained loyal because of the conservative attitude of the Peruvian aristocracy, the presence of many Spaniards in Peru, the concentration of Spanish military power in Lima and the effectiveness of the viceroys in suppressing uprisings. Peru's independence was, consequently, achieved primarily by outsiders.

Among them was Gen. José de San Martín (*q.v.*) of Argentina, whose aims were to secure Argentine control of Upper Peru's silver from the Spanish forces which had occupied Upper Peru and to assure Argentina's independence by destroying the remaining Spanish power in South America. Because Argentine forces had previously been defeated in Upper Peru, San Martín determined to surround the Spaniards by liberating Chile and using it as a base for a sea-borne attack on Peru. Chile was freed in 1818, and a fleet was readied which enabled San Martín to occupy the Peruvian port of Pisco in Sept. 1820. When the viceroy withdrew his forces into the interior, San Martín entered Lima. Peruvian independence was declared on July 28, 1821.

Lacking power to attack the strong Spanish forces in the interior, San Martín sought aid from Simón Bolívar, who had recently liberated northern South America, but failing in this attempt returned to Argentina. Peruvians then called upon Bolívar, who assumed supreme power in Peru. At the battles of Junín (Aug. 6, 1824) and Ayacucho (Dec. 9, 1824) Spanish power was broken and Peru's independence assured. Bolívar continued to rule Peru until his return to Colombia in 1826.

Between that time and the mid-1840s Peruvians sought to govern themselves. They were handicapped by economic dislocations caused by the wars for independence, by the departure of able loyalists after Spain's defeat and by a population which was little suited to self-government. The revolution had wrought little social change so that the vast majority of the population, the mestizos and Indians, were economically depressed and illiterate, did not speak Spanish and continued to live much as had their ancestors under Inca rule. The professional and landholding minority possessed elements of education and economic independence but lacked experience in, and the traditions of, self-government. In such a vacuum political power fell to military leaders who had achieved prominence during the revolutions for independence. Their bitter rivalries, particularly those among Agustín Gamarra, Felipe Santiago Salaverry and Luis José Orbegoso, resulted in civil wars which brought Peru close to political anarchy in the early 1830s.

4. Santa Cruz and Castilla.—The ambitions of Gen. Andrés Santa Cruz, who had briefly governed Peru after Bolívar's departure and had then become dictator of Bolivia, complicated Peru's position. Santa Cruz desired to unite Peru and Bolivia into a single powerful nation. In 1835, taking advantage of Peru's disorder, Santa Cruz intervened with force. Within a year he had established the Peruvian-Bolivian confederation, with himself as president. Chile, fearing that this superstate might dominate it or at least curtail its growing commerce, declared war on the confederation in 1836. Although Argentina also declared war on the confederation, it did little active fighting, and it was Chilean forces, supported by Peruvian *émigrés*, that defeated Santa Cruz and restored independence to Peru and Bolivia in 1839.

After the collapse of the confederation, Peru lapsed into internal disorder, but in 1844 mestizo Gen. Ramón Castilla defeated rival military leaders and established undisputed control over the country. Between then and 1862 Castilla dominated Peruvian politics, giving the country unprecedented political stability and material progress. Castilla was aided by the discovery that the guano deposits, found in large quantities in Peruvian territory, had high commercial value as fertilizer. He established a government monopoly which during the next few decades brought large and progressively increasing revenues to Peru. With this wealth Castilla reorganized Peru's finances and began payment on the foreign debt. Internal communications were improved and Peru's first railroad, connecting Lima and Callao, was constructed. Attention was paid to the development of public education, and the military and naval power of the nation was strengthened. Slavery and the payment of tribute by Indians were abolished.

5. Economic Depression.—When Castilla left office in 1862, political disturbances mounted. Corrupt politicians squandered guano revenues instead of using them constructively. Peru experienced increasing financial crises. To make matters worse, a Spanish fleet, in retaliation for Peru's supposed maltreatment of Spanish citizens, seized the valuable guano-producing Chincha Islands. In the ensuing naval war, Chile, Ecuador and Bolivia joined Peru in fighting Spain. Hostilities ended when the Spanish fleet withdrew from the Pacific after the bombardment of Callao in May 1866, but a truce was not signed until 1871 and a formal peace treaty between Peru and Spain was not concluded until 1879.

In the meantime Peru's financial position deteriorated. Pres. José Balta (1868–72) found it necessary to mortgage anticipated guano receipts to meet current expenses. He then proceeded to increase Peru's indebtedness to the staggering sum of $240,000,000 (United States currency) to finance a network of costly railroads. His successor, Manuel Pardo (1872–76), Peru's first civilian president, took over a nearly bankrupt nation, and conditions became worse when the price of guano declined. Pardo sought to solve the problem by cutting military expenditures, reducing the number of government employees and establishing a government monopoly over the thriving nitrate industry in the province of Tarapacá. But Peru's financial problems had not been solved when it entered the War of the Pacific in 1879.

6. War of the Pacific.—Although this war originated in a dispute between Bolivia and Chile, Peru became involved because it had signed a treaty of alliance with Bolivia in 1873. Because Peru was the more powerful of the allies as well as Chile's traditional

rival, Peru carried the main burden of the war. Almost from the beginning, Peru suffered one major defeat after another at the hands of Chile. After Lima was captured in Jan. 1881, Chilean forces occupied the city for nearly three years while an attempt was made to impose Chilean peace terms. Finally, on Oct. 20, 1883, the treaty of Ancón was signed; under its terms Peru ceded its nitrate province of Tarapacá to Chile and agreed that the Peruvian provinces of Tacna and Arica would be occupied by Chile for ten years, at which time a plebiscite was to be held to determine their nationality. (*See* TACNA-ARICA DISPUTE.)

With its economy suffering from war's destruction and dislocation, its public debt increased and its revenues reduced by the loss of Tarapacá, Peru struggled to recover. A major step was taken in 1890 when Peru's foreign creditors organized the Peruvian corporation, which assumed responsibility for the nation's foreign debt. In return, the corporation received control of the national railroads for 66 years, together with other benefits.

7. Peru in the 20th Century.—During the next 40 years Peru's economy expanded significantly. Internal communications were improved, foreign investors exploited Peru's mineral resources, and copper and oil production rose. The opening of the Panama canal stimulated expansion of the economy, as did the large influx of United States capital in the 1920s. Peru's exports increased from $22,000,000 in 1900 to $134,000,000 in 1929, indicating the extent of economic growth.

During this period Peru was governed by an oligarchy of landowners, military figures and the newly rich. Outstanding among them was Pres. Augusto B. Leguía y Salcedo (*q.v.*; 1908–12; 1919–31), who promoted material development with the aid of U.S. capital. Although Leguía officially advocated reform, in reality he ruled as a dictator in the interests of an oligarchy that cared little for improving the condition of either the Indians or the urban workers and middle classes, which were growing in numbers as the economy expanded. The reform movement of the 1920s developed from these circumstances.

This important movement, nurtured by the ideas of the Peruvian Manuel González Prada (1844–1918) and the influence of the Russian and Mexican revolutions, was led first by Víctor Raúl Haya de la Torre (*q.v.*) and José Carlos Mariátegui. The two parted company in the mid-1920s when Mariátegui assumed leadership of the Communist party while Haya de la Torre continued to head the indigenous reform movement known as Apra (*Alianza Popular Revolucionaria Americana*). Apra's program demanded increased industrialization; regeneration of the Indian through land reform, labour organization and welfare legislation; and an "anti-imperialist" policy of nationalization of Peru's resources. Made illegal by Leguía, Apra operated clandestinely. When Leguía was overthrown in 1931, in the middle of a serious depression, Haya de la Torre became a candidate for the presidency. Haya's supporters claimed electoral victory, but his opponent, Col. Luis Sánchez Cerro, seized power and again outlawed Apra. When Sánchez Cerro was assassinated in 1933, he was replaced by Gen. Oscar R. Benavides, who was given dictatorial powers by congress when it appeared that Apra would win the election of 1936.

Benavides' successor, Manuel Prado y Ugarteche (1939–45), guided Peru through an international crisis provoked by a Peruvian invasion of Amazon territory in a dispute with Ecuador (1941) and through the difficult period of World War II when Peru sided with the Allies. In internal affairs Prado, an enlightened member of the oligarchy, extended public education, encouraged the unionization of labour and attempted to ameliorate the suffering of Peru's depressed majority. To implement his program he sought to increase Peru's productivity by encouraging rapid economic development, including hydroelectric and irrigation projects, exploitation of untapped resources and industrialization.

Prado's principles were followed during succeeding administrations, and as a result Peru's economy underwent rapid expansion in the postwar years. With this expansion came growing political and social unrest. The demands of the working and middle classes for a greater share of the national wealth in the form of higher wages and social and educational benefits became more insistent and grew in intensity under the impact of national and international inflationary pressures. These demands for socioeconomic reform were resisted by the ruling oligarchy: the more reactionary wing opposed any change that would lessen its privileges; the more liberal recognized that change was necessary if Peru were to become a modern nation but wished to proceed much more slowly than did the reformers. From these sources arose political conflicts that characterized Peruvian history from the Prado administration into the 1960s.

In 1945 Prado had permitted Haya de la Torre to again become active in Peruvian politics. The Apra party played an active role in the campaign preceding the free presidential election of 1945, but rather than nominating Haya the party joined in a coalition, the National Democratic Front, whose candidate was José Luis Bustamante y Rivero, a conservative but not a reactionary. Not only was Bustamante elected but a number of Apristas won seats in congress. Because of Apra's evident power, Bustamante gave three cabinet posts to Apristas. However, after two years of moderate progress in the areas of education, housing and economic development, conflict developed between the Apristas and the more conservative members of the government. The Aprista members of the cabinet were forced to resign in 1947 following an accusation of Aprista complicity in the assassination of the editor of the anti-Aprista newspaper, *La Prensa*. The following year Apristas in the navy attempted an unsuccessful revolt, and Bustamante retaliated by outlawing the party. More reactionary elements wished further retaliation and in 1948 seized the government by force, placing Gen. Manuel Odría in the presidency. Aprista leaders were either imprisoned or sent into exile in the attempt to destroy the Apra movement. Haya de la Torre eluded the police for a short time but was finally forced to seek asylum in the Colombian embassy in early 1949. His presence there resulted in a bitter dispute between Colombia and Peru, with the latter claiming that Haya was a common criminal who should not be granted asylum. The matter reached the International Court of Justice where a decision by arbitration failed to solve the problem; however, in 1954 Haya was permitted to leave Peru.

The major source of opposition having thus been eliminated, Odría was elected president of Peru in 1950. Dictatorial techniques were used to keep opposition under control and to maintain internal order; nevertheless, the Odría administration did not ignore the working classes. Wage increases, an extended social security program, a few low-cost housing projects and some improvements in the education system were accomplished. Odría's overwhelming concern was, however, to augment economic development. In this area his administration, assisted by technical aid from the United States, North American capital and higher prices for Peru's exports resulting from the Korean War, made significant progress. Efforts to develop agriculture brought a 25% increase in food production between 1950 and 1955. Work was begun on the construction of a steel mill at Chimbote. Highways and railroads were improved and extended to meet the needs of the expanding economy. Concessions were made to encourage foreign capital to exploit further Peru's mineral resources, with the result that oil production soared and a new copper deposit was located in southern Peru. To assure financial stability during this economic expansion the Odría administration hired a firm of United States consultants to make recommendations which were put into operation.

In 1956 Odría, lacking the full support of the oligarchy, permitted a presidential election. That the election was relatively free of government intervention was shown in the extremely poor showing of Hernando de Lavalle, who had Odría's support but ran last. Runner-up was a young architect, Fernando Belaúnde Terry, candidate of a hastily organized People's Action party, who entered the race at a late date and campaigned on a vaguely defined reform platform. Winner was former president Manuel Prado y Ugarteche, candidate of the Peruvian Democratic Movement and supported by Apra, which in spite of extreme repression had continued to organize and operate clandestinely. Following his election Prado legalized Apra, thus recognizing not only his personal political indebtedness to the party but also the im-

portance of Apra as a force in Peruvian politics.

Prado's administration sought to establish a democratic regime which would both promote economic development and bring gradual improvement in the conditions of the underprivileged. Educational facilities were extended, more lands were placed under irrigation and the Chimbote steel mill was completed. Nevertheless, the administration met serious difficulties as the 1950s drew to an end. The decline in price of Peru's major exports brought a sharp reduction in badly needed government revenue and dollar reserve. At the same time the cost of living rose steadily, arousing social discontent and precipitating a series of strikes. On several occasions, under pressure from either the left or the right, it was necessary to reorganize the cabinet. However, at the end of 1959 a degree of stability was achieved partly as a result of loans from the United States and international agencies and partly because of the success of an austerity program effected by Pedro Beltrán, who became premier in July 1959.

Elections for president and congress took place in June 1962. Of the three major candidates for president, Haya de la Torre, Belaúnde Terry and Odría, none received one-third of the popular vote, the total necessary for election. Under the Peruvian constitution, the election then went to congress for decision. The majority party in congress was Apra, the party of Haya de la Torre. However, before congress could act, the armed forces, fearing the possibility that their traditional foe Haya would be elected, seized the government by force on July 18. Pres. Prado was imprisoned, congressional sessions were suspended and the elections were annulled. Charging that the election had been dishonest, a four-man military junta headed by Gen. Ricardo Pérez Godoy took control of the government. Prado was freed and exiled, and the junta promised new elections in June 1963.

Pérez Godoy led the junta until March 1963 when he was ousted and replaced by Gen. Nicolás Lindley López. In June 1963 the general election took place, as promised by the junta. The presidential candidates again were Haya de la Torre, Belaúnde Terry and Odría. With the combined support of the Popular Action and Christian Democratic parties, Belaúnde Terry won the election, receiving about 40% of the vote. The two parties supporting him gained a plurality of congressional seats. Belaúnde Terry promised co-operation with the U.S. and the Alliance for Progress. (R. N. Bu.; X.)

V. POPULATION

1. Number and Distribution.—A census taken in 1961 enumerated a total of 10,364,620 inhabitants in Peru, about 20.9 persons per square mile. These figures do not include an unenumerated group of about 700,000 and the forest Indian population, which was estimated to be about 300,000. Since that time, due to a birth rate of about 45 per 1,000 and a death rate of less than 20 per 1,000, the total probably has increased by about 300,000 persons per year.

Peru's population is heavily concentrated in the high valleys between the ranges of the Andes and at a few locations on the Pacific coastal plain where streams from the mountains make their way to the ocean. In this coastal area the settlements centring in Lima and Callao, Trujillo, Piura, Sullana, Chiclayo, Pisco, Ica, Moquegua and Tacna deserve special mention. The extensive sections of the country which lie east of the Andes are very sparsely populated (*see* Table), although the cities of Iquitos, Lamas, Moyobamba, Pucallpa, Tarapoto, Tingo María and Yurimaguas are centres of zones having several thousand inhabitants.

The majority of Peru's people live amid rural surroundings, as is evidenced by the fact that in 1961 about 53% of the population resided in places having fewer than 2,500 inhabitants. The capital, Lima, is by far the largest city with a 1961 population of 1,715,971. Callao (161,286), Arequipa (156,657), Trujillo (99,808), Chiclayo (86,904) and Cuzco (78,289) are next in size among Peruvian cities.

2. Composition.—American Indians, whites and mixtures of the two (mestizos) constitute the overwhelming proportion of the Peruvian population (see *The People*, above).

*Area, Number of Inhabitants and Density of Population, 1961 Census**

Zones and Departments (with capitals in parentheses)	Area (in sq.mi.)	Urban Population	Total	Persons per sq.mi.

Total	496,222†	4,877,839	10,364,620	20.9

*Preliminary.
†Total includes 1,928 sq.mi. of islands and inland water.

Because of the very high birth rate and the comparatively high death rate prevailing in Peru, the population is highly concentrated in the younger years of life. Thus in 1955, 44% of the population was less than 15 years of age, 53% aged 15–64, and only 3% aged 65 or more; and there is slight likelihood that these proportions have changed significantly since that time. In 1961 the sexes were approximately equal in number, there being a ratio of 99 males per 100 females. (T. L. Sh.)

VI. ADMINISTRATION AND SOCIAL CONDITIONS

1. Government.—The country's chief executive is its president, who holds office for six years but cannot be re-elected immediately. Two vice-presidents and a cabinet of 12 assist him in his duties. The legislative authority belongs to congress, which consists of a senate and a chamber of deputies. In accordance with the constitution of 1933 and its subsequent amendments, presidential and congressional elections are held every six years when direct popular vote determines the country's government. It is the president's privilege to select his cabinet and to provide congress with panels of names which are to guide members of the legislature in appointing justices for supreme court duty and in filling high church positions, in the last case subject to Vatican approval. Voting, compulsory for all literate male citizens between 21 and 60 (married persons who have reached 18 years of age are eligible to vote), was extended during the presidential elections in 1956 to include women for the first time.

Senators and deputies are elected also by popular vote, the former in the departments, the latter in the provinces. Congress sits for four months each year and its deliberations are translated into action by 12 ministries: interior (which includes police, postal and telephone service), foreign affairs, justice and worship, public education, finance and commerce, war, navy, aviation, development and public works, public health and social welfare, agriculture, labour and Indian affairs.

Peru is divided into 12 judicial districts in which justice is administered by superior and minor courts. The highest court of the land is the supreme court at Lima, the members of which are chosen by congress.

2. Welfare Services.—Peru has a social security program providing for health and maternity benefits, compensation for workmen injured during the course of their employment, and allowances for the aged and indigent. In dealing with these and similar problems, Peru has been participating in the technical assistance programs offered by the United States on a bilateral basis and by the United Nations on a multilateral basis.

3. Education.—Primary education is free and obligatory for

children from 6 to 14. While about 88% of all primary schools are public, almost two-thirds of the secondary ones are operated by private institutions, frequently with religious affiliation, or maintained by colonies of foreign residents. There are also more than 150 trade schools, emphasizing agricultural, industrial or commercial subjects. The University of San Marcos was founded at Lima in 1551 and the first printing press was set up in that city in 1584, about half a century after it had been introduced into Mexico and 50 years before it was to appear in the regions north of the Rio Grande. In addition to the national University of San Marcos, there are three small national universities at Trujillo, Arequipa and Cuzco (in order of student enrollment) and a Roman Catholic university at Lima.

4. Defense.—Military conscription is the law of the land and, in theory, every male Peruvian citizen is obliged to serve 2 years in the active army, 10 years in the reserve army and 20 years in the national guard. The draft, however, is not usually enforced, and the active army numbers approximately 30,000 men, consisting in the main of volunteers. Army, navy and air force are U.S.-trained and, following World War II, their equipment underwent a substantial expansion and modernization, chiefly through purchases from the U.S. and Britain. The president is the supreme commander of the nation's armed forces, exercising his authority through the secretaries of war, navy and aviation. (G. I. B.)

VII. THE ECONOMY

1. Production.—Agriculture is the leading economic activity of Peru, engaging about 60% of the nation's employed population. In terms of value, cotton is the country's most important commercial product. It is of the long-staple Tangüis, Pima and Karnak varieties. Tangüis cotton is grown chiefly in the coastal valleys around Lima; the Pima and Karnak cotton is produced in the coastal valleys of northern Peru. The second most important commercial agricultural product, sugar, is cultivated chiefly in the coastal valleys near Trujillo and Chiclayo. In addition to cotton and sugar, the irrigated coastal area produces rice. The temperate zone staples—wheat, corn (maize), barley, oats, potatoes and alfalfa—are grown in the Andean highland region. The so-called Irish potato, in fact, probably originated in the Peruvian or Bolivian Andes. In the montaña east of the Andes small amounts of sugar cane, tobacco, coffee, cacao and bananas are produced. Also grown in the montaña is the coca leaf (source of cocaine), which is chewed by the Indians of the high Andes. The rubber tree *Hevea brasiliensis* is found in the province of Loreto in the upper Amazon valley, though production has not been large in recent decades. A program involving considerable technical assistance to Peruvian agriculture was begun in 1943 by the Cooperative Interamerican Service for Food Production (S.C.I.P.A.), an organization jointly sponsored by the Peruvian and U.S. governments.

MINERAL RESOURCES AND THE AGRICULTURAL AND INDUSTRIAL AREAS OF PERU

Peru has a livestock industry of moderate size. Cattle raising is spread throughout the country, while sheep raising occurs on a considerable scale in the south near Lake Titicaca and Cuzco. The llama and alpaca, animals related to the camel but smaller, are raised for their wool and as beasts of burden, providing a unique aspect to the livestock industry in that part of the world. Sea birds such as the cormorant provide another novel feature. The bird droppings are left in large quantities on the exceedingly dry islands off the coast and are collected as guano, a rich fertilizer. Guano marketing has been handled by a government monopoly, the Compañía Administradora del Guano. Production of this fertilizer has been important since the middle of the 19th century, when it represented Peru's chief export.

Peru has always been a major mining country. Gold and silver have been important since colonial times; however, since the latter part of the 19th century, copper, lead and zinc have overshadowed the precious metals in importance. Peru also produces considerable quantities of tungsten, vanadium and bismuth. The chief mining company has been the United States-owned Cerro de Pasco corporation, most of whose operations have been in the Andes just east of Lima. In 1956, however, the Southern Peru Copper company began to work a new major deposit at Toquepala, south of Arequipa. Also in the middle 1950s iron ore production

in the area around Ica became commercially significant. Much of the ore began to go to the new steel mill at Chimbote, but some was exported. Peru has also mined and exported some coal. Crude oil production has occurred chiefly in the northwest corner of the country near Talara. There has also been a limited amount of production in the upper Amazon valley.

Bonito, tuna and swordfish are caught in the Humboldt current off the coast of Peru. The Peruvian coastal waters are among the favourite areas of the world for sports fishermen. The confluence off the northwest corner of Peru of the cold Humboldt current and the warm ocean current from the north provides unique and favourable fishing conditions.

The rivers that rise in the Peruvian Andes and flow east provide major opportunities for power development, but by the middle 1960s there had been little development of their hydroelectric potential. One important project has been the dam built on the Santa river in connection with the construction of the steel mill at Chimbote. Another important project, completed in 1956, was the diversion of the Chotano, a tributary of the Amazon, through a tunnel into the Chancay river above Chiclayo.

A major development in Peruvian industrialization was the opening of the steel mill at Chimbote in Aug. 1956. The manufacture of industrial explosives was also begun in that year. However, textiles and food processing have been the most important industries in the country for many years. Manufacturing has been concentrated mainly around Lima, Callao, Arequipa, Trujillo and Chiclayo. Following World War II the government of Peru took an active interest in encouraging industrialization.

2. Trade and Finance.—Peru's chief imports are heavy manufactured items such as electrical machinery, motor vehicles and iron and steel products. Other imports include chemicals and pharmaceuticals. The chief exports are cotton, sugar, copper, iron ore, petroleum and fish. The United States generally provides about 50% of Peru's imports and takes about 35% of its exports. Considerable trade is also carried on with the United Kingdom and West Germany. Peru has provided high tariff protection for its domestic textile industry and has also imposed quotas on automobile imports. But import restrictions are, in general, less rigorous than those of many other Latin-American countries.

The monetary unit of Peru is the sol. The official par value, which had been 6.5 soles per $1, was suspended in 1949, and a system which provided for fluctuating rates of exchange was established. In the mid-1960s the rate was about 25–30 soles to $1.

The Banco Central de Reservas has functioned as the central bank of Peru since the 1920s, when it was set up with the standard functions of a central bank. It has the customary credit control powers, the note issue privilege, and serves as financial agent for the government. The rediscount rate of the central bank was set at 6% in 1947.

3. Transport and Communications.—In the middle 1960s there were about 25,000 mi. of roads, of which about 5,700 mi. were surfaced. The principal highway in Peru is the Peruvian part of the Pan-American highway, which follows the Pacific coast line from Tumbes on the Ecuadoran border to Tacna on the Chilean border. Another important highway extends east from Lima over the Andes to Tingo María and Pucallpa; from there it is possible to continue by river boat to Iquitos.

The chief railroads of Peru were built between 1850 and 1880. The Southern railway extends from the port of Mollendo to Arequipa, Puno on Lake Titicaca, and Cuzco. It has been a chief means of entry to Bolivia. The Central railway was built from Lima across the Andes to Cerro de Pasco and Huancayo. The Central crosses the Andes at an elevation of 15,865 ft. Henry Meiggs made an engineering reputation as the builder of the Central and the Southern railroads. As of the mid-1960s Peru had no railroad linking the northern and southern parts of the country.

The chief port of Peru is Callao (*q.v.*). The United States-owned Grace line has been a major ocean-shipping company and an important element in the Peruvian economy since the middle of the 19th century. Much of the cargo moving through Peruvian ports is handled by foreign ships, but some is serviced by the government-owned Corporación Peruana de Vapores.

Inland waterways are nonexistent along the Pacific coast and in the high Sierras; in the montaña, however, the upper tributaries of the Amazon—the Marañon, Ucayali and Huallaga—represent, except for the airplane, the only means of effective communication. Iquitos (*q.v.*) is the chief river port in that region.

Peru has a well-developed system of airlines, both international and domestic. Especially important has been the air link across the Andes from Lima to Iquitos. The Faucett Aviation company has been the chief domestic airline.

The Compañía Peruana de Teléfonos, an International Telephone and Telegraph company subsidiary, provides telephone service in the Lima area. In the mid-1960s there were more than 2,000,000 radios and 70,000 television sets in Peru. Radio stations were maintained in many of the larger towns, and television networks were located in Lima and Arequipa.

PERUGIA (ancient Perusia), a city and seat of an archbishopric, and capital of the province of Perugia in Umbria, central Italy. It is 172 km. (106 mi.) N of Rome by road and is finely situated on an irregular cluster of hills, 1,617 ft. above sea level, west of the Umbrian Apennines. The view from the city embraces the Umbrian Valley, part of the central Tiber Valley, and the Lago Trasimeno Valley. Pop. (1961) 113,880 (commune). The great period of Umbrian art, in the 15th century, was centred in Perugia. There are considerable remains of the Etruscan walls with three gateways, the Marzia, the Arco d'Augusto (partly rebuilt in the 1st century B.C.), and the Trasimena (reconstructed in the 14th century). The Etruscan nucleus is enclosed by 13th-century walls, narrow, winding, and steep streets, and more modern quarters.

The town retains its five historic wards of Porta San Pietro, Porta Eburnea, Porta Santa Susanna, Porta Sant'Angelo, and Porta Sole, to which a sixth, Fontivegge, has been added. The centre of the city lies on a north-south axis formed by the Corso Vannucci. In the beautiful Piazza Quattro Novembre is the Palazzo dei Priori (Palazzo Comunale, 13th–16th centuries), bearing over the doorway two 13th-century bronze figures, the griffin, emblem of the town, and the Guelph lion. Its Sala dei Notari has 13th-century frescoes by Pietro Cavallini, and the Galleria Nazionale dell'Umbria is a remarkable collection of paintings and sculpture of the Umbrian school. The adjoining Biblioteca Comunale Augusta has a collection of manuscripts and incunabula. Also in the Piazza Quattro Novembre is the cathedral of S. Lorenzo (1345–1430) in which is the supposed white onyx espousal ring of the Virgin. In the centre of the piazza is the Maggiore Fountain (1278), a splendid work by Fra Bevignate with bas-reliefs by Nicola and Giovanni Pisano. The hall of the Collegio del Cambio (1452) in the Corso Vannucci contains a dazzling series of frescoes by Pietro Perugino and his pupils. In the Piazza Matteotti are the Palazzo dello Studio (15th century) and the Gesù Church (16th–17th centuries). Other churches of interest are S. Angelo (6th century, on a circular plan), S. Prospero (8th–16th centuries), S. Pietro (10th–16th centuries, with walnut stalls of 1535), Sta. Maria Nuova (13th–16th centuries), Sta. Agata (14th century), S. Domenico (14th century, rebuilt in the 17th), containing the monumental tomb of Pope Benedict XI, S. Ercolano (14th century), S. Severo (15th–18th centuries), with a fresco by Raphael, and S. Filippo (17th century). The oratory of S. Bernardino (1457–61) has an early Renaissance facade by Agostino di Duccio. In the former convent of S. Domenico is the Archivio di Stato and the Etrusco-Roman Museum with an important collection of Etruscan objects. The Museo del Duomo is a small medieval museum. The former convent of the Olivetans (18th century) is the central seat of the university (founded in 1308), and in the Palazzo Gallenga is the Italian university for foreigners. On the outskirts of the city are the Etruscan hypogea of San Manno and of the Volumnii (2nd century B.C.).

Perugia is served by the Foligno-Terontola railway, and the central Umbrian railway from Sansepolcro to Terni. A network of motor coach lines joins Perugia to all the provincial centres as well as to Rome, Florence, and the Adriatic riviera. The chief economic activities are agriculture, food industries (milling, *pasta* manufacture, confectionery), and the clothing industry (textiles and ready-made clothing).

The town was founded by the Umbrians and became one of the 12 Etruscan strongholds. From 310 B.C. it belonged to Rome and was the latter's auxiliary in the war with Hannibal. During the conflict between Mark Antony and Octavian (later the emperor Augustus) it was taken by the latter, burned by its citizens, and rebuilt by Augustus later. In 592 it became a Lombard duchy and subsequently was involved in many petty conflicts with neighbouring towns, Perugia usually taking the Guelph side. In 1416 the *condottiere* Braccio Fortebraccio took it; later the rival families of the Oddi and the Baglioni fought there for power. From 1540 Perugia was a possession of the church and a papal governor was installed. In 1809 the French captured it, but it was restored to the church in 1815. Perugia played an active part in the Risorgimento of June 1859 and in the following year formed part of a united Italy.

Perugia Province (area 2,446 sq.mi. [6,335 sq.km.]; pop. [1961] 555,608) comprises part of the sub-Apennines to the west of the Umbro-Marche crests of the Apennines, and is mountainous and hilly except for the flat zones of the Umbrian Valley and of the central Tiber Valley, and the Città di Castello and Gubbio Plain. The chief crops are wheat, maize (corn), olives, grapes, forage, beetroot, tobacco, and tomatoes. The main industries are printing, tobacco curing, and the production of *pasta,* building materials, agricultural machinery, and majolica. The fisheries of Lago Trasimeno are important.

Apart from Perugia city, the chief centres, all of interest artistically, are Assisi (pop. [1961; commune] 25,361), Foligno (48,684), Spoleto (38,563), Todi (19,768), Città di Castello (35,788), and Gubbio (29,976). The province is crossed by the Ancona–Rome, Foligno–Terontola, and Sansepolcro–Terni railways.

PERUGINO (Pietro di Cristoforo Vannucci) (*c.* 1450–1523), Italian artist, the principal painter of the Umbrian school and the master of Raphael, was born at Città della Pieve, near Perugia, from which city he takes his name. Giovanni Santi, Raphael's father, says that Perugino and Leonardo da Vinci were "of an age." It is known that Leonardo was born in 1452 and entered the guild in Florence in 1472, in which year Perugino was also registered; it is likely, therefore, that he was born about 1450. On the other hand, G. Vasari implies that he was born in 1445 or 1446, but this seems less likely than Santi's date. Nothing is known for certain of his early training, but he may have been a pupil of Fiorenzo di Lorenzo in Perugia and of Piero della Francesca in Arezzo, in which case he would have been a fellow pupil of Luca Signorelli. Certainly the two men were acquainted, and an occasional influence from Signorelli is visible in Perugino's work, notably in the direction of an increased hardness of drawing (*e.g.,* "Crucifixion and Saints"; Uffizi gallery, Florence). In Florence he almost certainly worked in the shop of Andrea del Verrocchio, where Leonardo was then also active.

The first certain work by Perugino is a "Saint Sebastian," at Cerqueto, near Perugia, the sole survivor of a series of frescoes in the church, recorded as having been signed and dated 1478. This already shows much of his typical style, and he must have made a considerable reputation by that date, since he is next recorded in 1478–79 in Rome, working in old St. Peter's for Pope Sixtus IV. These frescoes are lost, but the same pope employed him on the fresco decoration of the Sistine chapel, and his name occurs in the documents of 1481 and 1482. Several of his frescoes have been destroyed—most notably those on the altar wall, thrown down to make way for Michelangelo's "Last Judgment"—but his most important work there, the "Giving of the Keys to St. Peter," is fundamental to his development. It shows the apostles

ranged in the foreground, watching Christ hand the keys to Peter; in the background is a centrally planned building, of the type then much in favour among advanced architects. It symbolizes the Old Dispensation, since it represents the Temple at Jerusalem, and the giving of the keys is a symbolic representation of the New, or Christian, Dispensation. The artistic importance of this fresco is very great, for it is simple and lucid in arrangement, and the first glance reveals the main action; by comparison, the frescoes by Botticelli in the same series appear both crowded and incomprehensible. It was Perugino's main claim to fame that he insisted on the qualities of simplicity and clarity that were to characterize the High Renaissance and, in particular, the work of his pupil Raphael. It cannot be denied that among Perugino's very numerous works there are several that are less lucid and simple than insipid and vacant, but his not infrequent sentimentality should not obscure his merits and his historical importance.

Immediately after completing his work in the Sistine chapel, Perugino went back to Florence, where he was given a commission to work in the Palazzo della Signoria, and in 1491 he was invited to sit on the committee concerned with finishing Florence cathedral; in the same year he signed and dated the triptych now in the Villa Albani, Rome. There are several signed and dated works from the next decade, some of the principal ones being the "Madonna and Saints" (1493, Uffizi) and the same subject, also of 1493, in Vienna; in 1494 he painted a portrait of Francesco delle Opere (now in the Uffizi), which shows that he must have been well acquainted with Flemish portraits of the later 15th century, since the influence of Hans Memlinc is unmistakable. The "Pietà" (1495; Pitti, Florence) shows the calm resignation which his style was capable of expressing.
